Claude is an instance of what may be done by a constant and diligent study of nature, and by unwearied manual practice. It was his custom to spend great part of his time, often whole days, from dawn till night, in watching the changes of the effect on earth and sky. He has left proofs of the painstaking labour with which he studied the details of a picture in finished studies of leaves and bits of ground. By these means, although he is said not to have shown any particular quickness in his early progress, he acquired such mastery of hand and eye as produced him fame, wealth, and the rank of the first among landscape-painters. He painted for his study a landscape, compounded of many views, taken in the Villa Madama, with an infinite variety of trees, which he kept as a store of natural objects. He refused to sell it, even when Clement IX. offered to cover it with pieces of gold. This picture, and another of Esther and Ahasuerus, he is said to have mentioned as his best productions. He used to make drawings of his pictures in a book, in order to prevent their being pirated. He left six of these registers, which he called his 'Libri di Verita;' one of them, well known by Earlom's engravings, is in the possession of the Duke of Devonshire.

His colouring is rich, powerful, and brilliant; his tints are varied as in nature itself. His aërial perspective is perfect; the fore-ground stands out with the force and brightness of an Italian sunshine; the distance recedes clear and wide, till the blue hills and blue sky meet in harmonious contrast, or melt into the rich, warm, dewy atmosphere of Rome. His architecture is light and fanciful, and often charmingly mixed with foliage, which is graceful and moving. The water ripples and undulates in the tremulous light, or lies calm and glassy, with deepening shadows. His composition is a singular union of freedom and symmetry. If his landscapes have a fault, it is that the graceful is too invariably selected; a trifle of roughness, or irregularity, would add to the interest of the picture. His figures are very poor, which he freely admitted, saying he sold the landscape and gave away the figures, a trait of modesty which seems in accordance with his mild and amiable character. He left his property to two nephews and a niece, his only surviving relations.

CLAUDE, JEAN, born in 1619, at Sauvetat, near Agen, was the son of a Protestant clergyman, and was himself brought up to the church. He distinguished himself in controversial learning, and was appointed professor of theology in the Protestant college of Nismes, which place he filled for eight years. At the end of this time the vexations of the government authorities obliging him to abandon his chair, he went to Paris, where he was soon after appointed to the church of Charenton in 1666. In this situation he showed himself by his writings one of the ablest champions of the Protestant doctrines, an antagonist not unworthy of Bossuet, Arnauld, Nicole, and other distinguished Catholic divines. In 1671 he published his 'Réponse au Traité de la Perpétuité de la Foi sur l'Eucharistie,' 2 vols., 8vo. [ARNAULD.] In 1673 appeared his 'Défense de la Réformation, ou Réponse aux Préjugés légitimes de Nicole.' In 1681 Claude had a controversial conference with Bossuet, after which he published 'Réponse à la Conférence de Bossuet.' The conference as usual led to no approximation between the contending parties. In 1685 the Revocation of the Edit de Nantes by Louis XIV. obliged Claude to seek refuge in Holland, where he was well received on account both of his talents and his personal character, and the Prince of Orange granted him a pension. He died not long after in 1687, much regretted by his co-religionists as one of their ablest and most estimable advocates. His 'Plaintes des Protestans cruellement opprimés dans le Royaume de France' was published after his death, as well as other posthumous works, chiefly on theological and controversial subjects. He left also some sermons. His style though simple was vigorous, being sustained by great logical skill and much erudition. Devèze wrote a biography of Claude, Amsterdam, 1687. His grandson, Jean Jacques Claude, was one of the earliest pastors of the French Protestant church in Threadneedle Street, London, and died in 1712.

CLAUDE, ST., a town in France, in the department of Jura, on the bank of a small stream called the Bienne, which flows into the Ain, a feeder of the Rhône. It is 240 miles S.E. of Paris in a direct line, in 46° 23′ N. lat., and 5° 32 E. long.

This town owes its origin to the retirement of the Saints Romain and Lupicin (the latter bishop of Vesontio, or Besançon) to the deserts of Mount Jura, in the fifth century. The sanctity of these holy men, who were brethren, drew around them a number of kindred minds, and three monasteries with other establishments arose in the neighbourhood of their retreat. In the eighth century St. Claude, archbishop of Besançon, came to end his days in one of these monasteries, which afterwards took its name from him, and thus the town acquired its present designation.

The abbey of St. Claude was of the Benedictine order, and the monks were obliged to make proof of noble descent before they could obtain admission into the establishment. The community possessed immense wealth: it is said by La Vallée (*Voyage dans les Départements*)—no very trustworthy authority, indeed—to have had a revenue of 100,000 *écus*, or about 12,500*l.* The monks, before the suppression of the establishment, had ceased to live in common; each had his distinct portion of the revenue. This monastic institution was the last in France which held its vassals in a state of villainage, and whoever was resident a year in their domains became their serf. It was not until the reign of Louis XVI. that the feudal powers of these ecclesiastics were entirely suppressed. The abbot was lord of the town. In 1742 this abbey was secularized, and erected into a bishopric; the bishop and chapter succeeding to the rights and many of the usages of the abbot and monks.

St. Claude is built at the foot of a mountain, one of those amid which it is placed, and at the confluence of the torrent Ison with the Bienne. It is surrounded by walls, which include a part of the adjacent mountain, but cannot be considered as fortified. The town was destroyed by fire in 1799; but a sum of 750,000 francs (about 30,000*l.*) granted by the consular government, and numerous collections made all over France, enabled the inhabitants to rebuild it on a much more regular plan.

The inhabitants amounted, in 1832, to 4170 for the town, or 5222 for the whole commune. They are busily engaged in the manufacture of toys and trinkets in tortoiseshell, horn, ivory, bone, box and other woods: beads, needles, pins, musical snuff-boxes, and other musical instruments, and nails, are among the articles made here. The traders of this town have direct commercial intercourse with foreigners. Several have establishments at Beaucaire; they import goods from Germany and England. There is a good hospital, a large public school, and several other useful institutions. Beautiful marble is quarried in the neighbourhood, and pretty good ochre is procured. Peat for fuel is also obtained.

The arrondissement of St. Claude contained, in 1832, 52,433 inhabitants, who are engaged in making turnery and other wooden wares, spinning cotton yarn, weaving crape, drawing iron wire, making wooden and metal clocks, enamel watch-faces, roasting-jacks, spectacle-frames, and imitation gems.

The bishopric of St. Claude comprehends the department of Jura, containing 312,504 inhabitants. The bishop is a suffragan of the Archbishop of Lyon and Vienne.

CLAUDIA'NUS (CLAU'DIUS) was born at Alexandria, in Egypt, A.C. 365 (*Epist.* i., 20, v. 3). Though of a family originally Roman, his education was Greek; and he appears to have written first in the Greek language. His work on the 'Antiquities of Tarsus' is lost. Of his early life little is known. His first Latin verses were written during the consulship of Probinus, A.C. 395. (*Epist.* iv., vv. 13, 14). In this year he became a dependent of the regent Stilicho, guardian of the two minors, Arcadius and Honorius; and in his poems he sometimes alludes to his soldier's life. (*Prol. Carm. de Consulatu* Mallii Theodori, vv. 5, 6.) Whether from a hope of being immortalized in verse, or from some other motive, Stilicho warmly befriended the poet; nor were the favours of his beautiful wife Serena acknowledged less gratefully than those of the minister himself. (*De Laudibus* Stilichonis, lib. iii.; *Laus Serenæ Reginæ.*) Claudian seems to have enjoyed all the splendour and luxuries which the high station of Stilicho afforded; and he either purchased or requited those indulgences by lavishing indiscriminate eulogies on his patrons and bringing infamy and ridicule on their enemies. The praises of Stilicho are the constant subject on which he delights to dwell, even when he does not directly mention his name; and where the materials of regular history are wanting, his poems form a valuable clue to the connexion and character of events.

The most important favour for which he was indebted to Serena appears to have been her assisting him to obtain a very wealthy bride (*Epist.* ii.). The nuptials were celebrated at Alexandria (*Epist.* ii., vv. 55, &c.); and it seems probable that Claudian and his wife soon after came to Italy. After the war with Gildo he was honoured with a bronze statue (*Præf. in Bellum Geticum*, vv. 5, 6), erected in the forum of Trajan, an honour which, as Gibbon (ch. 30) observes, he acknowledged as a man who deserved it: the inscription which was cut on the statue is still extant (Orelli, *Corpus Inscript.*, vol. i., p. 259).

The death of Stilicho (A. D. 408) was soon followed by the ruin of his favourite. Hadrian, the successor of Stilicho, had formerly been the subject of a satirical epigram (*Epigr.* 25, in some editions 30,) of Claudian, and he now began to watch for a favourable opportunity of revenge. The particulars of his death are not known; but it seems clear that his attempts to conciliate Hadrian were ineffectual, and that he finally fell a victim to his resentment.

It has been a subject of dispute, whether Claudian was or was not a convert to Christianity. The poems which have given rise to the supposition that he was, have been attributed to him erroneously; they are clearly the work of another writer.

Claudian's poetical merits, though not of the highest order, are considerable. He does not excel in the chastised and severe beauties of the older poets whom he aspired to imitate, nor is he remarkable for great invention or a lofty imagination; but in what may be called the picturesque style he is surpassed by none: he brings out the smallest details of a scene into a vivid and correct form, amplified and ornamented with all the graces of diction. The most prosaic topic in his hands is invested with the charms of poetry. An elegant and harmonious versification always delights his reader. 'In the decline of arts and of empire, a native of Egypt, who had received the education of a Greek, assumed in a mature age the familiar use and absolute command of the Latin language, soared above the heads of his feeble contemporaries, and placed himself, after an interval of 300 years, among the poets of antient Rome.' (Gibbon, *Decline and Fall*, chap. 30.)

Claudian's principal poems are, 3 books 'De Raptu Proserpinæ;' 3 books 'De Laudibus Stilichonis;' 2 books 'In Rufinum;' 2 books 'In Eutropium;' 'De Bello Getico;' 'De Bello Gildonico,' &c. The best editions are those of Gesner and Burmann. Claudian is included in Weber's 'Corpus Poetarum Latinorum.' Frankfort, 1833.

CLA'UDIUS NERO, the son of Drusus Nero, the brother of Tiberius, and of Antonia Minor, the daughter of M. Antonius the Triumvir, by Octavia, the sister of Augustus, was born at Lyon B. C. 10. [AUGUSTUS.] In his youth he was sickly, weak, and timid, which made his mother say that he was but the half-finished sketch of a man. Augustus, in compassion, used to call him *misellus*, little wretch. He was left to the company of the women and the freedmen of the palace, and little notice was taken of him under Augustus and Tiberius. He lived in privacy, and appears to have applied himself with perseverance to study. He became a proficient in Greek and Latin, and wrote, with the assistance of Sulpicius Flavius, a history of Rome, in 43 books, which is lost. He suggested the addition of three new letters to the Roman alphabet, and he enforced the use of them during his reign, after which they fell into disuse, but still appeared in the time of Tacitus in the old inscriptions (*Annal.* xi., 14). He also applied himself with much perseverance to the study and practice of oratory, and Tacitus has transmitted to us a favourable specimen in a speech which he delivered before the senate when emperor, in favour of the Gauls, who were asking to be admitted to the rights of Roman citizens. (*Annal.* xi., 24.)

When Caligula, who was the nephew of Claudius, became emperor, he took his uncle as his colleague in the consulship, A. D. 37. After the expiration of his consulship Claudius again withdrew into privacy, from which he was dragged by some mutinous soldiers, who were overrunning the imperial palace after the death of Caligula, and who discovered Claudius concealed behind a tapestry, and trembling from fear. They raised him on their shoulders, and carried him to the camp, where he was proclaimed emperor by the troops, A. D. 41, against the wishes of the senate and of many of the citizens, who were for restoring the republic.

This was the first example of that baneful practice, which the soldiers so often repeated, of disposing of the imperial crown. Claudius, who was then 50 years of age, began his reign by acts of justice and of mercy; he recalled exiles, restored to the rightful owners much property which had been confiscated under Tiberius and Caligula, rejected the honours and titles which the flattery of courtiers would have bestowed upon him, embellished Rome, formed an aqueduct for a fresh supply of water, which still bears his name, constructed a harbour at the mouth of the Tiber, and began the emissary of the lake Fucinus. [CELANO.]

He also went over to Britain, which country he first permanently occupied, at least in part, by his generals Plautius and Vespasianus, and afterwards by Ostorius. [BRITANNIA.] Caractacus, who was brought prisoner before him at Rome, experienced the imperial clemency. Claudius afterwards fell into a state of apathy and imbecility, being entirely governed by his profligate wife Messalina and the freedmen of the palace who were leagued with her. They took advantage of his excessive timidity and credulity to make him sign the death-warrants of numerous senators and knights, whom they represented as conspirators, and whose property was confiscated for their benefit. Messalina openly abandoned herself to the most shameless licentiousness, and no one dared to check her, or remonstrate with the emperor on her conduct, for fear of incurring her deadly revenge. She carried her effrontery at last so far as publicly to marry Caius Silius, one of the handsomest men of Rome, while Claudius was absent at Ostia. The emperor, who was roused from his torpor by the report of this scandal, gave orders that Messalina should be put to death. Soon afterwards he married, A.D. 50, his own niece, Agrippina the younger, the widow of Domitius Aenobarbus, and mother of L. Domitius. Agrippina easily prevailed on the weak Claudius to adopt her son Domitius, who assumed his stepfather's name of Nero, by which he was afterwards known as emperor, and to give him in marriage his daughter Octavia. Agrippina having thus paved the way for the succession of her own son to the throne, to the prejudice of Britannicus, the son of Claudius by Messalina, completed her object by poisoning her husband at Sinuessa, where he had gone for the benefit of his health. Claudius died A. D. 54, in his sixty-fourth year, after being in possession of the sovereign power for thirteen years and nine months. His funeral was celebrated with great pomp, and he was numbered among the gods, but his will was not read in public, in order to avoid exciting disturbances among the people on account of the preference given to Nero over Britannicus. (Tacitus, *Ann.* xii. 69; Suetonius, *Claudius*; Dion.)

CLAU'DIUS, or CLODIUS, ALBI'NUS, a native of Adrumetum, in Africa, served with distinction under Marcus Aurelius and Commodus in various parts of the empire; in Asia, in Gaul, in Germany against the Frisians, and lastly in Britain. When Avidius Cassius, governor of Syria, revolted against M. Aurelius, Albinus, who commanded the troops in Bithynia, checked the revolt which was beginning to spread among his soldiers. In consequence of this service he was raised to the consulate, together with Pompeianus, the emperor's son-in-law, A. D. 176. When Septimius Severus became suspected of aspiring to the empire, Commodus, with the view of strengthening himself, offered to Albinus, who was then commanding in Britain, where he had succeeded Pertinax, the title of Cæsar, which Albinus declined. After the assassination of Commodus and of his short-lived successor Pertinax, Didius Julianus being made emperor by the prætorian guards of Rome, who now assumed the right of disposing of the empire to the highest bidder, three commanders of the legions abroad, Albinus in Britain, Severus in Illyricum, and Pescennius Niger in Syria, stood forth to dispute this right by the corresponding argument of the will of their own soldiers. Severus, who was the nearest to Rome, marched upon the city, upon which the senate proclaimed him emperor, and the prætorians made way for him by assassinating the unfortunate Julianus. Severus while on his march had written to Albinus, proclaiming him Cæsar, and adopting him as his successor. This time Albinus accepted the title, which he assumed publicly at the head of his legions; and the senate confirmed it, after the accession of Severus. But the new emperor having first overthrown his competitor Pescennius Niger, resolved to rid himself also of his dubious associate Albinus; who, having discovered his intentions in time, passed over into Gaul, where he was proclaimed emperor, and strengthened himself by fresh recruits. Severus hurried from the east against this new enemy, and after several partial engagements a great battle was fought near Lyon, in February, A.D. 197, in which Severus was worsted at first and wounded, according to Spartianus, but succeeded in rallying his cavalry, with which he gained the victory. The soldiers of Albinus having taken refuge within Lyon, that city was invested, stormed, and burnt, by the troops of Severus. Albinus, according to Dion, killed himself, and his body was carried to Severus, who had the head cut off and taken to Rome, and the body thrown into the Rhone. Severus, with his characteristic inhumanity, put to death the wife and children of Albinus, and ordered a general proscription of all his friends, who were numerous in Gaul and in Spain, and even at Rome. Albinus appears to have been a man of considerable talents and information. He was a distinguished commander, and had many partisans among the senators, but was harsh and even cruel in his military discipline: and is said by Capitolinus to have been an enormous glutton. (Herodian, Dion, and Spartianus; and Julius Capitolinus in the *Historia Augusta.*)

CLAUDIUS, MARCUS AURELIUS, surnamed GOTHICUS, was born in Illyricum A. D. 214, served in the army as tribune under Decius, was afterwards governor of his native province under Valerianus, and after the death of Gallienus in 268, near Milan, was proclaimed emperor by the army. The choice was immediately approved by the Senate. Claudius began his reign by defeating the usurper Aureolus, who had revolted against Gallienus, and had taken possession of Milan. Aureolus was killed in the battle. Claudius afterwards marched against the Germans, who had entered Italy, and defeated them on the banks of the Benacus (Lake of Garda.) On arriving at Rome, he was received with great honours, and applied himself to reform many of the abuses which existed in the administration of the empire. In the following year he marched against the Goths, or Scythians, who had invaded the provinces of Mœsia, defeated them with great slaughter, and made a vast number of prisoners, whom he distributed over various provinces as labourers. In consequence of this victory, he assumed the name of Gothicus. In the year after (A. D. 270) he died at Sirmium, in Pannonia, of a contagious disease which had spread in his army, after a short reign of little more than two years, during which he exhibited virtues and abilities that entitle him to be numbered among the best emperors of Rome. The Senate named his brother Quintilius his successor, but the army proclaimed Aurelianus, upon which Quintilius was killed, or killed himself according to others. (Trebellius Pollio *in Historia Augusta.*)

[Coin of Claudius Gothicus.]
British Museum. Actual size. Bronze. 125 grains.

CLAUSENBURG (Kolos), a county in the west of Transylvania, in that part of it called the 'land of the Magyars,' which is one of the four divisions of the principality. It has an area of 1861 square miles, and contains 100,000 inhabitants, who are chiefly employed in rearing cattle, in agriculture, mining, and a few manufactures, and trade. It has one royal free town, five market-towns, 202 villages, and thirty-five prædia, or privileged settlements, and is divided into six 'processes.' The chief rivers are the Szamós and Körös. It is very mountainous: the most elevated points are Varatik, Trugassa, Yladiassa, Balamirassa, and Kalota. It abounds in horses, oxen, sheep, goats, and swine; also in honey and corn, and produces salt, gold, iron, and some wood.

CLAUSENBURG (Klush, Kolosvár), a royal free town and capital of the principality of Transylvania. The town was founded by the Romans, who gave it the name of Claudia, whence its Latin designation Claudiopolis. In 1178 the new town was enlarged by a colony of Saxons, who from its locality called it Clausenburg, from the old word Klause, which signifies a mountain defile. The citadel, which lies on a hill, was not erected till 1721, since which date commodious barracks have been made in it. Owing to its flourishing trade and manufactures it was formerly one of the principal towns of the country. Settlers flocked to it from all parts, till the place becoming too confined, the new-comers were obliged to take up their abode in the neighbouring villages, which thus became the property of the town. Clausenburg is situated on the river Szamos, in the midst of a romantic valley, surrounded with mountains, and studded with fields, gardens, and vineyards. It is surrounded with lofty walls and towers, and is divided into the inner town and six suburbs; the former consists of the Ovar (Altburg), or old town, and Ujvas, or new town, and though of small extent has a very pleasing appearance. It has some handsome streets and houses, and a large market-place, 500 paces long and 360 broad. There are also several churches, the most striking of which is the Roman Catholic cathedral, erected in pursuance of a vow of King Sigismund in 1399; it is 94 paces long and 34 broad, and contains some fine monuments. Of the other churches, five are Roman Catholic, several Protestant, and one Græco-Catholic. The members of the Oriental Confession have their distinct places of worship.

Clausenburg contains an academical lyceum, having 185 students, with a public library attached; a Roman Catholic gymnasium, with 270 pupils; a reformed college, with 550 pupils; a Græco-Catholic, with 306 pupils; a Roman Catholic seminary; a seminary for the young nobility; a Franciscan convent; normal schools, with above 300 scholars; a house of industry for poor men and women, established by an association of ladies; an orphan asylum, two hospitals, and various other charitable institutions; a Casino, containing the assembly rooms, the profits of which are devoted to purposes of charity; a large national theatre, and several public gardens around the town, one of which is called the 'People's Gardens.' Among the other buildings is the old castle, which is now in ruins, the town-hall in the market-place, and numerous palaces belonging to the higher nobility.

Clausenburg is the seat of the government of Transylvania, of the consistory of the Protestant and Græco-Catholic communions, the board of education, and other public departments. Being a Fiskal-gut or Taxal-Ort (that is, a place having its own independent jurisdiction), it is not included in the jurisdiction of the province, but all its civil and other affairs are conducted by its own judges and magistrates. It contains 20,000 inhabitants, who are chiefly Hungarians, intermixed with Saxons, Armenians, Greeks, and Jews. There are few mechanics, and it has little trade. The manufactures, which are inconsiderable, are chiefly woollens, earthenware, and paper. It is the birth-place of the celebrated Matthias Corvinus, king of Hungary. 46° 53′ N. lat., 23° 48′ E. long.

CLAUSI'LIA. [LIMACINEA.]

CLAUSTHAL, in the Hanoverian Landrostei, or Bailiwick of the Harz, the largest and most important of the mining towns of the Harz, is an open place built upon two naked eminences, and separated from Zellerfeld (a town of 4000 souls) by the rivulet called Zellerbach. It is the seat of administration for the mining districts of Hanover, and lies at an elevation of 1170 feet above the sea, and about 50 miles S.E. of Hanover. The adjacent parts abound in ores. The streets are straight and broad, and planted in general with chestnuts and lime-trees, but are very badly paved. It contains two churches, an orphan asylum, a mint, in which about 700 ducats and 400,000 dollars are annually coined, and public offices, a mining academy, to which a seminary for teaching forest economy is attached, with collections in mineralogy, &c., a gymnasium, manufactories of iron ware, yarns, woollens, camlets, &c., and several elementary schools. In the immediate vicinity are the richest mines of the Upper Harz: their chief products are annually about 160,000 ounces of silver, 4 tons of copper, and 2400 tons of lead and litharge: they employ upwards of 2000 workmen. The number of houses in Clausthal is about 850, and of inhabitants about 8900. 51° 48′ N. lat., 10° 20′ E. long.

CLAVAGELLA (Zoology), a genus of testaceous acephalous animals established by Lamarck in the fifth volume of the 'Histoire Naturelle des Animaux sans Vertèbres,' published in 1818, and arranged by him under his Tubicolées, between *Aspergillum* and *Fistulana*. He described four species, all fossil, referring at the same time to the 'Annales du Muséum,' where he had figured the first of them under the name of *Fistulana echinata*. Lamarck thus defines the genus:—'A tubular, shelly sheath, attenuated and open anteriorly, terminated posteriorly in an ovate subcompressed club beset with tubular spines; the club presenting on one side the one valve fixed in its wall or substance, while the other valve remains free in the tube.'

The genus was only known in a fossil state to conchologists, when Mr. George Sowerby, to whom students in this department of zoology are much indebted, observed in the British Museum a recent specimen, which he at first thought might be an *Aspergillum*, inclosed in a mass of stone. On application to Mr. Children, that gentleman allowed Mr. Sowerby to examine it more closely, and on scraping away some of the investing stone, the latter found *Clavagella aperta*, the first recorded recent species, and figured and described it in his 'Genera of Recent and Fossil Shells.'. The same naturalist, on the return of Mr. Samuel Stutchbury from his voyage to some of the Australian and Polynesian Islands, described and figured (1827) a second species, *Clavagella Australis*, three specimens of which were with difficulty obtained by Mr. Stutchbury at North Harbour, Port Jackson, in a siliceous grit like that of the coal-measures, where their presence was betrayed just beneath low-water mark, by their forcible ejection of the water from the aperture of their tubes: the specimen of *Clavagella Australis* figured by Mr. Sowerby is also in the British Museum. In 1829 Mr. Henry Stutchbury, in arranging the collection of Mr. Isaac Lyon Goldsmid, suspected the presence of a *Clavagella* in a mass of *Astræopora*, and, on fracturing the specimen, laid open two individuals of another species (*Clavagella elongata*, Brod.). According to Cuvier, and a notice in the 'Annales des Sciences Naturelles' (tome xvii., p. 78), M. Audouin (1829) described a recent species, and M. Rang, in his 'Manuel des Mollusques' (1829), mentions another, apparently *Clavagella rapa*.

Still the animal remained unknown; when, on the return of Mr. Cuming from his first voyage, that zealous collector produced another specimen which fortunately included the soft parts. A fragment of calcareous grit was dredged up by Mr. Cuming from a depth of eleven fathoms, at the island of Muerte, in the bay of Guayaquil, and in this was the greater portion of the chamber and tube, both valves, and the animal of *Clavagella lata*, Brod. Mr. Broderip, who has described this and two other recent species in the first volume of the 'Transactions of the Zoological Society' (p. 261), says, that a close examination of the recent species has convinced him that though one valve is always fixed or imbedded in the chamber, and soldered, as it were, to the tube, so as to make one surface with it, the tube is not necessarily continued into a complete testaceous clavate shape. In Mr. Goldsmid's best and largest specimen, the fixed valve was imbedded in the coral, and though continued on to the tube or siphonic sheath, was surrounded by the wall of the coral chamber at its anterior extremity. In the other specimen the fixed valve was also continued on to the tube. In the first-mentioned specimen of *Clavagella elongata*, at the anterior or greater end of the ovate chamber, an insulated or shelly plate had been secreted with tubular perforations; that part of the chamber having afforded (apparently at a former period) the best communication with the ambient fluid: but a calcareous deposit having almost entirely cut off that communication, the animal seemed to have been compelled to secrete a second shelly plate towards the anterior ventral edge of the fixed valve, where the perforation of some other shell (a *Lithodomus* probably) secured the necessary influx of water. Nor is this the only instance of the secretion of a second tubular plate which has fallen under Mr. Broderip's notice. In the last-mentioned, or smaller specimen, the perforated shelly plate joins the anterior ventral edge of the fixed valve laterally, that point of the chamber being evidently the most practicable for communicating with the water by means of the tubules: the rest of the anterior edge of the fixed valve is surrounded by the coral wall. In Mr. Cuming's specimen the fixed valve is continued on to the tube. The anterior edge of this valve is surrounded by the naked wall of the chamber, and the greater end of the chamber, or that part of it which is opposite to this anterior edge, being impracticable, from its thickness, as a water communication (with a small exception, which, not improbably, had ceased to be available), the animal had been driven to secrete the perforated shelly plates not far from the throat of the tube on either side, where the chambers of *Petricolæ* or *Lithodomi* opened a passage to the surrounding water.

Organization.

Position, &c. of the animal.—Mr. Owen made his observations in his excellent paper on the anatomy of *Clavagella* (*Zool. Trans.*, vol. i. p. 269) from the specimen of *Clavagella lata* above alluded to, the soft parts of which were placed in spirit by Mr. Cuming soon after its capture. He found the following to be the relative position of the animal:—The *mouth* turned towards the closed end of the chamber, which is consequently the anterior part. The *heart* and *rectum* near the side where the valves are connected by the ligament, or the dorsal part. The visceral mass projecting towards the opposite or neutral side. The *siphon* extending into the commencement of the calcareous tube, which leads out of the anal or posterior part of the chamber. The *fixed valve*, which covers the rough surface of the porous rock or coral, like the tiling of a chamber-floor, and affords a smooth polished surface for the support and attachment of the animal, is the *left valve:* the *right valve* remains free, or is connected only to the soft parts and cardinal ligament, in order to assist in the excavating and respiratory actions.

Shell.—The shelly substance of the fixed valve passes without interruption into that of the tube; a slight ridge circumscribing the entry of the tube into the chamber indicating the line of separation, unless the extent of the valve be limited to that of the internal nacreous deposition. The *tube* of an oval form, 7 lines by 5 in diameter. The calcareous walls $\frac{1}{20}$th of an inch in thickness at the outlet, and about $\frac{1}{30}$th at the opposite extremity. The *free valve* unequally triangular, with the angles rounded off, about the thickness of a sixpence, moderately concave towards the soft parts, and striated only in the direction of the layers of increment on the outer surface, as in most of the *Pyloridean* Bivalves of M. de Blainville. The layers gradually increase towards the dorsal edge for a little more than one half of the valve, beyond which the layers continue of almost equal breadth. 'This growth of the valve,' adds Mr. Owen, 'corresponds to the direction in which the chamber is enlarged, which is principally on the dorsal, dextral, and anterior sides: now this is the mode of enlargement best adapted for the full development of the ovary; so that it would seem that the *Clavagella* continues for a time to work its way into the rock without material increase of size, leaving behind it a calcareous tube, which marks its track; after which it becomes stationary, and limits its operations to enlarging its chamber to the extent necessary for the accomplishment of the great object of its existence.'

Mantle, and Muscular System as ancillary principally to Respiration.—*Mantle* enveloping the body like a shut sac, but perforated for the siphon and foot, the opening for the latter being reduced to a small slit. M. Rüppell observed an analogous orifice in the corresponding part in *Aspergillum*, viz. that which is next the sunken sieve-like extremity of the tube, and by which he supposes the water necessary for respiration to be received when the retreating tide leaves exposed the expanded siphonic extremity. Mr. Owen is of opinion that this cannot be its use in those species of *Clavagella* which exist at depths too great to allow of their being ever left with the siphonic aperture out of water; but that it must serve to keep up a communication with the neighbouring cavities of the rock, by means of the calcareous tubules, the formation of which is determined by the proximity of these cavities. When therefore the *Clavagella*, by a sudden contraction of its adductor muscles, has forcibly expelled the branchial currents from the siphon, as was observed by Mr. Stutchbury, the space between the free valve and the walls of the chamber would be simultaneously filled, either by water rushing in through the tubules, or forced out from the branchial cavity through the small anterior orifice of the mantle. To assist this operation there is a proportional development of the muscular system, which is remarkably powerful. The impression of the great or posterior adductor is carried two lines beneath the surface of the chamber posteriorly, but gradually rises to the level of the valve. The impression of the smaller anterior adductor is more faint, and is continued into the sinuous pallial impression, which follows the contour of the anterior margin of the valve at about two lines distance from it. In the free valve the last two muscular impressions are separate. The outer dermoid layer of the mantle is extremely thin, and, where it does not line the valves, is mottled with minute dark spots, less numerous than those on the skin of *Cephalopods*, and presenting, under the microscope, a glandular appearance. The muscular layer, after forming the *siphon* and its retractors, is confined to the anterior part of the mantle, where it swells into a thick convex mass of interlaced and chiefly transverse fibres, and forming, Mr. Owen supposes, one of the principal instruments in the work of excavation. No fibres could be detected in other parts of the mantle; nor, observes Mr. Owen, could any be expected in a mantle which had no lobes to be retracted. The *siphon*, in the contracted state, formed a slightly-compressed cylindrical tube, half an inch in length, and the same in the long diameter, traversed longitudinally by the branchial and anal canals, separated from each other by a muscular septum, extending to the end of the siphon, beyond which the two tubes do not separately extend outwards, agreeing in this respect with *Gastrochæna* and *Aspergillum*. Muscular walls of the siphon two lines in thickness; the septum separating the branchial and anal canals one line; diameter of each canal about one line; inner extremity both of the anal and respiratory tube provided with a valvular fold: terminations beset with short *papillæ*. The retractor muscles attach the siphon to the posterior adductor on one side, and to the anterior extremity of the oval mass of muscular fibres above mentioned on the other, leaving an intermediate space on both sides the body, which exposes part of the gills and labial tentacles. The muscular mass which bounds the anterior part of the animal's body is oval, one inch three lines long, eight lines broad, and varying in thickness from two to three lines: it is smooth and convex externally, and hollowed out within to lodge the *viscera* at the base of the foot, for the passage of which it leaves the small orifice above mentioned. The margins attached to the valves are more or less irregular; that affixed to the loose valve is the broadest, being at the ventral extremity three lines in length. Mr. Owen thinks that it may here be regarded as a third adductor: posteriorly it is continued into the small adductor muscle.

Branchiæ and Circulating System.—The gills have the same laminated structure as that observed in other bivalves they are broad and short, corresponding to the form of the animal, and the *laminæ*, not thin compressed layers, but broad and projecting but little from the sides of the visceral mass, are arranged in three layers instead of two, on either side of the foot. They take their origin between the labial appendages, at the side of the mouth, extending backwards towards the inner orifice of the respiratory tube, where they meet, join, and terminate in a point which is unattached for about one-eighteenth part of the entire gill. The branchial veins are continued from the concave side of the gills, a few lines behind their anterior extremities: these veins are joined by others from the muscular part of the mantle, and then terminate in two large membranous dark-coloured auricles. These communicate with a fusiform ventricle, single externally, but divided within, by a longitudinal *septum*, into two compartments, corresponding to the auricles; which compartments communicate together at the *apex* of the ventricle, from which the principal artery is continued. (Owen.)

Digestive System, accordant with the structure of the same part in the other acephalous mollusks. The mouth, a transverse slit, without masticatory or salivary organs, is bounded by the upper and lower labial processes which are continued in the form of two transversely striated pointed tentacles on either side: these prehensile, sensitive, and, according to Mr. Owen, probably respiratory organs measure, each, six lines in length, and about one and a half line in breadth. The œsophagus, after a course of two lines, dilates into a stomach, the sides of which are perforated by the large hepatic ducts. The intestine, after a course of eight lines, forms a small cæcum about one line in length: this, Mr. Owen observes, may be taken for a *pancreas;* or perhaps is the analogue of the blind sac containing the peculiar amber-coloured style which projects into the pyloric end of the stomach of some *Bivalves*. The little *cæcum*, in the specimen dissected, contained the same brown granular material as distended the rest of the canal. The intestine, after making three close turns upon itself in the mass of *ova* and hepatic follicles at the base of the foot, passes in immediate contact with, but not through, the heart, and then below the posterior adductor, to opposite the posterior office of the anal tube. The exterior of the intestine has an irregular honey-combed appearance, from the close adhesion to it of the capsules of the *ova*. The *liver* has the same divided follicular structure and green colour as in the other *Bivalves*. (Owen.)

Nervous System.—A large and conspicuous *ganglion* is situated at the posterior part of the base of the foot, just above the orifice of the anal tube. Two nervous cords extend from this *ganglion*, on either side the foot to the mouth other branches radiate in the opposite direction to the siphonic and adductor muscles. (Owen.)

Generative System.—The ovary, of a grey colour, forms a mass at the dorsal aspect of the body above the great adductor muscle, and extending ventrad on either side the *œsophagus* and stomach to the opposite end of the base of the foot. All this mass of intestinal folds, hepatic follicles, and *ova* was covered by a thin membrane. The little muscular process or foot which passes through the anterior slit of the mantle is but four lines long, and half a line in breadth: its possible use may be to apply a solvent to the rock in which the chamber is excavated. (Owen.)

Habits.—Mr. Broderip observes that we are left to conjecture the causes which operate to determine the animal in the choice of its abode, if indeed it can be called choice, for most probably *Clavagella* is the creature of circumstances, and if, soon after its exclusion from the parent (when Mr. Broderip supposes it to be furnished with its two valves only, and to float free, with, perhaps, some voluntary impulse), it arrives at the vacant hole of some small *Petricola*, *Lithodomus*, or other perforating *Testacean* which suits it, one valve soon becomes attached to the wall of the hole, and then the animal proceeds to secrete the siphonic sheath or tube, to enlarge the chamber according to its necessities, and to form the shelly, perforated, tubular plate which is to give admission to the water at the practicable part of the chamber. How the excavation is carried on is also doubtful. The chambers of the individuals of *Clavagella Australis*, described by Mr. Broderip, were formed in a siliceous grit, those of *Clav. elongata* in an *Astræopora*, that of *Clav. lata* in a calcareous grit, and those of *Clav. Melitensis* in an argillo-calcareous tufa. 'If,' says the author last mentioned, 'the excavation be the work of a solvent secretion, it must be a solvent of extensive power. The situation of the glands, detected by my friend Mr. Owen, leads me to think that they minister in some way to this operation; and I do not see how the anterior or greater end of the chamber can be operated on by mere mechanical attrition with such parts as must have been contiguous to it. It has been objected that any solvent which would act on a calcareous rock would equally act on the calcareous shell of the animal; but there is, perhaps, more of point than of strength in this objection. Without laying too much stress on that law of nature by which chemical and vital forces are placed in a state of hostility,* and which may or may not be applicable to such a substance as shell, the gland for the secretion of the supposed solvent, as well as the organ for applying it, may be so placed as that the solvent shall only come in contact with the inorganic or dead substance to be acted on without touching the shell. Again, it has been asked, what solvent would act equally on a calcareous and on a siliceous substance? To this it may be answered, first, that it is not pretended that the nature of the supposed solvent is known; secondly, that, in siliceous grits, there is more or less calcareous matter by which the mass is held together, and that the solution of the calcareous particles would be followed by the disintegration of the stone. * * * * One observation, arising from the various depths at which the recent species have been found, will not, perhaps, be deemed irrelevant. *Clav. Australis* was so near the surface at low water, that it was detected by its ejection of the fluid; *Clav. elongata*, from the nature of the coral in which

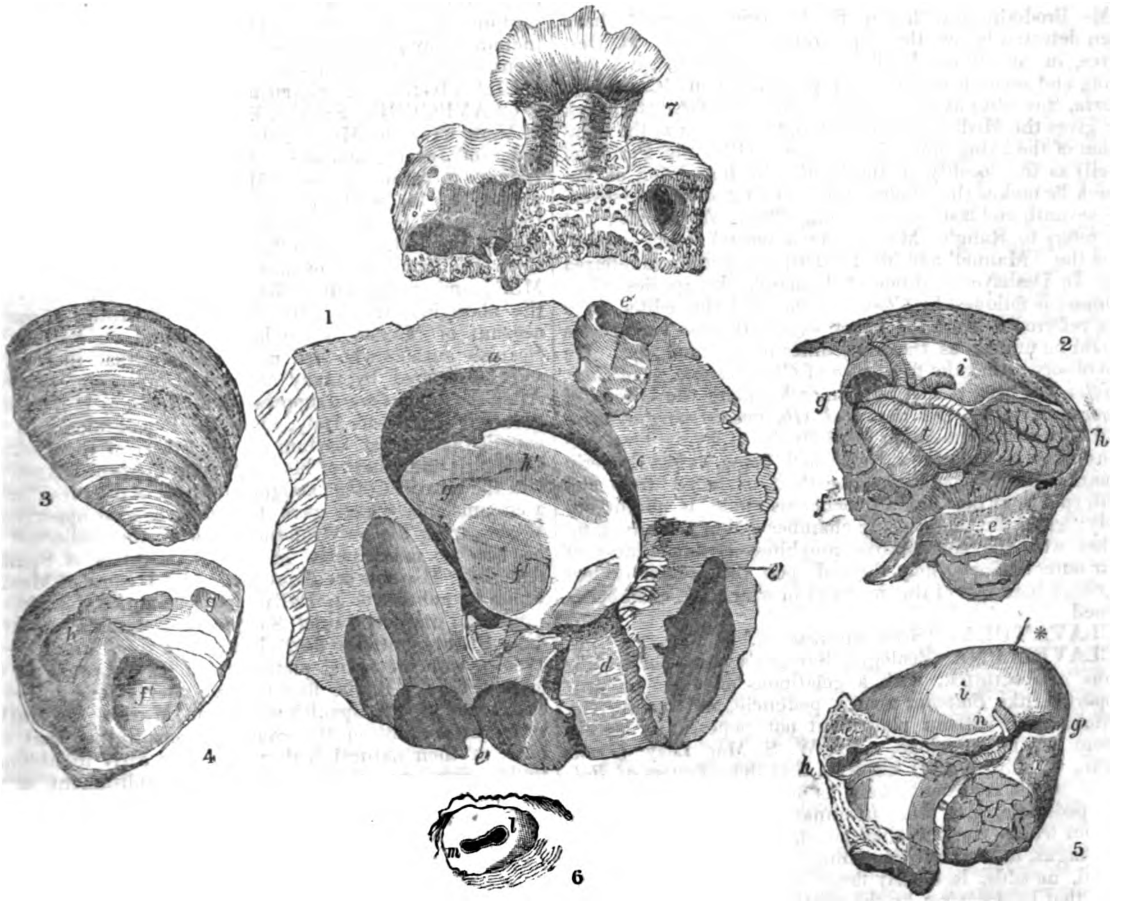

Fig. 1, part of calc. grit rock containing the fixed valve and part of the tube of *Clavagella lata*; *fig.* 3, external view of the right or free valve; *fig.* 4, internal view of same, showing the muscular impressions corresponding with those of the left or fixed valve; *fig.* 2, soft parts of *Cl. lata* seen from the right side the dermal layer of the mantle, *e*, being removed; *fig.* 5, the same seen from the left side, or that which is in contact with the fixed valve. The extremities of the left labial appendages only are exposed, no part of the gill being protruded. A bristle is placed in the opening of the mantle; *a*, anterior wall of the chamber; *b*, dorsal wall; the letter placed on the hinge of the fixed valve; *c*, ventral wall; *d*, posterior or siphonic outlet; *e*, tubular communications with a neighbouring cavity, here sent off from the posterior part of the mantle; *e'*, *e'*, calcareous tubes secreted by the above processes and extending into the cavities contiguous to the throat of the tube; *e''*, a cavity communicating with the anterior part of the chamber; *f'*, impression of the posterior adductor muscle; *g'*, impression of the anterior adductor muscle; *h'*, impression of the pallial muscle, or third adductor; *f*, posterior or large adductor (the single adductor of the *Ostracea*, *&c.*, corresponds to this, the following are superadded in other families of *Bivalves*); *g*, the anterior, antero-dorsal, or smaller adductor; *h*, the pallial or antero-ventral adductor; *i*, the convex muscular mass continued over the anterior part of the body, and reducing the opening of the mantle to the small slit,* through which a bristle is placed in *fig.* 5; (this mass is an inordinate development of what forms the muscular margins of the mantle lobes in other bivalves); *k*, muscular fibres of the *siphon*; *l* (*fig.* 6), the respiratory, or ingestive siphonic canal; *m*, the anal, or egestive siphonic canal; *n*, the labial or buccal appendage; *t*, the gills: in *fig.* 2 the right gill is seen partially protruded between the muscular parts of the mantle; *x*, part of the ovary (figures and description from Owen, to whose lucid memoir and illustrations the reader is referred for the anatomy of the internal parts); *fig.* 7, anterior termination of the shelly tube of *Clav. aperta*, *Sow.*, from Mr. Sowerby's Genera of Recent and Fossil Shells.

---

* John Hunter's paper in the 'Philosophical Transactions' for the year 1772, 'On the Digestion of the Stomach after Death,' and Spallanzani's experiments on that organ, will readily occur to the physiologist.

it was chambered, could not have been living far beneath the surface; whereas *Clav. lata* was dredged up from a depth of sixty-six feet. Any inferences, therefore, as to the state of submersion of a rock during the life of the fossil species of *Clavagella* which there occur, should be made with caution by the geologist.'

Geographical Distribution.—The diffusion of the genus, though now comparatively rare in cabinets, is probably wide. A sharp investigation of masses of coral and of submerged perforated rocks or stones, particularly in warm climates, is very likely to be rewarded by the discovery of *Clavagellæ*.

Probable place in the Natural System.—Mr. Owen is of opinion that the organization of *Clavagella*, like that of *Aspergillum* described in the 'Reise von Afrik' of Dr. Ruppell, is modelled on the type of the *Acephalous Bivalves*, and that it follows most closely, in the variations from that type, the modifications which have been observed in *Gastrochæna*. The lengthened worm-like figure of *Aspergillum* is exchanged in *Clavagella*, observes Mr. Owen, for a shorter form with greater lateral development: and instead of the small rudimentary valves, which are enchased, as it were, in the calcareous sheath of *Aspergillum*, we find them here largely developed, and one of them always remaining at liberty, to be applied by a powerful muscular apparatus to those offices which are essential to the forcible expulsion of the fluid in the branchial cavity, and probably to assist in the excavation of its secure abode.

FOSSIL CLAVAGELLÆ.

Mr. Broderip says that no fossil species appear to have been detected below the supracretaceous group. M. Deshayes, in his tables (Lyell, 3rd vol., ed. 1833), gives two living and seven fossil (tertiary) species, and one (*Clavagella aperta*, Sowerby) as found both living and fossil (tertiary). He gives the Mediterranean and Indian Ocean as the habitation of the living animal, and Sicily (Pliocene Period of Lyell) as the locality of the fossil. In his edition of Lamarck he makes the whole number (living and fossil) seven, the seventh and last species being *Clavagella aperta*; but he refers to Rang's 'Manuel' for a second living species. (See the 'Manuel' and Mr. Broderip's paper above referred to.) In Deshayes's edition of Lamarck the species *Clav. echinata* is followed by *Clav. cristata*, and the editor, in a note referred to from the latter, says that these two species should be united, as they only differ in size and age. He also observes that the free valve of *Clav. cristata*, or of *Clav. tibialis*, has been placed by Lamarck among the species of *Glycimeris* under the name of *Glycimeris margaritacea*. And here we may mention the difficulty of laying down specific characters from the valves, which being, as Mr. Broderip remarks, nearly, perhaps altogether, excluded from the light, colour, at best but a treacherous guide, is absent entirely; while the shape of the chamber and of the valves, together with the comparative roughness or smoothness of their outer surfaces, may depend upon the greater or less degree of hardness of the material in which the chamber is formed.

CLAVA'TULA. [SIPHONOSTOMATA.]

CLAVELLI'NA (Zoology), Savigny's name for a subgenus of ASCIDIDÆ, with a gelatinous envelope or test, supported like *Boltenia* upon a peduncle, and having the branchial sac without plaits, but not penetrating to the bottom of the envelope. Mr. W. S. Mac Leay (*Linn. Trans.*, vol. xiv., p. 539) observes that those figures of *Boltenia*, which represent them as supported vertically on a rigid peduncle, give them an unnatural position; that is, a position where the branchial pouch, and consequently the œsophagus, instead of descending, ascend. The peduncle, indeed, he adds, is clearly flexible in a natural state, in order that its drooping by the weight of the body may give this last a position analogous to that of other *Ascididæ*. When such animals exist, supported by a rigid peduncle, this must be inserted at the other extremity of the body, as in *Clavellina*, the compound family of *Botryllidæ*, and perhaps *Ascidia globularis* of Pallas and Lamarck. It seems, according to Mac Leay, necessary for the digestion of *Ascididæ*, if we may judge from their general construction, that the intestinal canal should form a loop or *ansa*. This loop may be either ascending, as in *Boltenia*, or descending, as in *Clavellina*; the only circumstance common to both genera being that the loop points towards the peduncle. Mr. Mac Leay thinks that in *Clavellina* the peduncle may possibly be a receptacle for the eggs, as in certain Cirripeds, and as it seems to be in the compound *Tunicata* of the family of *Botryllidæ*, but that whether it be also the case in *Boltenia* is not so certain. The student should refer to the second part of Savigny's admirable *Memoir upon the Invertebrate Animals* (Paris, 1816), and Mr. Mac Leay's interesting paper above quoted.

CLAVICHORD (or, improperly, *clarichord*), a musical keyed instrument, much in use till the middle of the last century, but now only to be met with as a curiosity. Its shape is that of a square piano-forte, though smaller, and the strings are struck, or rather pressed, by brass pins projecting from the further end of the keys. The tones of the Clavichord are rendered exceedingly soft by means of pieces of cloth interwoven with the strings. This softness was its great recommendation in convents, the nuns having thereby been enabled to practise without disturbing others in the dormitory.

CLAVICO'RNES (Entomology), a name given by Latreille to a subsection of Coleopterous insects of the section Pentamera.

The insects of this subsection almost always have the antennæ thickened at the apex, and frequently the terminal joints forming a club: the joints of the tarsi are usually entire.

Such are the principal characters of the subsection Clavicornes, a group in which Latreille includes the families *Scydmænidæ*, *Histeridæ*, *Silphidæ*, *Scaphididæ*, *Nitidulidæ*, *Dermestidæ*, *Byrrhidæ*. We thought it proper to notice this subsection, since it is adopted by many of the continental entomologists. It appears to us, however, to include many genera of insects, which, in a natural arrangement, ought not to be associated under one head.

CLA'VIGER. [PSELAPHIDÆ.]

CLAVI'GERO, FRANCESCO SAVERIO, was born at Vera Cruz, in Mexico, about 1720. He entered the order of Jesuits, and was sent as missionary among the Indians in various parts of Mexico, where he says, in the preface to his work, he spent thirty-six years, visiting the country in every direction, living at times entirely among the Indians, whose language he learned, collecting their traditions, and examining the historical paintings, MSS., and monuments relative to the antient history of the aboriginal tribes, with the view of writing a correct account of Mexico; since he had found, on reading the Spanish authors who had preceded him, that their works were disfigured by many errors and misrepresentations. After the Jesuits were suppressed by Spain in 1767, Clavigero left Mexico for Italy, where the Pope granted to the expelled fathers an asylum in the States of the Church. Clavigero, and others of his brethren from Spanish America, had the town of Cesena assigned to them as their residence; a circumstance which gave Clavigero a good opportunity of comparing his own information with that collected by his brother missionaries in various provinces of Spanish America. He now set about writing his History of Mexico, which he published in Italian, 'Storia antica del Messico cavata dai migliori Storici Spagnuoli, e dai Manoscritti e dalli Pitture antiche degl' Indiani,' 4 vols. 4to. Cesena, 1780–1, with maps and plates, which he dedicated to the learned Carli. In the first volume, after a long and critical list of all the Spanish writers on Mexico, the author gives an account of the countries constituting that empire; of their natural history, of their early inhabitants, their various migrations, and of the establishment of the dominion of the Aztecs, and concludes with a sketch of the political state of the country when Cortes landed on its shores in 1521. The second volume treats of the manners, customs, arts, sciences, and language of the people. The third, which contains the account of the conquest by Cortes, is written with great impartiality. The author feels as a Mexican rather than a Spaniard. The fourth volume consists of dissertations on the physical and moral constitution of the antient Mexicans, on their progress in the arts and sciences, on their religion, on the proper boundaries of the empire of Anahuac; and lastly, the author gives a list of works written in the various native languages since the conquest, either by Spaniards or natives. Clavigero indignantly refutes the assertions of Paw, Raynal, and others, who chose to consider the Indians of America as an inferior race, little removed from the brute creation. In these dissertations Clavigero has at times shown more industry and honest zeal than critical discrimination. His work however, is, upon the whole, the best that has been written on antient Mexico; Humboldt, Navarrete, and other recent writers often refer to it. [Aztecs.] It was translated into English by C. Cullen: 'The History of Mexico,' 2 vols., 4to., London, 1787. Little is known of Clavigero's private life. He died in the Papal State towards the end of the last century. Clavigero, although the author of a most important Italian work, has been singularly neglected by the Italian bibliographists and biographists. His name is not even mentioned in Lombardi's 'Literary History of Italy in the Eighteenth Century.'

CLAVIPA'LPI (Entomology), according to Latreille, the seventh family of Tetramerous Coleoptera.

The insects of this family are principally distinguished by the antennæ being terminated by a perfoliate club. The tarsi are generally furnished with a velvet-like substance beneath, and have the penultimate joint bilobed; some few, however, have the tarsi simple. The mandibles are emarginated or dentated at the apex; the maxillæ are armed on the inner side by a tooth-like process; the palpi have the terminal joint large. Many of the species of this group feed upon fungi and boleti, and their form is often rounded and convex. The genera included in the family Clavipalpi are *Erotylus*, *Triplax*, *Languria*, *Phalacrus*, *Agathidium*, and some others.

CLA'VIUS, CHRISTOPHER, of Bamberg, entered into the order of Jesuits, and died at Rome February 5, 1612, aged 75. He was selected by Gregory XIII. to superintend the reformation of the Calendar, in which capacity he had to endure and reply to the attacks of Moestlinus, Joseph Scaliger, Vieta, and others of less note. As a mathematical writer, Clavius is distinguished by the number of his works, the frequency with which they were reprinted, his rigid adherence to the geometry of the antients, and the general soundness of his views. According to Riccioli (*Chronicon*, *Nov. Almag.*), the most learned Germans resorted to Rome, that they might converse with Clavius, and several were accustomed to say that they would rather be attacked by him than praised by others. As Clavius did not possess any great original talent, his works are now of little consequence, except to the mathematical historian. The following is the list of those which have been mentioned by succeeding writers:—

(1.) In 'Sphæram Johannis de Sacro-bosco Commentarius,' Rome, 1570, reprinted more than a dozen times: the last edition we can find is that at Leyden, 1618. (2.) The Works of Euclid, with a commentary; Rome, 1574; Cologne, 1591; Frankfort, 1607, &c., &c. (3.) 'Epitome Arithmeticæ Practicæ,' Rome, 1583; Cologne, 1637, &c. (4.) Edition of the Spherics of Theodosius, with a Table of Sines, Tangents, &c.; Rome, 1586. (5.) A work on Gnomonics, Rome, 1587; several times reprinted. (6.) 'Defence of the Calendar against Moestlinus;' Rome, 1588. (7.) 'Fabrica et Usus, &c.,' a work on Horology; Rome, 1586; 'Constructio, &c.,' a second work; Louvain, 1595; 'Horol. Nov. Descr., &c.,' a third; Rome, 1599. (8.) On the Astrolabe, Rome, 1593, &c. (9.) Refutation of J. Scaliger on the Calendar, Rome, 1595; Mayence, 1609. (10.) 'Romani Calendarii a Greg. XIII. Restituti Explicatio,' Rome, 1603. This is to us the most important of the works of Clavius: it contains the description of the reasons and methods employed in the alteration of the calendar, with the answer to Vieta and others. (11.) 'Elements of Algebra,' Rome, 1604. (12.) 'Geometria Practica,' Rome, 1604. (13.) 'Refutation of George of Wirtemberg on the Calendar,' Rome, 1610. We have taken the earliest editions which we could find in any of the authors cited at the end.

A complete edition of the works of Clavius was published at Mayence in 1612. The account of the Calendar is in the fifth and last volume. (Riccioli, Weidler, Blancanus, Lipenius, Bouillaud (*Cat. Bibl. Thuan.*), Lalande, Delambre.)

CLAVULA'RIA. [Zoophytaria.]

CLAVULI'NA, D'Orbigny's name for a genus of his family Hélicostègues, order Foraminifères. [Foraminifera, Symplectomerea.]

CLAY, any natural mixture of earths which breaks down or disintegrates in water, and affords a plastic ductile mixture. It depends upon this property, rather than colour or composition, whether an earthy body belongs to the class of clays. There are many varieties of clay used for different purposes.

Pipe-clay is of a greyish-white colour, has an earthy fracture, and a smooth greasy feel; it adheres to the tongue, and is very plastic, tenacious, and infusible. Its name shows the purpose to which it is applied. It is found near Poole in Dorsetshire.

Potter's clay is of various colours, and disintegrates by exposure to the air; when mixed with sand, it is made into bricks and tiles. It is found in Hampshire, Berkshire, Devonshire, and is largely used in the Staffordshire Potteries. The Hampshire clay yielded by analysis,—

Silica . . .	51
Alumina . . .	25
Lime . . .	

with some oxide of manganese and water

Stourbridge clay has the general properties above described, but is of a dark colour, owing apparently to an admixture of carbonaceous matter. It is most extensively employed in the manufacture of crucibles, and especially for those used in glass-making. It is extremely refractory in the fire. It yielded by analysis,—

Silica	57
Alumina	30
Moisture	12·6

A trace of iron and carbonaceous matter.

It appears to have originated from the disintegration of shale.

Brick clay, or loam, varies much in appearance, texture, and composition; its colour is dependent upon the proportion of oxide of iron which it contains. It lies in abundance upon the London clay, and frequently rests upon an interposed bed of sand. The organic remains found in it are few, but it sometimes contains the teeth of elephants.

London clay is a very extensive deposit of a bluish clay, except near the surface, where it has often the usual clay colour. It forms the greater part of Middlesex, the whole of Essex and Suffolk, and part of Norfolk, and frequently rises almost to the surface. Some of the lower beds are yellowish white or variegated. This clay occasionally includes beds of sandstone, and of a coarse argillaceous limestone, of which Parker's Roman cement is made. It contains also frequently the bones of the crocodile, turtle, &c.

Plastic clay skirts the London clay within the London chalk basin, and it appears also at the Isle of Wight. This formation consists of a variable number of sand, clay, and pebble beds irregularly alternating, lying immediately upon the chalk; it contains some appearance of coal, decidedly of vegetable origin, pyrites, oyster-shells, and the branches of trees. The sand-beds of the plastic clay formation are the grand reservoir of soft water from which the deep wells in and round London are supplied.

Porcelain clay is of various shades of white; it is dull and opaque; occurs friable or compact; feels soft to the fingers, and adheres to the tongue. It is infusible, and its specific gravity is 2·216. A large tract of this clay, which includes crystals of felspar, quartz, and mica, occurs near St. Austell, in Cornwall. The porcelain manufactures of Worcester are supplied from it; according to Wedgwood, it consists of 60 parts alumina and 40 silica. It probably arises from the decomposition of felspar. The porcelain clay of China is called *Kaolin*. This clay occurs in France, Saxony, and Austria. Various other kinds of clay are met with in different situations; their nature and composition depend upon those of the rocks from the disintegration of which they have been formed; thus slate, steatite, and trap, each yields a different kind of clay.

Clay is an essential component part of all fertile soils. A clay soil consists of a large proportion of alumina [Alumina] united to silica of various degrees of fineness, and frequently also a portion of carbonate of lime. When the silica is very fine and intimately mixed with the alumina, the clay, although stiff in appearance, is fertile in proportion to the humus which it contains, or which is artificially added to it. It then forms that class of rich wheat soils which produce many successive abundant crops without change or manure. It has a strong affinity for water, which prevents the plants that grow in it being injured by drought; and it has a sufficient degree of porousness to allow superfluous moisture to percolate without making it too soft. All that is required for such a soil is a porous substratum of rock or gravel; and where this is not the case, sufficient under-drains must be made to produce the same effect. The clay soils in Britain are not in general of this fertile kind. They are of a compact nature which retains the water; and the various oxides and salts of iron which they contain are mostly injurious to vegetation. Hence they require expensive draining, and manuring, to render them productive. This has made lighter soils, which are more easily worked, to be generally preferred, although naturally less adapted to the growth of wheat; and the mode of cultivation of the light soils has advanced more rapidly towards perfection than that of the clays. Yet the latter will undoubtedly repay the outlay best, when once they are brought to a certain state of improvement. When clay soils are well drained, and when the effect of noxious salts has been removed by liming, burning, and frequent stirring, it will be found that a much smaller quantity of manure will produce a certain return in grass or corn, than on any light soil. The great difficulty is to choose the time when stiff clays are to be worked; and here it may be observed, that ploughing sometimes does more harm than good. When clay is wet, especially in the beginning of summer, and it is ploughed in the regular process of fallowing, the tough moist slice cut out by the plough is set on edge, and the sun bakes it into a hard mass like brick. In this state it is not improved by exposure to the air, which cannot penetrate this hard substance. It would be much better to plough out deep water-furrows with a plough made on purpose, and wait until the moisture is reduced by gradual percolation and evaporation; so that the plough should raise a slice ready to break and crumble as it is turned over. This should be done immediately before winter, and then the frost will so divide and mellow the soil, that, provided it be kept free from superfluous water by under-drains and water-furrows, it will have the appearance of the finest mould when worked with the harrows in spring. To plough it again would be to spoil all. It should have received the necessary manuring in autumn, and be ready for the seed to be sown on this pulverized surface. The horses which draw the harrows or the sowing machines should be made to walk in the furrows, which should afterwards be deepened out with the spade, or by a plough constructed for the purpose. A free course and outlet should be formed for all surface water; for no maxim is more true than this, that stiff clays are never injured by a continuance of dry weather, unless they were in a wet state immediately before. The dryest clay contains sufficient water to supply the roots of plants for a long time; but wet clay in drying and shrinking destroys the texture of the roots by mechanical pressure. This may be of use when weeds are to be eradicated, and in that case a different mode of proceeding may be recommended; but when good seed is sown, the clay should be in such a state as to crumble under the harrows, and it should not be too moist. Experience has taught the ploughman, that clay soils should be laid in round lands or stitches: and much of the produce of a field depends on the skill with which this is done. It is not only the surface which should lie in a rounded form, but the bottoms of the furrows should lie in a regular curve, without small ridges or inequalities between them; so that when heavy rains penetrate through the whole thickness which the plough has raised, the water may find its way into the intervening furrows, without being retained by the small ridges left by an unskilful ploughman. It is seldom that a common labourer can be made to perceive the consequences of his carelessness. The slightest inclination of the plough to either side makes an inclination in the bottom of the furrow. An inequality in the depth does the same. The usual method is to increase the depth of the ploughing from the crown of the stitch to the outer furrow. If the land has been cross-ploughed or dragged level before the last ploughing, this may answer the purpose; but if the stitches are only reversed, and the centre of the new stitch is to be where the water-furrow was before, it requires twice ploughing to bring the stitch to its proper form, and this is not always done, for fear of treading the land too much. Hence it is always preferable, where it can be done, to lay the land flat by cross-ploughing and harrowing before it is raised in stitches. The narrower the stitches are, the dryer the land will lie. The most convenient width is five bouts, as it is called, that is, five furrows on each side of the centre, which, allowing 9 inches for each furrow, makes 7½ feet, leaving 18 inches for a water-furrow, which is deepened into a narrow channel in the middle.

We have been thus particular in describing the management of clay land, because it seems not so generally understood, and there is great room for improvement in the common modes of cultivation. Fallowing for wheat is the old system on clay soils, and continues to be so in nine farms out of ten; but it often happens that in a wet season the whole advantage of the repeated ploughings is entirely lost, the land sown with wheat is neither enriched nor improved by all the tillage bestowed upon it, and is as full of weeds as it was when first broken up from the preceding stubble. The better system is to clean the land well in summer, after it has borne a crop of winter tares, which have been cut green or fed off by sheep in May or June, and to lay it up high and dry for the winter, after having given it the proper liming and manuring; to sow it with oats and grass seeds in spring, keep it in grass as long as is convenient, and break it up in autumn. Wheat may then be sown; or it may have the benefit of another winter's frost, and beans may be drilled or dibbled early in spring. After harvest the bean stubble may be cleared with harrows or scarifiers, and the seeds allowed to vegetate; the plough will then destroy them. A good crop of wheat may be depended upon after this, if the land is in good heart; if not, it should have been manured for the beans: but if the grass was fed off the preceding year, and the land well managed before, it cannot fail to be in good heart. Clay land will bear a repetition of the same crops much oftener than lighter lands; but every scientific agriculturist knows the advantage of varying the produce as much as possible, making plants of different families succeed each other. The cereal grasses are of one family, which is the reason why wheat, barley, oats, rye-grass, &c., do not succeed so well after each other as after leguminous plants or clover, and that turnips, besides cleaning the land by the repeated hoeings given them, are so good a preparation for corn. A good rotation for stiff clays is yet a desideratum in agriculture; and although we will not affirm that fallows can be entirely dispensed with, we are persuaded that they might be separated by much larger intervals than is usually done. And if advantage is taken of early seasons, at least in the southern parts of the island, most lands may be kept clean by what is called a bastard fallow immediately after harvest, without losing a crop. We will go farther, and assert that instead of three crops in four years, which is the common method, and an improvement on the old system of two crops and a fallow, five might easily be obtained, especially if tares and trifolium incarnatum are considered as crops. For example: 1. Oats or barley; 2. Clover; 3. Wheat; 4. Trifolium cut in May, and succeeded by spring tares, cabbages, or potatoes. At all events the trifolium or winter tares may always be had in the year in which the land is to be cleaned by repeated ploughings; as they may be cut early in summer, and leave ample time for the operations.

The most profitable management of a stiff wet clay soil, after thorough draining it, is to cultivate it on the convertible system; that is, to have it three years in grass and three years under the plough, unless a permanent and good sward can be obtained upon it, in which case it will give the surest return by remaining in grass. A preliminary course of cropping with ample manuring will so much improve the texture of the surface, that a much better herbage will grow upon it; and when this is well established, it may be left so until it degenerates.

The great disadvantage of clay soils in a moist climate like that of Great Britain arises from an excess of water, and the obvious remedy is perfect draining of the subsoil. This is effected by numerous hollow drains judiciously arranged to convey the water to a proper outlet. An instrument has been lately invented or improved by which this is done effectually, and at a comparatively small expense. [DRAINING.]

Clay is extensively used in many parts of England to improve light land, by being carried on the surface in considerable quantities, but this is chiefly where it approaches to the quality of marl, by having a considerable portion of calcareous earth in its composition.

The effect of burnt clay as a manure has been highly extolled, and not without some reason in particular situations. Clay by burning alters its nature; it becomes insoluble in water, and loses its attraction for it; it then resembles silicious sand, and may greatly improve a very strong retentive clay, tempering it and rendering it more porous. To burn clay, it is dug out in lumps and dried; heaps are made of these at regular distances in a field, with a small cavity in the centre, in which dry furze and brushwood are introduced. This being lighted, the fire is allowed to burn very slowly, and the smoke kept in by adding a sod or clod wherever it bursts out. When the heap is once burning more clay may be added, even without being dry, and the combustion goes on without other fuel. It must be so managed as to bake the clay without heating it too much; and when the heaps are cooled and opened the whole should appear pulverized, and of a red colour if oxide of iron exists in the soil. A coat two or three inches thick spread over a field and ploughed in will greatly improve its texture; but sufficient animal or vegetable manure must be added to make it fertile.

CLAY SLATE. [SLATE.]

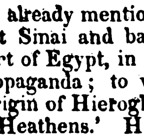
CLAYTON, ROBERT, Bishop of Clogher, was born at Dublin in 1695, and educated at Westminster School and Trinity College, Dublin. He was successively appointed to the sees of Killala, Cork, and Clogher, although his orthodoxy seems to have been very doubtful from his first entrance into the church. His preferment was chiefly owing to a lady who was connected with his family by marriage—Mrs. Clayton, afterwards Lady Sundon, who was one of Queen Caroline's chamber-women. His first published work was 'An Introduction to the History of the Jews.' This was followed by 'The Chronology of the Hebrew Bible vindicated' (published in 1747). 'A Dissertation on Prophecy' (in 1749): and 'An Essay on Spirit' (1751). This essay, which was full of the notions contained in what is called the Arian heresy, gave great offence to the Church, and prevented his being promoted to the archbishopric of Tuam. There is some doubt whether Clayton was really the author of it, but he soon avowed all the sentiments which it contained, and even more, in his 'Vindication of the Old and New Testament, in answer to the Objections of the late Lord Bolingbroke, in Two Letters to a young Nobleman;' which was published at different periods in three separate parts.

On the 2nd of February, 1756, he made a motion in the Irish House of Lords for the expunging of both the Athanasian and Nicæan Creeds from the Liturgy. The motion, which did not find a single supporter in the House, created a violent storm at court and out of doors; and when he renewed his attack in the following year, in the third part of his 'Vindication of the Old and New Testament,' &c., it burst upon his head. The king instructed the lord-lieutenant to bring on a legal prosecution of the bishop, but before the day fixed for the opening of the proceedings he was carried off by a nervous fever. He died February 26, 1758.

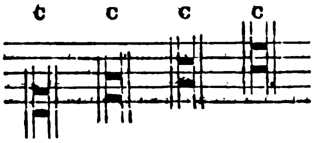
Besides the works already mentioned, he published 'A Journey from Mount Sinai and back again,' from a MS. written by the Prefect of Egypt, in company with the missionaries of the Propaganda; to which are added some 'Remarks on the Origin of Hieroglyphics, and the Mythology of the ancient Heathens.' He was a man of great generosity and benevolence, and his charities were frequently well directed. He gave away many reels and spinning-wheels to the poor about Clogher, encouraging industry, and teaching them to provide for themselves.

CLEF (Fr. *clef*, a key), in music, a character placed at the beginning of the staff, to give names to the lines and spaces, and determine the acuteness or gravity of each note.

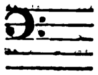
There are three clefs—the *treble*, the *mean* (or C clef), and the *base*. The *Treble Clef* is now only placed on the second line, which it names G.



The *Mean Clef* gives the name of C to any line on which it is placed: it is called the *soprano clef* when placed on the 1st line, the *mezzo-soprano* when on the 2nd, the *alto*, or *contratenor*, or *countertenor*, when on the 3rd, and the *tenor* when on the 4th.



The *Base Clef* is now placed only on the 4th line, giving it the name of F.



The treble clef is appropriated to female and boys' voices, and to instruments whose scales run high. Of the four kinds of *mean clef*, the first is used for female and boys' voices; the third and fourth for men's voices, also for the viola, the two higher trombones, and occasionally for the clarinet and violoncello. The *base clef* is appropriated to the lowest male voices, and to instruments the scales of which run deep.

In the 17th century the treble clef was used on both 1st and 2nd lines, and the base on both 3rd and 4th. The correction of so great an evil was a step towards simplification; and, in 1672, a distinguished mathematician (Thomas Salmon, M.A., of Trinity College, Cambridge) published his plan for a complete amelioration, by the abolition of all clefs, and substituting for them one universal character. The plan was simple and feasible, but immediately, violently, and successfully opposed by the musicians of the day, at the head of whom, we regret to say, was Matthew Lock. Thus was strangled in its birth a most rational attempt to remove much of the difficulty attending the practice of music. The C clef is now gradually falling into disuse, but we fear that its final rejection is not near at hand, and that a long time will elapse before other desirable reforms in music—reforms that would remove many of the impediments to the practice of the art—will be accomplished, so blind and so strong is prejudice.

CLEIDOTHÆRUS, a genus of Acephalous mollusks (Conchifers of Lamarck), established by Mr. Samuel Stutchbury for a testaceous animal, the mechanism of whose hinge connecting the two valves differs most materially from that exhibited by other bivalves.

Shell bivalve, somewhat pearly, inequivalve, involute, attached by the outside of the larger valve. Hinge with a small conical pointed tooth in the free valve, fitting into a corresponding pit in the attached valve. A testaceous, rather elongated, curved appendage, connected by cartilage, is inserted into a deep cicatrix within each umbo; muscular impressions, two in each valve, lateral, the anterior ligulate, the posterior suborbicular. Muscular impression of the mantle entire. Ligament external. (Stutchbury, modified by G. B. Sowerby.)

M. De Roissy had separated the genus from *Chama*, with which it might be easily confounded by a superficial observer under the name of *Camostrée* (*Chamostrea*), but he does not seem to have been aware of the appendage, and, as Mr. Stutchbury observes, his name is entirely inapplicable, there being nothing in the shell to connect it with *Ostrea*. Example, *Cleidothærus Chamöides*. (Stutchbury.)

Description. Shell involute, brownish red, internally of a greenish pearly lustre, attached by the anterior side of the right valve, which is of great depth; left valve but slightly convex; the clavicular appendage with a groove on the convex side. (Stutchbury.)

Locality.—Mr. Stutchbury states that *Cleidothærus Chamöides* was found attached to sandstone rocks by T. Young, Esq., R.N., together with an *Aspergillum* (perhaps *agglutinans* of Lamarck), some *Chamæ*, &c., while searching near the entrance of Port Jackson, pointed out to him as the spot where Mr. Stutchbury discovered, in 1826, the first living *Clavagellæ*. Mr. G. B. Sowerby says that some imperfect specimens had been sent to England many years ago, probably from the same spot, by Mr. A. Humphrey. Some of these were of a brownish red colour, whereas those procured by Mr. Young were of a dull livid colour. The imperfection of the specimens above alluded to consisted in their having lost the internal appendage. All the specimens had adhered by the anterior side of the large and deeper valve. Mr. Stutchbury says that in general contour this shell has so great a similitude to Chama, that without opening it there would be no hesitation in pronouncing it of that genus, belonging to Lamarck's division, 'Crochets tournant de droit à gauche;' a division which it seems will not bear the test of examination. [CHAMACEA.*]

---

[*] Lamarck and Deshayes both make *Diceras* feminine, and the cut [Article CHAMACEA], in conformity with them and other zoologists, is named *Diceras arietina*; but there can be no doubt that, correctly, it should be *arietinum*, *Diceras* being a Greek noun from κέρας, a horn. In the same article, p. 470, 2nd column, line 23rd upwards from the cut, for *Chama* read *Chamæ*.

Mr. G. B. Sowerby is of opinion that as far as the character of the internal hinge cartilage having an elongated testaceous appendage goes, *Cleidothærus* connects the *Camacées* (*Chamæ*) of Lamarck with his *Myaires*. For figures and further description, the reader is referred to the *Zoological Journal*, vol. v., p. 97; *Tab. Supp.* xlii., figs. 5, 6, 7, 8; and Mr. G. B. Sowerby's *Genera of Recent and Fossil Shells*, No. xxxii.

CLEI'STHENES, an Athenian, one of the family of the Alcmæonidæ, was grandson of Cleisthenes, the tyrant of Sicyon. After the expulsion of the Pisistratidæ (B.C. 510) he changed his line of politics and headed the democratical party: the opposite faction was conducted by Isagoras. Cleisthenes soon obtained the favour of the people, and the sanction of an oracle from Delphi enabled him to effect changes in the constitution of Attica which were productive of very important results. The four tribes into which Attica had antiently been distributed gave place to a division altogether new. He made ten tribes, called severally from the name of some hero: each tribe contained a given number of demi (δῆμοι), or townships, which were under the direction each of a demarch (township-governor). Every citizen was obliged to have his name enrolled in the register of some township. Many other changes were also effected. The senate was increased from 400 to 500; 50 were sent by each tribe. The process of ostracism is said to have been first formally established by Cleisthenes. The Spartan king Cleomenes, acting on the suggestions of Isagoras, insisted on the expulsion of Cleisthenes and the *accursed* persons. (Herod. v. 70.) Cleisthenes left Athens (Herod. v. 72), but waited a favourable opportunity for prosecuting his schemes. Seven hundred families were banished at the same time. (Herod. v. 72.) When Cleomenes and Isagoras were besieged in the citadel which they had occupied, and were forced to capitulate, they left Athens with the Spartan troops, and Cleisthenes with the 700 families returned in triumph. [ATTICA.] (Thirlwall's *Greece*, vol. ii. pp. 73—80; Niebuhr's *Rome*, vol. ii. p. 305, &c. *Eng. transl.*)

CLE'MATIS, a genus of climbing plants belonging to the natural order *Ranunculaceæ*, and characterized by having a valvate coloured calyx, carpels in a ripe state terminated by long feathery styles, and opposite leaves. The most common species is *C. vitalba*, the 'Traveller's Joy,' which runs over the hedges in many parts of England, loading them first with its copious clusters of white blossoms, and afterwards with heaps of its feather-tailed silky tufts. It is however better known from some of the exotic species being favourite objects of cultivation. *C. flammula*, a species with panicles of small white flowers, is among the most fragrant of plants. *C. cirrhosa, crispa, et florida*, are remarkable for the large size of their greenish-white flowers; while the purple or pink bells of *C. viticella*, hanging gracefully from its festooning branches, render that species, when well managed, one of the most elegant and ornamental of climbers. Atragenes, Siberian and Alpine plants, with finely-cut leaves and delicate purple flowers, considered a peculiar genus by Linnæus, are other species of Clematis. They have a climbing habit, and are occasionally seen in gardens; their stems however are apt to become naked, and they are not so generally cultivated as the species of genuine Clematis.

All these plants are hardy; but they are impatient of damp in winter. The latter circumstance is therefore to be attended to by those who wish to ornament their gardens with them.

CLE'MENCE, ISAURE, a French poetess, born near Toulouse, but at what time has been a matter of much dispute. The first known writer who spoke of her is Guillaume Benoit, a jurist of the fifteenth century, who says that she instituted the floral games, 'jeux floraux,' at Toulouse, which were held yearly on the 1st of May, and that she instituted prizes for those who distinguished themselves in various kinds of poetry. The prizes were a gold violette, a silver eglantine, and a gold souci or marigold. This distribution of prizes continued till the Revolution. The capitouls or echevins of Toulouse distributed the prizes, on which occasion an eulogium was recited in memory of Clemence Isaure, and her statue in the Hôtel de Ville was crowned with flowers. In 1527, Etienne Dolet, [illegible] riter and printer at Lyon, who was hanged and [illegible] y in 1546, wrote an eulogium of Clemence [illegible] with the title, 'De Muliere quâdam quæ Ludos literarios Tolosæ constituit.' These writers were followed by numerous others, and among them De Thou and the President Berthier, who wrote about Clemence, and placed her existence in the fourteenth century. Catel, however, in his *Mémoires du Languedoc*, expressed doubts on the subject, and treated the existence of Clemence as fabulous. Dom Vaissette, *Histoire du Languedoc*, supports the personality of Clemence, and her foundation of the prizes, as proved by tradition, instruments, and public documents in the Hôtel de Ville of Toulouse. In 1775 a Memoir appeared, in which Clemence Isaure is stated to have lived in the latter half of the fifteenth century. This controversy seems to have originated in having attributed to Clemence Isaure the original foundation of the poetical academy known by the name of the floral games. But that academy was founded long before Isaure by the troubadours, and was called the college of 'la gaie science,' or 'gai sçavoir.' The first authenticated meeting on record dates from the year 1323; they then assembled in a garden outside of Toulouse. The registers of this college, till about 1500, make no mention of Isaure. It may be about this latter period that she founded the prizes of gold and silver flowers, from which the academy took its more recent name. The accounts of Isaure's life and adventures which are found in several compilations appear very problematic. (*Encyclopédie Méthodique, Histoire*, art. 'Isaure;' and Moreri's *Dictionnaire*.)

CLEMENS, TITUS FLA'VIUS ALEXANDRI'NUS, was born about the middle of the second century of our æra. According to St. Epiphanius he was an Athenian, and at first a follower of the Stoic philosophy; but according to others he belonged to the Platonic school, an opinion which seems countenanced by the manner in which he speaks of Plato and his philosophy in many passages of his writings. He says in his Stromateis (lib. i.), that 'he had for teachers several learned and excellent men; one an Ionian, who lived in Greece, another from Magna Græcia, a third from Cœlesyria, a fourth from Egypt, and others who had received the Christian doctrine in the East, of whom one was from Assyria, and the other from Palestine, of an antient Hebrew family; but that at last he found in Egypt one superior to all, with whom he remained.' This was Pantænus, whom he repeatedly mentions in his works, and who kept a Christian school at Alexandria, in which capacity Clemens succeeded him. St. Jerome says that Clemens was teacher of the catechumeni in that city. He was ordained presbyter of the church of Alexandria, where he appears to have remained the rest of his life. His death is believed to have happened about A.D. 220. Among his disciples were Origen, and Alexander, afterwards bishop of Jerusalem. He left many works, in which he has mixed with the precepts of the Christian doctrine and morality, which it was his object to inculcate, much information concerning the learning, philosophy, history, and manners of the heathens. Of the earlier Christian writers, he is the most conversant with the science and learning, with the opinions and practices, of the various nations of that day; and his works are extremely interesting, as showing the state of society, both among Heathen and Christian subjects of the Roman empire at that early time. They also contain much information on antient history, chronology, and the various schools of philosophy; many extracts from antient writers, whose works are lost; and also accounts of the early heresies and schisms which divided the primitive Christian church. The works of Clemens which have come down to us are:—1. 'Exhortation to the Greeks,' 1 book. This is an exhortation addressed to the heathens to abandon their false gods, whose absurd stories and obscene adventures he exposes by the testimony of the poets and philosophers of antiquity. 2. 'Pædagogus,' in 3 books. This is a treatise on Christian education. He begins by describing the qualities required in a teacher, and also what he ought to teach his pupils; he then gives an exposition of Christian ethics, recommends temperance, decency, moderation in the enjoyments of life, and declaims against the effeminate manners and luxury of his time, against public baths, and other practices which led to laxity in morals. His satire of the vices and follies of the age is caustic and humorous, and reminds us at times of Juvenal. When we reflect that he lived under the reigns of Caracalla and Heliogabalus, we do not feel inclined to suspect him of exaggeration. 3. 'Stromateis,' (τῶν κατὰ τὴν ἀληθῆ φιλοσοφίαν γνωστικῶν ὑπομνημάτων στρωματεῖς η') in 8 books. The word stromateis he has used to mean a party-coloured or patch-work; 'opus varie contextum,' from the multifarious kind of information, religious and profane, anecdotical, historical, and didactic, put together without much regard to order or plan. Clemens says that he adopted this want of arrangement 'to veil the doctrines of Christianity under the maxims of profane philosophy, in order to screen them from the eyes of the curious and the uninitiated, that those only who are intelligent, and will give themselves the trouble of studying, may understand the meaning.' Probably also he found this style of composition better adapted for his multifarious information, and best suited to his old age, in which he apparently wrote it. In the first book he descants upon the utility of philosophy, and concludes by asserting, by the help of chronology and quotations, that the philosophy contained in the sacred books of the Hebrews was the most antient, and that other nations had borrowed much from it. In the second he treats of faith, sin and repentance; he asserts the free will of man, condemns licentiousness, commends lawful marriage with one wife and one alone. In the third he continues the preceding subject, condemns the incontinence of the Nicolaites, Valentinians, and other early heretics, and defends marriage against the Marcionites. He says the apostles Peter and Philip were married and had children. He discountenances second nuptials, without absolutely condemning them. He speaks also with great praise of virginity, when preserved for the love of God and according to his ordinances. In the fourth book he treats of Christian perfection and martyrdom, exhorting the Christians to submit to death for the love of God and of Christ. Perfection he places in the precept of loving God and our fellow-creatures. In the fifth he shows that the method of speaking by figures and symbols is very antient, both among the Hebrews and the Greeks; the Greeks, he says, borrowed most of the truths they have written from those whom they called barbarians, and especially from the Jews. This book is full of quotations from antient poets and other writers. In the sixth and seventh books he sketches the portrait of a true Gnostic, a term which with him is synonymous with that of a perfect Christian. It is a complete model of moral conduct. He combats the reproach of the Greeks about the divisions and schisms existing among the Christians. He says that schisms will arise in any community; that they were foretold by Christ; that they had existed among the heathens and the Jews; that the way to ascertain the truth is to consult the Scriptures, and the whole Scriptures, and not merely some parts of them, and to follow the tradition of the church; that there is only one universal church, older than all heresies, that it began under Tiberius, and was promulgated all over the world under Nero, while the older heresies date only from the reign of Hadrian. He then recapitulates the subjects of his seven books, and promises to begin the next by a new subject. The eighth book, as we have it in our editions, differs altogether from the rest, being a treatise on logic. Photius, in his Bibliotheca, says, that in some editions in his time the eighth book of the Stromateis consisted of the treatise 'Can a rich man be saved?' which however is generally placed as a distinct work, after the eight books of the Stromateis. This treatise has also been published separately, with a copious and learned commentary by a professor of Utrecht. 'Clementis Alexandrini liber: Quis dives salutem consequi possit, perpetuo Commentario illustratus a C. Seegario,' 1816. Among the works of Clemens which are lost was the 'Hypotyposeis,' or Commentaries on various parts of the Scriptures, in eight books, mentioned by Photius, who quotes several passages, and severely condemns it as heretical. (Photius among the *Testimonia*, at the beginning of Clemens' works, Potter's edition.) This seems rather strange, as the other works of Clemens have been esteemed perfectly orthodox, and greatly commended by Eusebius, Jerome, and other antient fathers, with the exception perhaps of one or two obscure passages concerning the nature of Christ and original sin. The errors however ascribed to the 'Hypotyposeis,' may be accounted for in some manner by the supposition that it was an earlier work of Clemens, written before he was properly instructed in the Christian doctrines, and while he was still much imbued with his Platonic philosophy. Upon the whole Clemens is more of a Christian philosopher and moralist, than a professor of dogmatic theology. Some believe that the 'Excerpta ex Scriptis Theodoti et Doctrina quæ Orientalis vocatur,' which appear at the end of Clemens' works, as well as some other fragments, are extracts from his 'Hypotyposeis.' He also wrote several treatises, 'De Pascha,' 'De Jejunio,' 'De Obtrectatione,' &c., which are lost. Clemens' works were published, with a Latin translation, by J. Potter, 2 vols., folio, Oxford, 1715; and also at Würzburg, 3 vols., 8vo., 1780.

CLEMENT I., or CLEMENS ROMANUS, succeeded Anacletus as bishop of Rome in the latter part of the first century of our æra. The chronology of the early bishops of Rome has been the subject of much controversy. One of the earliest authorities, Irenæus, bishop of Lyon, who lived in the latter part of the second century, says, that 'when the blessed apostles, Peter and Paul, had founded and established the church at Rome, they delivered the office of the bishopric in it to Linus. To him succeeded Anacletus, after whom, in the third place after the Apostles, Clement obtained that bishopric, who had seen the blessed Apostles and conversed with them; who had the preaching of the Apostles still sounding in his ears, and their traditions before his eyes. Nor he alone, for there were still many alive who had been taught by the Apostles. In the time therefore of this Clement, when there was no small dissension among the brethren at Corinth, the church at Rome sent a most excellent letter to the Corinthians, persuading them to peace among themselves,' &c. This is the epistle which is ascribed to Clemens Romanus, by Clemens Alexandrinus, Origen, Eusebius, Jerome, and other antient fathers, as having been written by him in the name of the church of Rome to that of Corinth, and which was often read in the time of Eusebius in the churches, after the gospels, on account of the excellent precepts which it contains. Eusebius (*Hist. Ec.* iii. 13) says that Clement succeeded Anencletus, or Anacletus, in the twelfth year of Domitian (A.D. 92), and that he died in the third year of Trajan (A.D. 100), having been bishop nine years. After mentioning his epistle to the Corinthians, Eusebius says that another epistle was also ascribed to him by some, but was not generally received as genuine; and that 'there had been published not long since other large and prolix works in his name, containing dialogues of Peter and Apion, of which the antients had not made the least mention.' Eusebius wrote at the beginning of the fourth century; and Jerome, who lived half a century later, repeats and confirms the remark of Eusebius. The first epistle of Clement, which was written in the name of the church at Rome to that of Corinth, 'Dei Ecclesia quæ Romæ peregrinatur Ecclesiæ Dei quæ Corinthi peregrinatur,' and was occasioned by a schism which had broken out at Corinth among the Christians, is full of sound and charitable advice. It consists of fifty-nine chapters, and is one of the most interesting memorials of the primitive church. The second epistle, supposed also to be Clement's, is only a fragment, containing likewise moral and religious advice; but it breaks off abruptly in the middle of the twelfth chapter, and there is no evidence of its being written to the Corinthians. It is supposed to be a fragment of some other work, but whether by Clement or by some subsequent writer is uncertain. Both epistles were found at the end of the New Testament in a MS. brought from Alexandria, and were published by Patrick Junius: 'Sancti Clementis Romani ad Corinthios Epistolæ duæ expressæ ad fidem MS. Cod. Alexandrini,' Oxford, 1633; and again by H. Wootton, Cambridge, 1718. Baratier and others argue from some passages in the first epistle, that Clement wrote it before the destruction of Jerusalem by the Romans, about A.D. 67 or 68, and probably before he became bishop of Rome, though some chronologists place his pontificate about that date; but the authority of Irenæus, Eusebius, and the other old fathers, seems to be the safest on such matters. A long account of Clement's life, pilgrimages, and martyrdom, has been made out by Gregory of Tours, Nicephorus, and others, entitled 'Acta S. Clementis,' and adopted by Baronius; but it is considered doubtful, even by most orthodox Catholics. It is not quite certain that Clement suffered martyrdom. He is said by some to have been exiled from Rome, and to have died in the Chersonesus Taurica; but this is also contested by others, and apparently with sufficient reason. (Nath. Lardner, *Credibility of the Gospel History*, vol. i. part ii ch. 2.) Clement was succeeded in the see of Rome by Evaristus. Several other works have been attributed to Clement, which are evidently apocryphal, such as eight books of Institutiones or Constitutiones, &c. (Tillemont, *Mémoires pour l'Hist. de l'Eglise*, vol. II.; Du Pin, *Bibl. des Auteurs Eccles.*) Wetstein published two more epistles attributed to Clement, which he found at the end of a Syriac version of the New Testament· they are chiefly in praise of virginity, and are considered as spurious. (Venema, *Epistola ad P. Wesseling qua duas Clementis Epistolas a C. Wetstenio ad calcem Novi Testamenti nuper publicatas, Epiphanio ac Hieronymo notas fuisse in dubium vocatur*, &c., Harlingen, 1754; and Wetstein's *Reply to Venema*, Amsterdam, 1754; also Nath. Lardner's *Dissertation upon two new Epistles, ascribed to Clement of Rome*, Lond., 1753.)

One of the oldest churches at Rome on the Cælian Mount is dedicated to St. Clement; but it is not quite certain whether it was built in honour of the bishop, or of Flavius Clement, the martyr, with whom the other has been often confounded. Flavius Clement was cousin to Domitian, and his colleague in the consulship (A.D. 95), and was put to death by order of that emperor on a charge of impiety towards the gods, which is understood to mean that he belonged to the Christian communion. His wife, Domitilla, was exiled on the same charge to Pandataria. Flavius Clemens is numbered among the martyrs by the earliest ecclesiastical historians. The old church, which is believed to have been built in the fifth century, fell to ruins, and was taken down by Adrian I. towards the end of the eighth century, and rebuilt by Nicholas I. in the ninth. In the year 1725, Cardinal Annibale Albani having made excavations under the great altar of St. Clement's, found a tomb with an inscription to Flavius Clemens, martyr. A full account of it with a dissertation was published: *Titi Flavii Clementis Viri Consularis et Martyris Tumulus illustratus*, Urbino, 1727.

CLEMENT II., Suidger, bishop of Bamberg, succeeded Gregory VI. in the papal chair in 1046, and after crowning the emperor, Henry III., died the following year, and was succeeded first by Benedict IX., who had been previously deposed by the council of Satri, and who was again obliged to abdicate, and lastly by Damasus II.

CLEMENT III., a native of Rome, succeeded Gregory VIII. in 1188. He summoned a crusade against the Saracens, in which the emperor, Frederick I., Richard of England, and Philip of France, embarked. He died after little more than three years' pontificate in 1191. He was succeeded by Celestine III.

There was also an antipope, or competitor, of the celebrated Gregory VII., who assumed the name of Clement III. from 1080 to 1101, but he is not numbered among the legitimate popes.

CLEMENT IV., a native of St. Gilles, in Languedoc, succeeded Urban IV. in 1265. He showed the same inflexible hostility as his predecessor against the Suabian dynasty of Naples, and assisted Charles of Anjou in the conquest of that kingdom, which was accomplished by the defeat and death of Manfred at the battle of La Grandella, near Benevento. Charles, in return, acknowledged himself at his coronation as feudatory of the see of Rome, and agreed to pay tribute. Conradin, Manfred's nephew, having attempted to reconquer his hereditary kingdom, was defeated by Charles at Tagliacozzo, and beheaded in the market-place at Naples, with the approbation of Clement, as it was reported. A month after Conradin's execution, Clement himself died, in November, 1268. His death was followed by an interregnum of about two years, after which the Cardinals at last elected Gregory X.

CLEMENT V., a Frenchman, and archbishop of Bordeaux, succeeded Benedict XI. in 1305, by the influence of Philip le Bel, who induced him to remove the papal residence to France. Clement joined Philip in suppressing the order of the Templars, and in condemning the grand master and sixty knights to be burnt alive. Clement died in April, 1314, and was succeeded, after two years interregnum, by John XXII. [CLEMENTINES.]

CLEMENT VI., a Frenchman, succeeded Benedict XII. in 1342. He resided at Avignon like his immediate predecessors, and it was under his pontificate that Rienzi made the attempt to re-establish the republic at Rome. [RIENZI.] Clement took the part of Joanna I., queen of Naples, against her brother-in-law, Lewis of Hungary, who had invaded her dominions to avenge the murder of [illegible]. Joanna, on her part, sold or gave away to [illegible] the town and county of Avignon, which [illegible] her as sovereign of Provence. Clement fixed the jubilee to be held at Rome every fifty years. He died in 1352, and was succeeded by Innocent VI.

CLEMENT VII., Giulio de' Medici, the natural son of Giuliano de' Medici, and nephew to Lorenzo the Magnificent, was made cardinal by his cousin, Leo X., and was afterwards promoted, in 1523, to the papal chair, then vacant by the death of Adrian VI. His pontificate was full of vicissitudes and calamities to Italy. He first allied himself with Francis I. against Charles V., in order to prevent the latter possessing himself of all Italy; but he only hastened the progress of the imperial arms, and saw his own capital, Rome, stormed and cruelly pillaged by the army of Charles, and himself besieged in the Castle Sant' Angelo. He afterwards made peace with the emperor, and united with him to destroy the independence of Florence, his native country. Clement's quarrel with Henry VIII. of England, which arose from his refusing the bull of divorce between that king and Catharine of Aragon, led to the schism between Henry and Rome. He died in 1534 after a long illness, leaving behind him a character stained by avarice, harshness, and deception; he had most of the failings, but none of the splendid or amiable qualities, of his cousin, Leo X. He was succeeded by Paul III.

There was also an antipope in the fourteenth century, who was elected by a party among the cardinals in opposition to Urban VI., and who assumed the name of Clement VII. The schism lasted many years, and was continued by the respective successors of Urban and of Clement till the Council of Constance decided the question. The Roman calendar acknowledges Urban and his successors as legitimate popes, and places Clement among the antipopes. [URBAN VI. and BENEDICT ANTIPOPE.]

CLEMENT VIII., Ippolito Aldobrandini, succeeded Innocent IX. in 1592. He was a man of learning, and of considerable political sagacity. He succeeded in the negotiations with Henry IV. of France, by which that prince made public profession of Catholicism, and was acknowledged king by his subjects. Clement annexed, by force, the duchy of Ferrara to the papal state after the death of Duke Alfonso II., disregarding the claims of the Duke's cousin, Cesare d'Este, who was obliged to yield, and retire to Modena. Clement died in February, 1605, and was succeeded by Leo XI. He published a new edition of the Vulgate, differing in some particulars from that published under Sixtus V., in 1590. He also issued many bulls, the most remarkable of which are the 28th, defining the lawful and unlawful rites and usages of the Greek church, and the 87th, concerning the practice of confession and absolution in writing.

CLEMENT IX., Giulio Rospigliosi, of a noble family of Pistoia, succeeded Alexander VII. in June, 1667. He showed a wise conciliatory spirit, hushed for awhile the controversy between the Jansenists and the Jesuits [ARNAULD], and settled the long-pending dispute between the see of Rome and the king of Portugal, on the right of nomination to the vacant bishoprics, by confirming the prelates appointed by King Pedro II. He took a warm interest in the war between Venice and the Turks, and sent assistance of men and money to the Venetians for the defence of Dalmatia and of Candia. The news of the loss of that island, which was finally conquered by the Turks in 1669, is said to have hastened the death of Clement, which occurred in December of that year. He was much regretted by his subjects as well as by foreign princes. He embellished Rome, and was magnificent in his expenditure. His nephew was made a Roman prince, and married the heiress of the house of Pallavicini, of Genoa. Clement IX. was succeeded by

CLEMENT X., Emilio Altieri, who was 80 years of age at the time of his election, in 1670. He intrusted the affairs of the administration chiefly to Cardinal Paluzzi, a distant relative, whom he adopted as his nephew, and gave him his family name of Altieri, as he had no nearer relations living. He died in 1676, and was succeeded by Innocent XI.

CLEMENT XI., Gian Francesco Albani, succeeded Innocent XII. in November, 1700. He was then fifty-one years of age, had been made a cardinal by Alexander VIII., and had a merited reputation for learning and general information. He was one of the men of letters who frequented the society of Christina of Sweden during her residence at Rome. It was with seeming repugnance, and after several days' hesitation, that he accepted the papal dignity. The war of the Spanish succession was then just breaking out, and Clement in vain exerted all his powers of persuasion with the courts of France and of Austria to prevent the impending calamity. Louis XIV. having placed his grandson Philip on the throne of Spain, demanded for him of the pope the investiture of the kingdoms of Naples and Sicily, whilst the emperor claimed it likewise as his right. Clement delayed giving his decision, and the intrigues of the agents of the two rival powers disturbed the peace of his own capital. In 1707 the Austrians, under Marshal Daun, traversed the papal state to proceed to the conquest of Naples; and the pope, unable to prevent them, stipulated only that they should not pass through the city of Rome. In the following year the pope came to an open rupture with the emperor, Joseph I., whose troops had taken possession of Comacchio in the papal state. After trying remonstrances in vain, Clement collected an army of 25,000 men, under the command of Count Marsigli; but the papal troops retreated before the Austrians, who occupied Romagna and the Marches, and the pope was obliged to sue for peace, which the emperor readily granted in January, 1709. Comacchio was ultimately restored to the pope.

About the same time a large volume was written by Clement's directions, concerning the claims of the see of Rome upon the duchies of Parma and Piacenza, which the emperor considered as feudatory to the empire, and had accordingly stopped the remittances to Rome of the fees and revenues claimed by the papal see from the ecclesiastical benefices in Lombardy, and other countries subject to the House of Austria. Clement was tenacious of what he considered as the prerogatives of his see over the clergy of other countries, and he quarrelled in 1715 with the House of Savoy, which then ruled over Sicily, about a tribunal in that island, called di Monarchia, which interfered with the ecclesiastical immunities and the alleged rights of Rome over Naples and Sicily, as fiefs of the papal see. The king, Victor Amadeus II., stood firm; and many of the Sicilian clergy, who refused to obey the directions of the tribunal, were either imprisoned or obliged to emigrate. About four hundred of the latter took refuge at Rome. Clement had also long and serious disputes with France. He began by his bull 'Vineam Domini,' renewing the interdict which his predecessors had issued against the Jansenists, and declaring their propositions about grace and free will to be heretical. In 1713 he issued the famous bull 'Unigenitus,' which set the whole kingdom of France, court, parliament, and clergy, in an uproar. This bull condemned 101 propositions of a book by Father Quesnel, entitled 'Moral Reflections on the New Testament;' in which that writer revived several opinions of St. Augustin, St. Prosper, and other old fathers, which sounded favourable to the Jansenistic dogmas of predestination and grace. The Jesuits, who asserted that grace was subordinate to the will of man, and who were accused by the Jansenists of Pelagian heresy, stirred themselves to have Quesnel's book condemned. Several French prelates, Bossuet and Cardinal Noailles among others, approved of the general tenor of Quesnel's book, which contains much sound moral doctrine. Cardinal Noailles had already indisposed the pope against him by presiding at an assembly of the French clergy in 1705, in which the bishops were declared to be judges in matters of doctrine, independent of the pretensions of the popes, who would reduce them to the condition of mere registrars and executors of the papal decrees. Father le Tellier, a Jesuit and confessor to Louis XIV., urged the king in favour of the bull 'Unigenitus,' which was at last registered by the parliament of Paris, after much opposition, and continued for years after to keep up a sort of schism between France and Rome. Father Quesnel, the involuntary cause of all this disturbance, died in December, 1719, at Amsterdam, where he had taken refuge. In a declaration which he signed before a notary he professed that he died in the bosom of the Roman Catholic church, appealing to a future council against the bull 'Unigenitus.'

Another source of tribulation to Clement proceeded from the disputes concerning the Jesuit missionaries in China, who had gained considerable influence at the court of Pekin, and were accused by the other missionaries of latitudinarianism, of winking at several superstitious practices in order to make proselytes, and of even countenancing idolatry. Clement sent, in 1702, Cardinal de Tournon as legate to China; but the cardinal on arriving at Macao was so worried by the angry controversialists that he died of anxiety and disappointment, and the quarrel between the missionaries continued to rage more furiously than ever, to the great scandal of the Chinese. Clement at last issued a constitution, or series of ordinances, by which he regulated the course to be followed by missionaries in making proselytes: it was sent in a circular to the superiors of the different monastic orders who had missionaries in China. As the quarrel however continued to rage in China, Clement sent the prelate Mezzabarba as his legate. Mezzabarba went to Pekin, where he was coldly received by the emperor, who was said to be prepossessed against him by the Jesuits, and the legate was soon dismissed from the celestial empire.

Clement took a warm interest in the expedition of the Pretender, son of James II., in 1715, and furnished him with money. After the failure of that attempt, the Pretender, being forsaken by France, retired to Italy under the name of the Chevalier de St. George, and Clement appointed the town of Urbino for his residence. He afterwards negotiated his marriage with Clementina Sobieski, which was celebrated at Monte Fiascone, at the pope's expense, who gave to the married couple a palace at Rome to reside in, with an annual pension of 12,000 crowns. The court of Rome did not for a long time after give up its favourite scheme of regaining England to Catholicism, by means of the Stuarts.

Clement was more profitably employed in frustrating the schemes of the Turks, who, having invaded the island of Corfu in 1716, were threatening Italy with an invasion. The pope sent a squadron to join the Venetians, he levied a contribution upon the clergy of all Italy to defray the expense of the war, and he prevailed on the emperor, Charles VI., to join Venice against the Porte. This led to the brilliant campaign of Prince Eugene, who defeated the Turks at Peterwaradin, and took Temeswar. The Turks were also obliged to raise the siege of Corfu.

After the fall of the intriguing Alberoni, in 1719, Clement succeeded in settling his disputes with Philip V. of Spain, and his Nunzio was again received at Madrid. Europe was now at peace, and Clement enjoyed a short period of rest, after a long series of agitations, until March, 1721, when he died, after a pontificate of more than twenty years. In his private character he was amiable and generous, and his morals were irreproachable. He was very moderate in providing for his nephews, who owed their elevation more to his successors than to himself. He embellished Rome, and established the Calcografia Camerale, which has since given to the world many splendid engravings; he encouraged the art of mosaic, and he introduced at Rome the manufactory of tapestry, on the model of the Gobelins. He added to the Vatican library, and to the museum which is annexed to it. Grateful to the memory of his early patroness, Christina of Sweden, he raised to her a monument in St. Peter's. He patronised men of letters and of science, was the friend of Guidi, Menzini, Sergardi, Marsigli, Martelli, Zappi, and the learned Bianchini. A fine edition of his decretals, bulls, and constitutions, was published by his nephew, Cardinal Annibale Albani, after his death, 'Bullarium Clementis XI.,' one vol., fol. He wrote also several Latin homilies, which he recited on solemn festivals, and which were translated into Italian by Crescimbeni.

CLEMENT XII., Lorenzo Corsini, of Florence, succeeded Benedict, in July, 1730. He was then seventy-nine years of age, and infirm. He resumed the old contest with the empire about the reversion of the duchies of Parma and Piacenza, but succeeded no better than his predecessors. He endeavoured, and also in vain, to mediate in the war between the republic of Genoa and the Corsicans. He succeeded better in restoring, in 1740, the little republic of San Marino to its liberties, which had been encroached upon by Cardinal Alberoni. He died soon after, in 1740, and was succeeded by Benedict XIV.

CLEMENT XIII., Carlo Rezzonico, a native of Venice, succeeded Benedict XIV. in July, 1758. He was more distinguished for his piety and private virtues, than for political abilities or knowledge of the world. His pontificate was a continual, but on his part ineffectual, struggle to uphold the ecclesiastical immunities and the old prerogatives of the see of Rome against the determination of the other powers to be complete masters in their respective countries. He strove hard to support the Jesuits, who had become obnoxious to various courts, and who were suddenly suppressed in Portugal, Spain, France, and Naples. In their distress, most of the expelled fathers sought an asylum in the Papal States, and found in Clement a generous protector. All the remonstrances and threats of France and Spain could not induce him to abolish the Order, which he considered as the firmest support of the Roman see. The king of France seized upon Avignon, and the king of Naples upon Benevento; still the pope held firm till his death. The Venetian senate, by a series of decrees passed in September, 1768, enforced numerous reforms in ecclesiastical discipline in their own dominions, subjected the clergy to the payment of tithes, suppressed some convents, placed the rest under restrictions with regard to their property and the number of their inmates, and subjected all ecclesiastics to the jurisdiction of the secular courts in temporal matters. Clement strongly remonstrated against these innovations: he threatened excommunication, but the senate persisted in its resolutions. He also came to a rupture with the republic of Genoa, because he had sent an apostolic vicar into Corsica, which was then in a state of revolt against the Genoese. The elector of Bavaria, about the same time, declared that none but his own subjects should hold benefices within his dominions. Maria Theresa made similar enactments in her own states, and she took away the censorship of books from the ecclesiastical authorities, and gave it to the secular magistrates. Tuscany, Parma, and Naples suppressed convents, and checked the practice of donations and legacies to the church. In the midst of all these blows against the papal authority, Clement died in February, 1769. A splendid mausoleum was raised to him by Pius VI. in St. Peter's church, which is much admired, especially for its statue of the pope kneeling at prayers, and the two lions couching at the foot of the monument. It was one of the earlier, and among the best, works of Canova, who was employed eight years upon it. It was finished and exposed to public view in the holy week of 1793.

CLEMENT XIV., Gian Vincenzo Ganganelli, was born at Sant' Angelo in Vado, near Rimini, in 1705. At an early age he entered the order of Franciscans, distinguished himself by his learning, was favourably noticed and employed by Benedict XIV., and was made a cardinal by Clement XIII., whom he succeeded in May, 1769, after a stormy conclave, which lasted two months. He adopted a conciliating tone towards the foreign powers, which at the death of his predecessor were on the eve of an open rupture with Rome. He discontinued the public reading of the bull in Cœna Domini, which was considered offensive to the sovereigns. The great question which at that time agitated the Roman Catholic world was the definitive abolition of the order of the Jesuits. Ganganelli took several years to decide on this important subject, and at last, on the 21st July, 1773, he issued the bull of suppression. But the manner in which that suppression was executed in the papal state partook of unnecessary rigour and harshness. Soon after this step, Clement, overcome by labour and anxiety, began to decline in health. About Easter, 1774, he was taken dangerously ill, under suspicious symptoms; he lingered a few months, and died 22nd September, 1774. Rumours were spread that he had died of poison, but the post mortem examination of his body and the report of the physicians did not countenance the suspicion. Ganganelli was a man of enlightened mind; perhaps too much so for the taste of the more violent zealots about the court of Rome. He had a taste for the arts; he continued the collection of antique sculptures begun by Lambertini, and ranged them in a suite of rooms in the Vatican, which was called the Clementine museum, and was afterwards greatly enlarged by his successor, Pius VI., when it received the name of Museo Pio-Clementino. He added also to the Vatican library. A fine monument, the work of Canova, was raised to him in the church of S. Apostoli, which belonged to a convent of his order. The letters published by Caraccioli under the name of Ganganelli are now generally understood to be apocryphal; although the writer has traced pretty faithfully the character and many of the sentiments of that distinguished pontiff. Ganganelli was simple in his habits, free from ambition, and not given to nepotism.

CLEMENTI, MU'ZIO, who is justly entitled to rank as the father of the piano-forte school, both as regards tion and performance, was born, in 1752, at Rome, s father practised as an embosser of silver figures for the service of the church. At nine years of age he had made so much progress in music under Cordicelli, that he passed a close examination, and was appointed to an organist's place in his native city. He afterwards studied under Santarelli and Carpani, and wrote a mass for four voices when in his thirteenth year. About that time his talents attracted the notice of Mr. Peter Beckford, an English gentleman, then travelling in Italy, who undertook the future education of the young artist, and brought him to his seat in Dorsetshire, where the society of a literary and accomplished family inspired him with that taste for the belles-lettres which encouraged him to pursue a course of study that had been well commenced under a member of the Society of Jesus, and to acquire an extensive knowledge of the learned and living languages, as well as of various branches of science. But he did not neglect the art which he had chosen as his profession, for before he had completed his eighteenth year he composed his celebrated Opera 2: 'a work which, in the opinion of all good musicians, is the basis on which the whole fabric of modern piano-forte sonatas has been founded.'

At the time agreed on by his father, Clementi quitted Mr. Beckford. He shortly after was engaged to preside at the harpsichord at the King's Theatre, and soon was actively and lucratively employed as a master of the first rank. In 1780 he made a tour on the continent, whither his fame had long preceded him, and enjoyed everywhere the highest patronage and the most flattering applause. In Vienna he made the acquaintance of Haydn, Mozart, &c., and played alternately with the latter before the Emperor Joseph II. and other royal personages. While in Paris he wrote his Operas 5 and 6; and in Vienna his Operas 7, 8, 9 and 10 were composed. On his return to England he published his Opera 11, and Toccata, as well as his Opera 12. In 1783, J. B. Cramer, who had previously studied under Abel and Schrœter, became his pupil, and attended him almost daily.

About the year 1800, having suffered considerably by the failure of the house of Longman and Broderip, he was, by the advice of some eminent mercantile friends, induced to take possession of the premises of those partners, to embark in the music-publishing and piano-forte manufacturing business, and become the head of a new firm, from which time he declined all pupils, and devoted himself wholly to his new, important, and successful occupation. But the peace of 1802 tempted him abroad again, and, accompanied by his pupil, Field, he proceeded from city to city till he reached St. Petersburg, where he made some stay. In Berlin he married, and with his bride proceeded to Rome and Naples. He shortly after lost his wife, in childbed of a son, who grew up to be his father's pride and solace, but unhappily lost his life by the accidental discharge of his own pistol. In 1810 Mr. Clementi, after encountering many difficulties in his attempts to reach England during the fiercest period of the renewed war, arrived in London, and shortly after entered again into the married state. During his last visit to the continent he published his Opera 41, and collected materials for many other works, which subsequently appeared, among which his *Practical Harmony* in four volumes, and his *Gradus ad Parnassum*, in three, must not be left unnoticed.

In 1813 Mr. Clementi assisted in founding the Philharmonic Society, of which he frequently consented to act as a director, and presented to it his two symphonies, which were more than once performed by that admirable band, and received with every mark of respect. They both abound in agreeable melody, and are most skilfully written; but the real vigour of the composer's genius is exhibited in his piano-forte works, which will be revived or laid aside as true taste shall happen to be in the ascendant or on the decline.

After an illness of no long duration, Mr. Clementi died on the 10th of March, 1832. His remains were deposited in the cloisters of Westminster Abbey, and attended to the grave by the choir of that church, of the King's chapel, and of St. Paul's, together with numerous friends. In the *Harmonicon* for April, 1832, is a just eulogy of this very celebrated composer, by a brother-member of the Philharmonic Society, who thus speaks of him:—'He was honourable in his intercourse with the world, affectionate and attentive to his family, constant in his friendships, and benevolent in his feelings towards the whole human race.

CLEMENTINES is the name given to a collection of decretals and constitutions of Pope Clement V., which was published in 1308 under the title of 'Liber septimus Decretalium,' being the seventh book in order of time of the collection of the decisions and rescripts of the popes on matters of ecclesiastical discipline, and also on matters concerning laymen which then came within the cognizance of the ecclesiastical courts. [CANON LAW.] The first printed editions of the Clementines are those of Mainz, 1460 and 1467, fol., which are very scarce.

CLEODO'RA. [HYALÆIDÆ.]

CLEO'MBROTUS I., brother of Agesipolis, succeeded him as king of Sparta. In 378 B.C. he marched with an army into Bœotia to attack the Thebans. Passing into the Theban territory he encamped at Cynoscephalæ, and, after remaining there sixteen days, withdrew to Thespiæ. The purpose of the expedition not requiring his presence longer, he left a third of his forces under Sphodrias, and led back the rest to the Peloponnesus. Two years afterwards, 376 B.C., in consequence of the severe illness of Agesilaus, he was chosen to lead another army against the Thebans. In 371 B.C. he commanded, in the celebrated battle at Leuctra, against Epaminondas. The Lacedæmonian horse were quickly routed and were immediately charged by the Theban phalanx. Cleombrotus was mortally wounded in the attack, and died soon after. (Xenophon, *Hellen.* v. 4, vi. 4.)

CLEOMBROTUS II., son-in-law of Leonidas, was elected king of Sparta on the expulsion of Leonidas. (Pausanias iii. 6; Clinton, *Fast. Hel.*, p. 217.)

CLEOME'DES, a Greek writer on astronomy. There is some doubt about the age in which he lived; or, which is the same thing, whether the manuscripts remaining which bear the name of Cleomedes were all written by one man, or by two men at different times. The manuscripts which remain are on astronomy, on the doctrine of the sphere, and on arithmetic. Vossius conjectures that the work on music attributed to Cleonidas belongs to Cleomedes. Riccioli seems to have been one of the first who supposed that there were two of this name, one about the time of Augustus, the other in the reign of Theodosius. The work on astronomy was attributed by Vossius to the latter; but the principal arguments against so late an author lie in his frequent mention of Pythagoras, Eratosthenes, Hipparchus, and Posidonius, and his entire silence about Ptolemy. See however the arguments of Letronne, *Journal des Savans*, 1821, p. 713.

We mean by Cleomedes the one of that name who wrote the work Περί κυκλικῆς ϑεωρίας μετεώρων, in two books, On the Circular Theory of the Heavenly Bodies. It is professedly in several parts taken from a writing, or from the public lectures, of Posidonius, who was certainly the contemporary of Cicero. It is a probable conjecture that Cleomedes was a pupil of Posidonius. The work in question has considerable historical value it records the measures of the earth by Posidonius and Eratosthenes, establishes the antiquity of the opinion that the rotation of the moon is equal to her synodical revolution round the earth;—had it been the sidereal revolution, it would have been correct. It gives various arguments in proof of the rotundity of the earth, in opposition to the supposition of flat and cubical forms, &c., and from this source the early English writers drew much of what they said on the same subject. It mentions eclipses as having happened without having been predicted in the 'canons;' a proof that something answering to an almanac was in common use. It decidedly suggests the possibility of rays of light being bent by the air. Delambre has made it sufficiently apparent that Cleomedes was not acquainted with the writings of Hipparchus, though he frequently cites opinions and methods which he attributes to him.

The earlier editions of Cleomedes are, 1. The Latin version of George Valla, Venice, 1497 or 1498. 2. In Latin, with Aristotle and Philo, Basle, 1533. 3. The first Greek edition, by Conrad Neobarius, Paris, 1539. 4. In Greek and Latin with Aratus, Proclus, and Dionysius, Basle, 1547; again in 1561; again in 1585. 5. In Greek and Latin, with a Commentary, by George Balfour, Bordeaux, 4to., 1605. This edition was re-published with additional notes, by Janus Bake, Leipzig, 1820; this also was re-published, with additional notes, by C. C. Theoph. Schmidt, Leipzig, 1831. The most esteemed manuscript is that in the public library at Wittenberg. (Riccioli, Vossius, Weidler, Heilbronner, Delambre, *Hist. Astr. Anc.* i. 218.)

CLEO'MENES, the name of several kings of Sparta. Cleomenes I., son of Anaxandrides (Herod. v. 39), although not perfectly sane, succeeded his father. (Herod. v. 42.) He expelled the Peisistratidæ from Athens (Herod. v. 63. 64), 510 B.C., and espoused the cause of Isagoras in opposition to Cleisthenes [CLEISTHENES], who, however, with the seven hundred families that had been banished, afterwards returned and forced him to leave the city. Demaratus, the colleague of Cleomenes, accused him of favouring the Medes, while on an expedition against the Æginetæ, and obliged him to return home. By the aid of Leotychides, a private enemy of Demaratus, and by bribery of the Delphic oracle, Cleomenes succeeded in effecting the abdication of Demaratus. (Herod. vi., 65, 66.) In a war against the people of Argos (about 491 B.C., Clinton, *Fast. Hel.*, p. 425, *note* x.), Cleomenes was completely victorious, and burnt a great number of the fugitives in a sacred grove where they had taken refuge. (Herod. vi., 80.) The means by which he had contrived to get rid of Demaratus afterwards becoming known, he was banished into Thessaly and subsequently to Arcadia, where he endeavoured to stir up the people against the Lacedæmonians. (Herod. vi., 74.) He was ordered to return, and on his arrival in Sparta he confirmed the belief of his madness by mortally wounding himself (Herod. vi., 75), 492 B.C.

CLEO'MENES II. succeeded his brother Agesipolis II. (Diodor. Sic. xv., 60), 309 B.C., and reigned 61 years: he died 370 B.C. (Clinton, *Fast. Hel.*, pp. 205, 213).

CLEO'MENES III. succeeded his father Leonidas on the throne of Sparta B. C. 236. Immediately on his accession he set himself to oppose Aratus and the Achæans, who were endeavouring to draw all the Peloponnesians into their league. [ACHÆI.] The Ephori were averse to the war, and Cleomenes saw no way to attain his ends but by abolishing their power. Accordingly he put four of them to death, and attempted to excuse this act of violence by showing the necessity of restoring the antient institutions of Lycurgus, which could not be effected by any other means. He renewed the old Spartan system of education, and himself observed great simplicity in his mode of life. His colleague of the house of Proclus, an infant, whose name was Eurydamidas, he also removed out of the way by poison, and shared the kingly power with his own brother Eucleidas (Pausanias, 2, 9). He also abolished the Gerusia (γερουσία), or senate, and transferred their powers to another body (patrónomi) apparently of his own creating; but this rests solely on the authority of Pausanias. Cleomenes, in his invasion of Achæa, took several cities, and soon afterwards attacked Argos. In order more effectually to oppose Aratus, who had obtained the assistance of Antigonus, Cleomenes formed an alliance with Ptolemy, king of Egypt. The contending parties fought a decisive battle at Sellasia, in Laconica, in which the Lacedæmonians were completely defeated: of 6000 men only 200 survived. After the battle Cleomenes fled to Egypt, where he was hospitably entertained by Ptolemy Evergetes. His son and successor however, Ptolemy Philopator, soon showed considerable jealousy of the royal guest, and accordingly put him in confinement. Cleomenes killed himself in the third year after his flight, and his body was afterwards nailed upon a cross by Ptolemy Philopator, B. C. 220 (Clinton, *F. H.*, p. 205). He reigned sixteen years. (Plutarch, *Cleom.*, c. 38.) Livy (xxxiv. 26), following Polybius (iv.), represents Cleomenes as a tyrant; but Polybius was a native of a city (Megalopolis) which Cleomenes had destroyed, and the support of the Achæan league was a family concern. The truth appears to be, that the great object of Cleomenes was to revive the antient discipline and institutions of Lycurgus, and to put an end to the luxury and corruption which had crept into the state. If the means which he took were sometimes indefensible, it may perhaps be said in reply that his ends were good, and that such means were not entirely condemned by the positive morality of his age and country. (Polybius, ii. iv. and v.; Plutarch, *Life of Cleomenes.*)

CLEON, of Athens, the son of Cleaenetus, was originally a tanner. Early in life he began to take an active part in the political affairs of Athens, and his success seems to have drawn him from his business. He set himself up as the champion of the people, and was especially vehement in their cause, when their interests appeared to be opposed to those of the rich. The first affair in which he took a prominent part was the discussion on the massacre of the Mitylenæan prisoners, 427 B.C., who were sent to Athens after the reduction of the island by Paches. Such was the influence of Cleon on this occasion that he succeeded in persuading the assembly to pass a decree, by which all the Mitylenæan prisoners sent to Athens by Paches, and every citizen in Mitylene, should be put to death, and the women and children made slaves. The prisoners, who had been sent to Athens, were massacred the same day to the number of more than one thousand; but the timely remorse of the Athenians prevented the execution of the remainder of the sentence. In an assembly called on the following day to reconsider the decree, Cleon came forward to support it with the utmost vehemence, and the majority of his opponent Diodotus was very small.

In 425 B.C., the Athenians built a small fort at Pylos, in Messenia, under the direction of their general, Demosthenes. The Lacedæmonians, with the view of destroying a post that would prove a great annoyance to them, made preparations to besiege it, and also threw a body of men into the small island of Sphacteria, which lay at the entrance of the harbour of Pylos. The island was immediately blockaded by the Athenians; but as there seemed no prospect of its being speedily taken, the Athenians at home began to complain, and Cleon accused the generals of want of activity in pressing the blockade. 'If he were in command,' he said, 'he would soon finish the business.' The people took him at his word; Nicias, one of the commanders at Pylos, insisted that Cleon should supersede him, and the demagogue, much against his will, was obliged to accept the command. However, he put the best face on the matter, and said that he would be back at Athens in twenty days, and would either bring with him all the Lacedæmonians in the island prisoners, or he would not leave a man of them alive. He took Demosthenes as his colleague in the expedition. He was as good as his word, and brought the Lacedæmonians prisoners to Athens within the twenty days. Thucydides, who rarely indulges in reflections on the character of persons in the body of his history, could not abstain from a side-blow at this odious demagogue. The most sensible among the Athenians, he observes, were rather pleased at Cleon's being intrusted with the affair of Pylos, for they thought that the result in any event could not be otherwise than good: they would either get rid of Cleon for ever, which they rather expected, or, if they were disappointed in this, he would probably take the place.

Whether any of the merit of this exploit belonged to Cleon seems more than doubtful. (Aristoph. *Equ.* 54, &c.) His prudence in the selection of his colleague cannot be questioned. The reputation which he gained for energy and promptitude in this affair, added to his inordinate vanity, completely turned his head, and it would seem by what followed as if many of his countrymen were so far deceived by this lucky business of Pylos as to think that Cleon actually had the talents that he pretended to. Accordingly, in 422 B.C. this incapable babbler was fixed upon as the proper person to oppose the movements of the able Spartan general Brasidas in Macedonia and Thrace, and he received the undivided command of 1200 heavy-armed men and 300 horse, with still larger forces of Imbrians and Lemnians, and a fleet of 30 galleys. He did not march direct to Amphipolis, which was the principal object of the expedition, but stopped in his way to recover Torone. Brasidas, who had left the town, had stationed there a garrison which was inadequate for its defence, and accordingly Cleon was successful in his attack on the place. He sold all the women and children as slaves, and sent more than 700 men as prisoners to Athens. Proceeding with increased confidence in his own military powers, he stationed himself at Eion on the Strymon, and delayed the attack on Amphipolis till he had received reinforcements. During this interval he made a fruitless attempt on Stagirus, but succeeded in his attack on Galepsus. The murmurs of his soldiers, who from the first had not been pleased with Cleon's being appointed to the command, soon induced him to move towards Amphipolis with a view of reconnoitring, but not of fighting. Brasidas, however, who was in Amphipolis, did not choose to let him off so easily: he made a sudden sally out of the place, while Cleon, who was quite unprepared for an attack, and had not the least intention to fight, was giving orders for a retreat. In the battle that ensued both the Lacedæmonian and the Athenian generals fell B.C. 422. Cleon, says Thucydides (with a half malicious coolness), who had never had any idea of keeping his ground from the first, was caught as he ran away, and killed by a Myrcinian targeteer. The remains of the Athenian army returned home.

If Cleon possessed any qualifications at all as a statesman, they consisted not in superiority of talent or in political knowledge (for he had little of either), but in a singular facility of speaking and a great command of words, which, combined with low manners, unsparing abuse of those who were better than himself, and a coarse vehement mode of delivery, rendered him acceptable to the mob. Whatever influence he gained with the more considerate citizens seems to have arisen from the reputation which he gained for blunt honesty in the declaration of his sentiments, and a general promptness in action. The real qualities which he contrived to get so favourably interpreted appear to have been impudence and rashness. The indignation of the comic poet (Aristophanes) was at last roused to endeavour to suppress what seemed to defy all other opposition. Aristophanes levelled at Cleon the shafts of his satire, and held him up to public ridicule in the most ridiculous colours. On one occasion (in the *Acharnenses*), alluding to the demagogue's former occupation, he threatens to 'cut him into shoe-leather,' and the comedy of 'the Knights' (Ἱππῆς) was composed with the express object of destroying his authority, which had been raised to so extraordinary a pitch by his success in the affair of Pylos. The victory at Sphacteria took place 425 B.C., and 'the Knights' was represented 424 B.C. Such was the dread of offending Cleon, that not an actor was to be found bold enough to personate him on the stage, while the mask-maker refused to give a representation of his face, and Aristophanes was obliged to act in that character himself, supplying the want of a mask by smearing his face with the lees of wine. [BRASIDAS; ARISTOPHANES.] (Thucyd. iii., 36; iv., 21-40, &c.; v., 2-10; Aristoph., *Equites*; Thirlwall's *Greece*, vol. iii., pp. 185-192, 244-251, 300-304.)

CLEO'NUS, a genus of Coleopterous insects, of the section Rhyncophora, and family Curculionidæ.*

Technical characters:—antennæ rather short, the scape not touching the eyes; basal joint of the funiculus nearly obconic, and rather longer than the remaining joints; the joints from the second to the sixth short and coarctate, the seventh stouter, and closely applied to the club, which is oblong-ovate or nearly so; rostrum short and thick, having generally a channel above; eyes oblong and depressed; thorax subconic, slightly constricted anteriorly; elytra elongate, generally furnished with a protuberance near the apex, which is rounded; legs nearly equal; femora unarmed; tibiæ with the apex slightly thickened, and furnished with a short spine.

Of the genus Cleonus about a hundred species are known; they inhabit Europe, Asia, and Africa. The ground colour of their body is almost always black, but this is for the most part hidden by the denseness of the little scales with which they are covered. These scales are generally of an ash-like colour, grey, white, or pale-brown, and small patches of two or more of these tints form clouded markings. Dark markings are often produced by the want of these scales on certain parts, the ground colour of the body then showing itself.

Cleonus sulcirostris is given as the type of this genus. We will therefore describe it. It is about two-thirds of an inch in length, of an elongate oval form, and of an ashy or white colour; the rostrum is thick, nearly as long as the thorax, and furnished with three deep longitudinal furrows; the thorax is almost as wide as the elytra at the base, and tapers towards the head; there is a longitudinal pale line in the centre, which is bordered by two broad dark brown patches; the rest of the thorax is pale, with the exception of a small brown patch on each side; the elytra are of an ashy colour, and have two oblique V-shaped fasciæ near the middle.

This insect is common in various parts of England, and seems more particularly to frequent chalky and sandy situations; it is sometimes found on nettles and thistles, and often crawling on barren sand-hills near the sea-side. Three or four other species are also found in this country. *Cleonus nebulosus* is very common in some parts of Hampshire, and nearly resembles the one above described, but may be at once distinguished by the absence of the sulci on the snout or rostrum: the scales in this species are not unfrequently red.

CLEOPA'TRA (Κλεοπάτρα), a daughter of Ptolemy

---

* Among the various modes of dividing the immense group of insects called Rhyncophora by Latreille, Curculionidum by Schonherr, and Curculionidæ by Leach, it is difficult to choose which to adopt. It is necessary to state, that the term Curculionidæ is here restricted to that group of the Rhyncophora included under the head Curculio proper by Latreille.

Auletes, king of Egypt, was born about B.C. 69 Her father, who died B.C. 51, left two sons called Ptolemy, besides Cleopatra and her sister Arsinoe. By her father's will Cleopatra and her elder brother were to be joint sovereigns, but they soon disagreed, and Cleopatra was obliged to take refuge in Syria. In B.C. 48, Julius Cæsar arriving in Egypt in pursuit of Pompey, who had fled from the battle of Pharsalia, determined to carry the will of Ptolemy into effect, and to settle the dispute between Cleopatra and her brother. The youthful queen, who probably knew the character of the Dictator, contrived to get herself privately conveyed into his presence, and by her fascinating manners completely gained his favour. Though not remarkable for beauty, according to the testimony of antient writers, which is confirmed by her medals, she possessed great natural abilities, which had been carefully cultivated. She is said to have spoken with facility several languages, besides her native Greek; a circumstance in itself well calculated to give an artful woman a great ascendency over all with whom she came in contact. Cæsar decided that Cleopatra should be restored to her equal share of power. This decision giving dissatisfaction to the young prince and his advisers, led to an attack upon Cæsar's quarters under Achillas, the commander of the king's troops. After a blockade of some months Cæsar received reinforcements, and completely defeated the party of the king, who was drowned in the Nile. The sovereign power was now given by Cæsar, in conformity with the meaning of Ptolemy's will, to Cleopatra and her younger brother Ptolemy. On Cæsar's return to Rome, Cleopatra shortly after followed him, and remained there till his assassination (B. C. 44), when she hastily quitted the city and returned to Egypt. (Cic. *Ep. ad Att.* xiv. 8.)

In the fourth year of their joint reign Cleopatra murdered her brother Ptolemy. Her connexion with Marc Antony commenced after the battle of Philippi, about B. C. 40, with the interview at Tarsus in Cilicia, of which Plutarch (*Anton.* 25—27) has given a minute description, and which Shakspeare, in his play of 'Antony and Cleopatra,' has turned into a glowing picture. Antony had no doubt seen Cleopatra during her residence at Rome, but, according to Appian, he was first struck with her charms in Egypt (B. C. 55) when he accompanied Gabinius, who was commissioned to restore Ptolemy Auletes to his throne. Cleopatra at this their first interview was only in her fifteenth year. From the time of the meeting at Tarsus the destinies of Antony and Cleopatra were united. The voluptuous queen, whose love of pleasure was unbounded, found in Antony a companion to her taste; and she spared no pains to attract him by all the allurements that her inventive talents could devise. Her influence over him seems to have continued undiminished to the end of his life.

If we may believe the extant authorities, Antony was even prevailed upon by Cleopatra to order her sister Arsinoe to be put to death, who had taken sanctuary in the temple of Diana at Ephesus.

The return of Antony to Italy, and his marriage with Octavia, the half-sister of Octavianus, for a time separated him from the queen of Egypt; but they met again in Syria (B.C. 36) previous to the unsuccessful Parthian expedition of that year, after which Antony renounced his wife for the charms of Cleopatra. Cleopatra was present at the decisive battle of Actium, and set the example of flight, which was followed by Antony. On the death of Antony Cleopatra committed suicide in order to avoid the humiliation of being led in the triumphal procession of Octavianus. Most probably she took poison. According to the story in Plutarch, she was closely watched by the orders of Octavianus, who suspected her designs, but she procured a poisonous serpent to be introduced in a basket of figs. The queen, after using the bath, and partaking of a sumptuous repast, applied the deadly serpent to her arm. Two of her female attendants died with her. The emissaries of Augustus, who had received a letter from Cleopatra declaring her intention, came too late to save her for a Roman triumph. They found her body lying on a golden couch in her royal robes, with one of her attendants dead by her side, and the other with just strength enough remaining to fix the diadem on the head of her mistress. Cleopatra at the time of her death was in her thirty-ninth year. She was buried by order of Octavianus with royal honours in the same tomb with Antony. With Cleopatra ended (B. C. 30) the dynasty of the Greek kings of Egypt, which commenced with Ptolemy, the son of Lagus, B. C. 323.

She had by Julius Cæsar a son, Cæsarion, who was put to death by Octavianus. By Antony she had three children, Alexander, Ptolemy, and Cleopatra, all of whom adorned the triumph of Octavianus at Rome. Cleopatra afterwards married Juba, king of Mauritania. [ANTONY, AUGUSTUS, CÆSAR.] (Plutarch's *Life of Antony*; Appian; Dion Cassius.)

CLE'PSYDRA (κλεψύδρα, from κλέπτειν, ὕδωρ). Before the invention of pendulum clocks, it was not unusual in astronomical observations to measure time by the flowing of water, upon a principle which, in its most simple application, resembled that of the hour-glass, but which was varied by contrivances for accuracy or ornament. Such an instrument was used, up to the time of Galileo, by Tycho Brahé for instance, but as he does not describe it among his instruments, we suppose he hardly considered it as among the primary aids of an observer.

The Chaldæans, it is said, divided the zodiac into twelve equal parts, as they supposed, by allowing water to run out of a small orifice during the whole revolution of a star, and dividing the fluid into twelve equal parts, the time answering to each part being taken for that of the passage of a sign over the horizon. The authority for this story is Sextus Empiricus (*Adv. Math.* cap. 21), who adds, that they regularly used the instrument in finding their astrological data, and remarks that the unequal flowing of the water, and the variations of temperature of the atmosphere, would affect the accuracy of their results. Pliny mentions Scipio Nasica as the first who introduced clepsydras into Rome.

We might perhaps object to Sextus Empiricus as an authority on Chaldee usages, but a good presumption of the early use of clepsydras in India is afforded by the arithmetical treatise of Bhascara, written in the twelfth century. The prediction at the birth of his daughter, Liliwati, was that she should die unmarried. The father determined to have at least one struggle against the prophecy, and accordingly procured a bridegroom and an astrological determination of a lucky hour. The girl remained in her ornaments near the clepsydra, watching for the moment when she and her parent might set fate at defiance. But at length it was ascertained that the hour was past; and on examining the clock, which should have prevented such a catastrophe, it was found that a pearl had escaped from the daughter's dress and closed the orifice through which the water should have flowed. The father, thus disappointed, said to his unfortunate daughter, 'I will write a book of your name, which shall remain to the latest times.' The Liliwati accordingly remains, and bids fair to realize the prediction. (Taylor's *Liliwati*, Bombay, 1816.)

In the account given by Vitruvius (*De Architectura*, lib. ix.), he attributes the invention to Ctesibius: but the instrument described is so complicated that we by no means suppose he intends to assert that this was the first application of the principle even at Alexandria. Some mode of measuring time by the efflux of water, however rude it might be, was used at Athens before the time of Ctesibius, as we see by various passages in Demosthenes. The instrument described by Vitruvius is an elaborate contrivance, which shows the hour, day, month, and sign of the sun. The astronomical clepsydra was rejected by Ptolemy on account of its imperfections, and it is not necessary to follow the moderns through the various modifications under which they have attempted to apply the principle. Such instruments continued to be common, as toys at least, till the middle of the last century.

If we suppose a clepsydra made of a glass cylinder, with a very small orifice at the bottom, and the apparatus to be filled with water, and the orifice then to be opened, the upper surface of the fluid will not descend equally in equal times, according to the notion which Sextus Empiricus attributes to the Chaldæans. If the water be perfectly pure, and the orifice very small and unclogged, the following will be the law of descent. Ascertain first the whole time of emptying the cylinder: then in the fraction m of the whole time, the fraction $m\,(2 - m)$ of the fluid will have discharged itself; or that same fraction of the whole height will have been fallen through. Thus in one-half the whole time of emptying, $\frac{1}{2}(2 - \frac{1}{2})$ or $\frac{3}{4}$ of the whole fluid will have been discharged, while in $\frac{1}{4}$ of the whole time $\frac{7}{16}$ of the whole will have been discharged. It is totally out of the question to suppose that the ecliptic was so nearly divided into twelve equal parts as actually was done, by any such imperfect process; though it is not impossible that by keeping the clepsydra constantly full, or very nearly so, equal times may have been estimated by the discharge of equal bulks of fluid. Supposing the cylinder to be kept constantly full, it would discharge its own bulk of fluid in exactly one-half the time in which it would empty itself undisturbed.

CLE'PTICUS, a genus of fishes, of the section Acanthopterygii and family Labridæ.

But one species of this genus is known (*Clepticus genizara*), and this is from the Antilles.

The generic characters are:—head obtuse; mouth protractile; teeth minute, barely perceptible to the touch; body elongate, lateral line uninterrupted; dorsal and anal fins covered with scales nearly to their outer margins.

CLERC, JEAN LE, born at Geneva in 1657, was the son of Etienne le Clerc, and nephew to David le Clerc, a clergyman and professor of Hebrew at Geneva, both known for several theological works. Jean le Clerc early manifested great capabilities for learning joined to an extraordinary memory. He travelled in France and England, and at last settled at Amsterdam, where he became professor of philosophy and belles lettres and of the ancient languages. He wrote a vast number of books, of very unequal merit, on all sorts of subjects. Those which made most noise at the time concern Biblical history and theological controversy, such as Latin commentaries on various books of the Bible, 5 vols. fol., Amsterdam, 1710-31; 'Harmonia Evangelica,' in Greek and Latin, fol., 1700; 'Traduction du Nouveau Testament, avec des notes,' 4to., 1703. These works pleased neither Catholic nor Protestant divines, from their having a tendency to Socinianism—a tendency made still more manifest by another work generally attributed to him, entitled 'Sentimens de quelques Théologiens de Hollande touchant l'Histoire Critique du Vieux Testament,' followed by a 'Défense' of the same work, 2 vols. 8vo., 1685. In these the author openly attacks the inspiration of the Scriptures and the very foundation of Revelation. As a critic, Le Clerc published his 'Ars Critica,' 3 vols. 8vo., 1712-30, a work which is much esteemed; and he also edited the 'Bibliothèque Historique et Universelle,' a periodical begun in 1687 and closed in 1693, making 26 vols. 12mo.; the 'Bibliothèque Choisie,' 1712-1718, 28 vols. 12mo.; and the 'Bibliothèque Ancienne et Moderne,' 1726-30, 29 vols. 12mo. These literary journals enjoyed a good reputation in their days. He also wrote—1. 'Parrhasiana, ou Pensées diverses sur des matières de Critique, d'Histoire, de Morale, et de Politique,' 2 vols. 12mo., 1701, a compilation to which he has added some hasty reflections, and many favourable comments upon his own works. 2. 'Histoire des Provinces Unies des Pays Bas,' from 1650 to 1728, 2 vols. fol., Amsterdam, 1738. 3. 'Histoire du Cardinal de Richelieu,' 2 vols. 12mo., 1714; 4. 'Traité de l'Incrédulité,' 8vo., 1733, in which he examines and discusses the various motives and reasons which occasion many to reject Christianity: this work is written with considerable talent and judgment. He also wrote a number of polemical works and pamphlets, most of which were tinged with bitterness and dogmatism. Le Clerc was one of the first critics of his age, but it was an age in which the critical art had not attained a high degree of excellence. He was learned, had quickness and penetration, and a great facility of composition; but he generally wrote in haste and upon too many and various subjects, having at times five or six works in hand at once. He published also a supplement to Moreri's Dictionary, and several editions of ancient classics, among others, Livy, Ausonius, Sulpicius Severus, &c. This edition of Menander and Philemon's fragments was severely criticised by Dr. Bentley. In 1728, while he was giving his lecture, Le Clerc suddenly lost the use of his speech through a paralytic stroke. His memory also failed him, and he lingered some years in a state bordering upon idiocy. He died at Amsterdam, on the 8th of January, 1736.

CLERGY, a collective term, under which that portion of the population of a country is comprehended who are in holy orders. It is used in contradistinction to *laity*, which comprehends all other persons. Like most ecclesiastical terms, it is of Greek origin, the word κληρικός (clēricus) having been used in the sense of 'appertaining to spiritual persons' by the Greek ecclesiastical writers. From *clericus* comes the word *clerk*, which is still a law-term used to designate clergymen, but which appears antiently not to have been confined to persons actually in holy orders, but to have been applied to persons possessed of a certain amount of learning.

The distinction of clergy and laity in the Christian church may be considered as coeval with the existence of the church itself; for in the apostolic period there were officers in the church specially appointed to discharge the duties of pastors or deacons, and even, as many suppose, bishops or overseers, who had the superintendence of various inferior officers. These persons, though they might not perhaps be entirely relieved from the ordinary duties of life so that they might devote themselves exclusively to their sacred office, yet must necessarily have been nearly so, and it is certain that they were nominated to their offices by some peculiar forms. Very early however the distinction became complete. The bishops, priests, and deacons of the Christian church, each ordained to the office in a manner which it was believed the founders of Christianity appointed, and each supposed to have received a peculiar spiritual grace by devolution from the apostles and from the sacred founder of Christianity himself, soon formed a distinct body of men demanding to be distinguished by some particular appellation.

In all Christian nations the distinction has been recognised by the political authorities, who have allowed certain social privileges or exemptions to the clergy. No inconsiderable share of temporal power, extending not only over the members of their own body, but over the laity, has in most states been conceded to them. In the great German confederation the sovereign power in some of the states was vested in ecclesiastics; while at Rome there has been for many ages an elective monarchy of ecclesiastics, in whom all temporal as well as spiritual authority has been vested.

It is easy to account for the ascendency of the clergy in the middle ages, and for the acquisition by them of so many valuable exemptions, and so much actual power. They were the best instructed part of the population. The learning of the age was almost exclusively theirs; and knowledge, if it is not itself power, is at least a means of obtaining it. Beside this they had a most powerful instrument with which to work upon the ruder minds of the laity, in the power vested in them of alone administering the sacraments of the church, and of regulating alone under what circumstances those sacraments ought to be administered. This enabled them to win acquiescence in any favourite design, sometimes by gentle influences and sometimes by terror.

The history of almost every country of modern Europe presents instances of struggles between the laity and the clergy for power or privilege. Our limits will not permit us to enter on these, not even on the struggles of this kind in our own country, where they were as determined, and sometimes as fierce, as in any country of Christendom. All power in the clergy of England to erect an authority dangerous to the laity, or to secure to themselves political immunities or privileges inconsistent with the general good, was broken at the Reformation. The clergy of England then became but a fragment of a once great and well disciplined body, dispersed through the whole of Christendom, which, when acting with common effort, and putting forth all its strength, it had been difficult for any single temporal prince to resist with effect.

We shall take from Blackstone a short statement of the privileges which the law of England allows to the clergy. They are but a faint shadow of the privileges which the clergy enjoyed before the Reformation. A clergyman cannot be compelled to serve on a jury, or to appear at a court leet or view of frankpledge. He cannot be compelled to serve the office of bailiff, reeve, constable, or the like. He is privileged from arrest in civil suits while engaged in divine service. He could claim benefit of clergy more than once. (BENEFIT OF CLERGY, p. 228.) Such are the legal exemptions. On the other hand, the clergy cannot now sit in the House of Commons, nor can they engage in any kind of trade, though sometimes clergymen have been brought within the scope of the bankrupt laws. By the law as it stood previously to the 57 Geo. III., c. 99, they were not allowed to take lands to farm, but by that act (s. 2) they are permitted (with the consent of the bishop of the diocese) to farm lands to the extent of 80 acres for a term not exceeding seven years.

The clergy meet by delegates in convocation at the beginning of every new parliament, but this is now merely a form, the king, as supreme head of the Church of England, invariably dissolving the convocation before they can proceed to any business. They have however still courts in which jurisdiction is exercised touching ecclesiastical affairs, and causes testamentary or matrimonial, and where the church's censures are directed against particular classes of offenders. To them also belongs the whole ecclesiastical revenue, with divers fees or customary payments, and to them also the whole regulation of the terms of admission to their order.

The three great classes of the English clergy are the bishops, priests, and deacons. To be admitted into each of those classes requires a peculiar ordination. This distinction is of an entirely different kind from that which arises out of office or appointment. Of this kind of distinction there is in the English clergy the archbishop, the bishop, the dean and canons of a conventual or collegiate church (some of the canons being in many instances invested with particular characters, as precentors, succentors, and the like), the archdeacon, the rural dean, the dean of some church whose constitution is peculiar, the rector, the vicar, the curate in some chapels called parochial, the minister in some newly-founded chapel, whether a chapel of ease or what is called a proprietary chapel, assistant ministers to aid the vicar or the rector in some churches of antient foundation, and, finally, a body of persons called curates, who are engaged by the incumbents of benefices to assist them in the performance of their duties, but who are not dismissible at the caprice of the incumbent, nor left by law without a claim upon a certain portion of the profits of the benefice.

These are the various offices in which the clergy of the church of England are distributed. As the subject is of importance, and seems to be but imperfectly understood, we shall here briefly notice wherein lies the distinction of *rector*, *vicar*, and *curate*, to one of which belongs nearly every individual of the English clergy.

For this purpose, England must be regarded as divided into something more than 10,000 small districts, varying in extent, called parishes. Each of these parishes must be regarded as having its church, and one person (or in some instances more than one), who ministers divine ordinances in that church. This person, whose proper designation is *persona ecclesiæ*, enjoys of common right the tithe of the parish, and has usually a house and glebe belonging to his benefice. When this, the original arrangement, is undisturbed, we have a parish and its *rector*. But in the times before the Reformation it was a very common practice of the *patrons*, or persons who had the right to nominate the persona or rector, to give that right to some monastery or community of religious. Such community, instead of nominating some person as rector, would profess to discharge the duties of the parish by sending from time to time one of its own body to perform those duties, or by engaging some person at a stipend, settled by themselves, to perform the duties, they taking the tithe and other profits of the benefice to the use of their house. Some few of the antient parishes of England have thus been entirely stripped of their tithe and the other property out of which a resident minister might have been supported; but in nearly every instance the bishops interfered, and compelled the religious houses to settle some determinate share of the profits of those benefices upon a clergyman who should be fixed in the parish upon the nomination of the monastery, but no more removable than if he had really been the persona or rector. This person was called the *vicar*, *vicarius*, that is, one who stands in the place of another; and the other whom the vicar represented was in this instance the religious community, in whom vested the two characters of patron and rector. The provision made for the support of the vicar varied in different parishes, but it was usually some fixed portion of the tithe with the oblations. The agreement however, which was between the religious community and the bishop, was arbitrary, and hence it is that we find the vicars so variously endowed. At the Reformation, whatever interest the religious communities possessed in the parishes was seized by the crown, and has since been either retained by it, or, what has usually been the case, has been sold to private persons, whence arises the class of the *lay impropriators*, who are, in fact, the rectors of the parish, the performance of the spiritual duties devolving on the vicar. *Curates* who are not merely assistants to a rector or a vicar, are in general incumbents of churches in which no vicarage was ever ordained, or incumbents of chapels of foundation later than the æra of the foundation of parishes, and endowed by the special bounty of particular persons. [CHAPEL.]

CLERGY, BENEFIT OF. [BENEFIT OF CLERGY.]

CLE'RIDÆ (*Tillidæ*, Leach), a family of Coleopterous insects, of the section Malacodermi. Characters: palpi generally clavate; mandibles dentated internally; penultimate joint of the tarsi bilobate; antennæ more or less serrated or terminated by a club; body generally cylindrical and pubescent; head and thorax narrower than the abdomen; eyes emarginated. Most of these insects are found on flowers and some on old trees: the larvæ of those which are known are carnivorous.

The principal genera included in this family are *Cylindrus*, *Tillus*, *Priocera*, *Axina*, *Eurypus*, *Thanasimus*, *Opilus*, *Clerus*, *Necrobia*, and *Enoplium*.

The genus *Clerus* is thus characterized: maxillary palpi with the terminal joint thicker than the rest, compressed, broadest at the apex, and truncated; labial palpi with the terminal joint securiform; antennæ with the basal joint rather long, the seven following short, the three terminal joints forming a compressed knob of the form of a reversed triangle; tarsi exhibiting only four distinct joints.

Two species of this beautiful genus (*Clerus apiarius* and *C. alvearius*) are natives of this country, but they are here of rare occurrence, though in Germany, France, and Italy, they are common, and are found on the flowers of umbelliferous plants.

Clerus apiarius varies from half to two-thirds of an inch in length, and is very thickly covered with hairs; it is blue, the elytra are red, and have three blue fasciæ, one of which is at the apex.

The larva of this species feeds upon those of the common hive-bee, and is sometimes very destructive to hives.

Clerus alvearius very much resembles the species just described, differing chiefly in having a blue spot in the region of the scutellum in addition to the three blue fasciæ on the elytra; its larvæ feed upon those of the mason bees.

Dejean enumerates thirty-seven species of the genus Clerus in his 'Catalogue des Coléoptères,' and it appears that the genus is not confined to any particular part of the globe, as is frequently the case.

CLERK, JOHN (of Eldin, N.B.), was the inventor of one of the most important parts of the modern British system of naval tactics. In 1779 he communicated to some friends his notions concerning what is technically called 'breaking the line.' In 1780 he communicated his plan to Mr. Richard Atkinson, the particular friend of Sir George (afterwards Lord) Rodney, and that distinguished officer, before leaving London, said he would strictly adhere to it in fighting the enemy. On the 12th of April, 1782, when the experiment was tried for the first time, it led to Rodney's decisive victory over the French, under De Grasse, in the West Indies. From that time the principle has been adopted by all British admirals; and during the last war, when Howe, Nelson, and others, executed the manœuvre in perfection, it was universally attended with success. (See *An Essay on Naval Tactics, systematical and historical*, with explanatory plates, in 4 parts, by John Clerk, Esq., of Eldin, Fellow of the Society of Scottish Antiquaries, &c.; also an excellent article in the *Edinburgh Review*, vol. vi., p. 301.) A few copies of the first part of this valuable Essay were distributed among friends in the beginning of 1782. This part was reprinted and published in 1790, and the second, third, and fourth parts were added in 1797. Mr. Clerk was no sailor, and had never even made a single sea-voyage.

Such is the account given by Mr. Clerk's relatives and friends, but it has been indignantly contradicted in various publications by General Sir Howard Douglas. In a circumstantial narrative of Admiral Rodney's battle, he proves that the passage of the British through the enemy's line, and thereby cutting off the rear ships, arose from the chance position of the two fleets, and was one of those happy and unpremeditated decisions of the moment which always characterize a great and successful commander. By a close examination of dates, he also shows that Mr. Clerk's ingenious essay could not have been communicated to Lord

Rodney before the engagement took place; and he supports these statements by letters and other documents which have fallen into his hands since the death of his father, the late Admiral Sir Charles Douglas, who was at that time Rodney's 'Captain of the Fleet,' and therefore minutely acquainted with all the transactions. (See the several publications on this subject by Lieutenant-General Sir Howard Douglas, Bart.)

CLERMONT, the name of several towns in France, of which the following are the only ones of importance.

CLERMONT-FERRAND is the capital of the department of Puy de Dôme; it is in the neighbourhood of the Puy de Dôme, and on a torrent which, rising on the side of that mountain, flows into the Allier: about 216 miles S. by E. of Paris, in a direct line, or 232 miles by the road through Nevers and Moulins: in 45° 46′ N. lat., and 3° 5′ E. long.

It is not known whether this town existed when Julius Cæsar invaded Gaul: it was certainly not the Gergovia, in attacking which he experienced his most considerable check. Strabo mentions it under the name of Νεμωσσὸς (Nemossòs), and calls it the metropolis of the Arverni, from whom Auvergne is named: Ptolemy calls it Αυγουστονέμετον. In the Theodosian table the name is found in a contracted form, Aug. Nemeto. At a subsequent period it assumed the name of the tribe to which it belonged; and it appears under the name of Arverni, or Urbs Arverna, in the pages of Ammianus Marcellinus and Sidonius Apollinaris, in the 'Notitia Imperii' and the 'Notitia Provinciarum Galliæ.' In the middle ages, the castle by which the town was defended, was named *Clarus Mons;* and this name, which at first was restricted to the castle, was afterwards extended to the whole town.

In a council at Clermont, held A.D. 1095, the first crusade was resolved on. Pope Urban II. presided. The transactions of this council were numerous and important. In the middle ages, and up to the period of the French revolution, Clermont ranked as the capital of Auvergne. The bishopric originated in the third century, and the bishop held the first rank among the suffragans of the archbishop of Bourges; and until the erection of the bishopric of St. Flour in 1317 was the only bishop in Auvergne. The diocese at present comprehends the department of Puy de Dôme, which had in 1832 a population of 573,106.

This town is delightfully situated in a part of the rich plain of the Limagne, in a nook nearly embosomed in the hills which rise round the base of the Puy de Dôme, and which surround the town on every side except the E. and N.E.: it is close to a small mountain-torrent which flows into the Allier, from which river Clermont is distant about six or seven miles. In approaching the town from Paris, the traveller passes through the little town of Montferrand, containing some 3000 or 4000 inhabitants, situated on a little eminence, and having very steep streets. It was one of the strongest places in Auvergne; but its walls have been demolished and the ditches filled up. This place has been, since 1731, regarded only as a suburb of Clermont. It has some cavalry barracks, the diocesan seminary for the priesthood, and a church remarkable for its large nave unsupported by pillars. Here also is held a large cattle-market. From Montferrand to Clermont is a noble road or avenue, two miles long, perfectly straight, and bordered with willows and walnut-trees. Clermont itself, built on an eminence, forms, when viewed at a little distance, a noble termination to this avenue, and inspires the traveller with a notion of its beauty which the interior of the town does not keep up. It is not well laid out; the streets are narrow, and the houses, though not ill built, yet present, from the dark colour of the lava, which is the chief building material, a sombre appearance; several are however white-washed. There are several *places*, or squares; and the original town of Clermont is separated from the faubourgs, which (exclusive of Montferrand) comprehend half its extent and a third of its population, by a line of boulevards, which are for the most part planted with trees. The *place* of Le Taureau is remarkable for a handsome fountain in form of an obelisk, dedicated by the townsmen to the memory of General Desaix, who was born in the neighbourhood: this *place*, and those of Poterne and of L'Espagne, command most agreeable prospects: that of Champleix is adorned with a Gothic fountain, richly sculptured, which was formerly in the cathedral close.

Of the public buildings the cathedral is the principal: it is on the central point of the city; and though it has never been completely finished, it is regarded as one of the finest monuments of Gothic architecture in France. It is built of the lava of Volvic, the dark hue of which is in keeping with the style of the building. Of five towers which formerly adorned it, four were destroyed in the revolution; from the summit of the remaining one is a beautiful prospect, extending on every side of the town. The nave and choir are remarkable for their lofty elevation, and the lightness and arrangement of the pillars which support their vaulted roofs. The carving of the wood-work of the choir is exquisite. There are some beautiful painted windows, but they have been much damaged. This cathedral, the fourth which has been built here, was begun as far back as A.D. 1248. The first cathedral was destroyed by the Allemanni, the second by Pepin le Bref, and the third by the Northmen. The church of Notre Dame du Port is very ancient; several parts of the present building belonged to the original church, erected in the sixth century, and destroyed by the Northmen in the ninth.

There are two handsome halls, or covered markets, one for linens, the other for corn; a town-hall with courts of justice, lately built; and a handsome *collège royal*, or high school, which contains 500 pupils. There were, before the revolution, several monastic establishments, the buildings of some of which yet remain, and are of good appearance; there are some good inns, and a number of handsome private houses. The *place* Jaude, used as the *place d'armes*, or parade for the troops, is a very large parallelogram surrounded by private houses mostly new and well built.

The inhabitants of Clermont amounted, in 1832, to 24,077 for the town, or 28,257 for the whole commune: we presume that in the latter number the population of Montferrand is included. Clermont is not the seat of any important manufacture, but considerable trade is carried on; the situation of the town causing the inhabitants of the department of Puy de Dôme, and of the neighbouring departments of Cantal, Lozère, Haute Loire, and Aveyron, to resort to it to exchange their cheese, their cattle, and their wool, for the articles which are sent from Paris. Hemp, linens, fruit, and the wines of the Limagne, find a market here: the wines were commonly sent to Paris, until the charges made at the barriers of the metropolis on the inferior wines were rendered equal to those on the wines of superior quality. Some coarse woollen cloths, paper, hats, silk stockings, pipe-clay, sweetmeats, pottery, Prussian-blue, and glue, are made in the town; there are some tan yards and breweries, and a refining house for saltpetre. Clermont is one of the places by which the commercial communication between Lyon and Bordeaux is carried on. The transit of goods is chiefly effected by mules; there is no navigable river in the neighbourhood; the navigation of the Allier does not commence till many miles lower down. Clermont is famous for its preserves of apricots and apples.

There is a high school (already mentioned); a public library of 16,000 volumes, tolerably well chosen, which owes its origin to the celebrated Massillon, once bishop of Clermont; a museum of mineralogy, very rich especially in the minerals of the district; a large botanic garden, well kept up; and courses of public instruction, delivered gratuitously on botany, mineralogy, geology, arithmetic, and geometry, applied to the arts; writing, drawing, music and architecture. The library of the Academy of Sciences, Arts, and Belles Lettres of the town is adorned with a bust of Delille and a statue of Pascal. There is a handsome theatre near the cathedral. There are several hospitals: the Hôtel Dieu and the Hôpital Général are the principal. The Cour Royale, to the jurisdiction of which the department is subject, has its seat not at Clermont, but at Riom, a small town in the department. Clermont is the seat of a conseil académique.

Among the eminent natives of Clermont, Pascal, the author of the 'Lettres Provinciales,' holds the first place.

Clermont is distinguished by some remarkable mineral springs: that of Jaude, near the *place Jaude*, is intermittent: it flows steadily for a few minutes, then suddenly gushes out with a violent ebullition, which also lasts some minutes; it then returns to its previous equable flow, and then alternates. The fountain of St. Alyre, which derives its name from the Benedictine abbey of St. Alyre, in the Faubourg St. Alyre, is still more remarkable. It forms a streamlet which, running through some kitchen gardens, deposits as it runs a calcareous sediment, and gradually raises its bed until it attains the level of its source, when the waters, unless a new channel be found for them, overflow on all sides. These deposits harden as they are formed, and the proprietors of the gardens are obliged, from time to time, to alter the course of the stream and to break up the incrustations to prevent the land being covered by them. In one instance where they allowed the incrustation to remain and increase, the consequence has been the formation of a natural dyke or wall 250 or 260 feet long, which preserves nearly the same level, while the ground on which it stands has a gradual slope, so that it appears at one end to rise out of the ground, while at the other it has a height of 17 feet and a breadth of 13 feet. At its extremity this dyke has formed a natural bridge over a brook which crosses its direction, and into which the streamlet flowed. The raising of the bed of the streamlet led to the formation of a small cascade, which increased in height as the bed rose higher and higher, and threw its waters farther into the current of the brook: this current prevented the extension of the dyke at the bottom, but the continued deposits at the top caused it to impend more and more over the stream, and to throw out its waters farther until they fell on the opposite bank, and there forming new concretions, completed the arch. This bridge is somewhat broken. The owners of the gardens turn the streamlet to a profitable account by placing, where the waters have a fall, various objects, as fruits, flowers, birds, and other things, which are speedily covered with a hard calcareous crust.

The plateau of Gergovia, some five or six miles to the south-east of the town, is said by Vaysse de Villiers to have only the name in common with the Gergovia of which Cæsar had to raise the siege in his campaign against Vercingetorix (*Comment. de Bell. Gall.*, lib. vii.); but D'Anville seems to incline to a contrary opinion. The arrondissement of Clermont contained, in 1832, a population of 171,566. (Malte Brun; Vaysse de Villiers; Balbi; Expilly; Puchet, *Diction. de Géographie Commerçante; Tour in France* by F. J. Carey.)

CLERMONT DE LODÈVE, a town in France, in the department of Herault, near the right bank of the little river Lergue, which flows into the Herault. It is 367 miles S. by E. from Paris in a straight line, in 43° 38′ N. lat. and 3° 26′ E. long.

Clermont de Lodève is situated on the slope of a hill, in a territory fertile in grain and fruit, and supplying abundant pasturage: there is an antient castle. The population, in 1832, amounted to 5905 for the town, or 6199 for the whole commune. The inhabitants are engaged in the manufacture of woollen cloth for the Levant trade (a branch of industry introduced in 1678) and for home consumption, handkerchiefs, worsted and cotton stockings, verdigris, cream of tartar, vitriol, cotton yarn, and leather. In these articles, as well as in the agricultural produce of the neighbourhood, sheep, wool, wine, brandy, oil, and almonds, considerable trade is carried on. Clermont furnishes wool for the manufactures of Carcassonne, Lodève, Aubenas, Bedarrieux, &c. There are several considerable markets in the week.

CLERMONT-OISE. [OISE, DEPARTMENT OF.]

CLEVES (Kleve, German), the most north-westerly district of the kingdom of Prussia, and part of the old duchies of Cleves and Guelderland, is at present one of the thirteen circles of the province of Düsseldorf, in the Prusso-Rhenish provinces. It contains about 185 square miles; six towns and seven villages; and in 1831 had a population of 42,194 souls, of whom about 37,500 are Roman Catholics. These numbers give an increase of 3582 since the year 1817. Cleves is bounded on the west by the Rhine, and on the north and west by Holland; the surface is a complete level, and the soil, though very sandy in many parts, has in general been rendered extremely productive by careful cultivation. In the westerly districts lies the extensive Reichswald, or Forest of Cleves: 31,000 acres of this circle are occupied by woods and forests, while of the remainder 58,350 acres are arable land, and 23,200 are in meadows or pastures. The stock of horses, in 1831, was 3964; horned cattle, 16,893; sheep and goats, 7060. The produce is chiefly wheat, rye, barley, oats, buckwheat, peas and beans, potatoes, cloverseed, butter, and cheese, of which three last-mentioned articles much is exported. Cleves is divided into eleven districts (Bürgermeistereien), and contains, besides the capital, the towns of St. Oranenburg, between the Maass and Waall, 1100 inhabitants; Calcar, 1900; Goch, a manufacturing town on the Nies, 3350; Grieth, 1000; Griethausen, 700; and Uedem, 1300. On a heath near Goch is a village of 2700 inhabitants, called the Pfulzdorf, or palatinate village, from its having been built by emigrants from the Palatinate. The manufactures carried on in this circle are cotton-yarn, woollens, silks, cottons, linens, cutlery, leathers, &c.

Kellen, in the territory of Cleves, is conjectured to be the site of the Castra Ulpia Leg. xxx. (Amm. Marc. xviii. 2), and Goch, the Quadriburgum Gugerni, who were forced to abandon the country about Cleves and between the Maas, Waal, and Rhine, in the times of Tiberius. (Tacitus, *Annal.* iv. 26; Eutrop. vii. 9.)

CLEVES, the capital of the Circle, and formerly of the duchy of this name, is pleasantly situated on the Kermisdahl, about a mile from the banks of the Rhine, with which it communicates by the Spoy canal. It is walled, well built, and divided into the Upper and Lower towns; but the Upper being built on three hills, the streets are steep and irregular. Formerly it was fortified, and was considered a place of strength until the middle of the sixteenth century. It contains a cathedral, built in 1346, with two towers, a Catholic church, three Protestant churches, a synagogue, and a royal palace, called the Schwanenburg, the tower of which, built by the duke of Cleves in 1439, is extremely massive, and being on the highest point of the hill on which the palace stands, forms a stately ornament to the town. There are extensive gardens round the palace, which contains a valuable collection of Roman antiquities found in the town and its environs: it is now used partly as government offices, and partly for a prison. Cleves possesses a high-school, three hospitals, a house of industry, house of correction, &c. The houses, about 950 in number, are built in the Dutch style; the population is about 7000; it increased, between 1765 and 1810, from 4977 to 5200; and between 1817 and 1831, from 6511 to 6967. The manufactures consist of yarns, cotton goods, silks, woollens, flannels, stockings, linens, tobacco, brass-ware, &c. There are three squares, or open spaces, and in the vicinity a park of about 700 acres, and a chalybeate spring surrounded by handsome grounds, which was opened in 1742. The place is much frequented by visiters in summer. Over the Middle Gate is a statue of Eumenius Rhetor, a Roman, who founded the first schools in Cleves. 51° 47′ N. lat., and 23° 46′ E. long.

CLIENT (Cliens), apparently derived from the verb *cluo*, 'to listen to,' 'to obey.' From the origin of the institutions of antient Rome, there appears to have existed the relation of patronage (patronatus) and clientship (clientela) Romulus, the founder of Rome, was, according to tradition, the founder of this institution. The cliens may perhaps be compared with the vassal of the middle ages. Being a man generally without possessions of his own, the client in such case received from some patrician a part of his domains as a precarious and revocable possession. The client was under the protection of the patrician of whom he held his lands who in respect of such a relation was named patron (patronus), *i. e.*, father of the family, as matrona was the mother, 'in relation to their children and domestics, and to their dependents, their clients.' (Niebuhr.) It was formerly the opinion that every plebeian was also a client to some patrician; but Niebuhr, in speaking with reference to the proposition that 'the patrons and clients made up the whole Roman people,' affirms that the proposition is only true 'if applied to the period before the commonalty was formed, when all the Romans were comprised in the original tribes by means of the houses they belonged to.' In the later times of the republic the clients probably, for the most part, consisted of liberti and their descendants. Between the patron and his client there existed mutual rights and obligations. The patron was bound to take his client under his paternal protection; to help him in case of want and difficulty, and even to assist him with his property; to plead for him and defend him in suits. The client on his part was bound in obedience to his patron, as a child to his parent; to promote his honour, assist him in all affairs; to give his vote for him when he sought any office, to ransom him when he was made prisoner and not able to pay the ransom himself; and to contribute to the portion of the patron's daughter. The patron succeeded to his property when the client died without heirs; which was also the law of the twelve tables in the case of a freedman

(Ulpian., *De Bonis Libertorum*) who died intestate and left no heir (*suus heres*). Patron and client were not permitted to sue at law, or give evidence against one another.

Originally patricians only could be patrons; but when, in the later times of the republic, the plebeians had access to all the honours of the state, clients also were attached to them.

The terms patronus and libertus, or even patronus and cliens, as used in the later years of the republic, and under the emperors, cannot be considered as expressing the same relation as the terms patronus and cliens in the early ages of Rome, though this latter relation was probably derived from the earlier one. When a foreigner who came to reside at Rome selected a patron, which, if not the universal, was the common practice, he did no more than what every foreigner who settles in a strange country often finds it his interest to do. The existing relationship at Rome between patron and client facilitated the formation of similar relations between foreigners and Roman citizens; the foreigner thus obtained a protector and perhaps a friend, and the Roman increased his influence by becoming the patron of men of letters and of genius. (See Cicero *pro Archia*, c. 3, and *De Oratore*, i. 39, on the 'Jus Applicationis.' See also Niebuhr, vol. i., p. 316, &c., and the references in the notes.)

As a Roman client was defended in law-suits by his patron, the word client is used in modern times for a party who is represented by a hired counsellor or solicitor.

CLIFTON. [Bristol.]

CLIMATE is a word which has been transplanted from the Greek into every modern European language. The Greek word *κλῖμα* (from *κλίνω*, to incline) seems originally to have been used to express the apparent inclination of the heavens towards the horizon; and it was afterwards used as a technical term in astronomy and geography to indicate generally the distance on the celestial sphere, as well as on the terrestrial globe, from the equinoctial line towards the poles.

The plural of this word, *κλίματα* (climata), however, was used in a somewhat different sense, and answered, in some degree, to our parallels of latitude. The Greeks supposed the celestial sphere to be divided into girdles or zones, parallel to the equator, and surrounding the whole sphere. They then endeavoured to ascertain through what stars the parallel circles forming the boundary-lines of such a zone were to be drawn, and what stars fell within the zone. The same division they afterwards applied to the terrestrial globe, ascertaining first the places through which the boundary-lines of the zones ran, and then determining at what distance from them the intermediate places were situated. These zones were called climata, or climates, and were used by them as we now use the degrees of latitude.

These climata of the Greek geographers however did not always embrace an equal number of degrees of latitude. The principle of the division into zones was the length of the longest days; and a difference of half an hour generally determined the breadth of one of these climates. For instance, one of the boundary-lines of a zone would run through the places in which the longest day had thirteen hours, and the other through those in which it was thirteen hours and a half. This was sufficient for their purposes in those parts of the globe where there was only a small number of places the position of which had been determined. But it was not sufficient for those parts where the number of places determined was greater, as in Greece and the adjacent countries. Here they gave a less width to the climata, allowing only a quarter of an hour for the difference between the boundary-lines of a climate. For instance, the southern boundary-line of such a zone would run through the places whose longest day was fourteen hours, and the northern through those in which it was fourteen hours and a quarter.

The greater exactness of modern astronomical observations has rendered this division of the globe useless, and we have substituted for it the notation by degrees of latitude. The Greeks, of course, made use of these climata as we do the degrees of latitude, to indicate in a general way the comparative temperature which a country enjoys by reason of its smaller or greater distance from the equator. Modern nations have adopted the term climate, but with a somewhat enlarged signification. Climate, with us, not only implies the greater or less degree of heat which a country is subject to, but also the quantity of moisture in its atmosphere, and, in general, all the phenomena which affect vegetation, and render a country a fit abode for men and animals.

Heat and moisture, properly speaking, constitute climate. The other phenomena, such as winds, electricity, &c., affect these constituents of climate; but they require a separate consideration, as modifiers of climate, according to the view which we take of the subject.

We may observe, that those places where a high temperature is combined with a great quantity of moisture, are the most fertile, and display the most luxuriant vegetation, provided the surface is not formed of naked rocks; but even the solid rocks will in time yield to the combined influence of heat and moisture, and be clothed with a rich vegetation.

The latitude of a place is generally considered as the principal circumstance in determining its temperature. It is laid down as a fact, that countries lying under the equinoctial line or close to it are subject to the greatest comparative heat, which constantly decreases with the increase of distance from that line. This general rule must be admitted to be true for all the countries which lie between the tropics and the pole; but it may be questioned how far it is true of the countries within the tropics. A glance at a globe or sphere shows that the sun at the end of the first month after the equinox has already advanced 12° of latitude towards the tropic; but in the second month it traverses only 8°. At the end of the second month it is consequently 20° from the equator. There remain therefore only 3½° to be traversed in the third month. The sun recedes from the tropic in the same way. It passes the first month through 3½°; the second through 8°; and the third through 12° of latitude. Hence it is evident, that at all places between 20° and 23½° of latitude, the solar rays during two months fall at noon either perpendicularly, or at an angle which deviates from a right angle only by 3½° at most. If we take a place intermediate between 20° and 23½° of latitude, the solar rays must fall on it during two whole months, either perpendicularly, or in a direction still less removed from the perpendicular than in the former case. On the other hand, when the sun passes the equator, two places on which the vertical rays of the sun fall on two consecutive days are nearly ½° of latitude distant from one another; and a place situated exactly under the equator has only during six days the sun as near its zenith as the above-mentioned places near the tropics have it during two whole months. We might therefore presume, that the summer heat of the latter position must be much greater than that of places near the equator. This degree of temperature must be increased by the greater length of the longest days, which near the tropic are 13½ hours; but at the equator are always of the length of 12 hours.

This reasoning is not contradicted by experience. The countries in which the greatest degree of heat is experienced lie near the tropic of Cancer. They are the countries on the banks of the Senegal, the Tehama of Arabia, and Mekran in Beloochistan. The antients were not unacquainted with this fact; and one of their most ingenious inquirers, Posidonius, was so struck by the peculiarities of the countries near the tropic, that, for the purposes of physical geography, he wished to consider them as forming a particular zone, different both from the equatorial zone and from the temperate zone, and separating these two in the form of a narrow belt. He observes that these countries are characterized by the aridity and sterility of their soil, and that no rain falls there, while the regions nearer the equator, having abundance of rain and moisture, are exceedingly fertile. (Strabo, ii.)

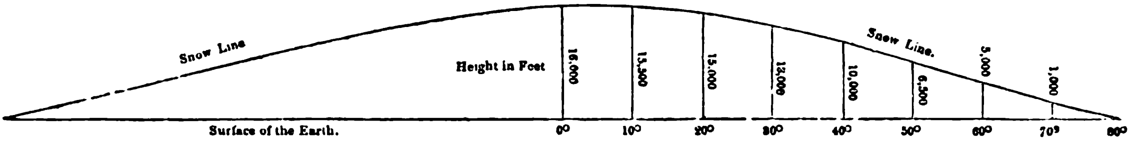
It remains however a question whether the mean temperature of places near the tropic is greater or less than that of places near the equator. During nearly eight months of the year the solar rays fall on the equator less obliquely than on the countries near the tropics; but it is not yet determined by exact observations if the greater degree of heat which these countries are subject to during that period is sufficient to compensate for the much greater degree of heat during the remainder of the year near the tropics. Very few meteorological observations made between the tropics have yet been published; and of these few we know not how they were made, and how they were affected by local circumstances. There is however a well-established fact which clearly seems to indicate that in summer the mean temperature near the tropics is higher than near the equator this is the line of perpetual snow, which in the Bolivian

Andes is found to be at least 1000 feet higher than in the Andes of Ecuador, which are situated under the equator.

Though the mean temperature differs greatly in countries lying in different degrees of latitude, the most intense degree of heat which is experienced in all countries between the equator and 60° of latitude is nearly equal. The thermometer rises almost every year at St. Petersburg above 90°; and it is observed that even on the coast of Guinea, and on the banks of the Senegal, it rarely exceeds 95°. There are certainly instances in which it has attained a much higher degree. Dr. Coulter observed it at 140° on the banks of the Rio Colorado (32° 30′ N. lat.); but such exceptions must be ascribed to local circumstances, especially to the reflection of the solar rays from an arid and sandy surface.

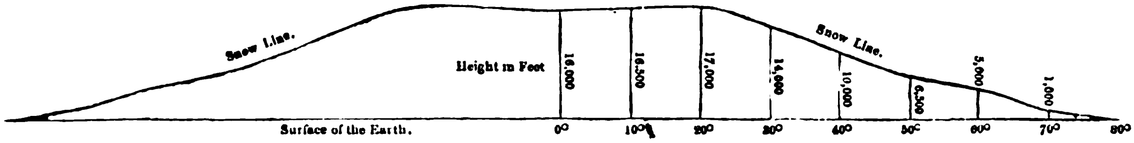
The general rule derived from geographical position, as to the distribution of heat over the surface of the earth, is subject to many exceptions, arising from local circumstances. But none of these local circumstances probably affect it so much as the elevation of the surface. It is a well-known fact, that near the tropics and the equator there are mountains which, owing to their great elevation, are covered with snow all the year round. The heat experienced in a given place not only depends on the greater or less obliquity of the rays of the sun, but also on the greater or less column of the atmosphere. The column of air is greatest on the surface of the sea and in such countries as are nearly on a level with it. The higher we rise above this level the more the air is rarefied, and the degree of heat due to the solar rays decreases. Thus we at last arrive at an elevation where the heat, even under the equator, is insufficient to melt the snow. As the density of the air and the intensity of the heat continually decrease as we rise higher, some attempts have been made to determine the law of the decreasing temperature. Alexander von Humboldt, who has made a great number of observations on the steep declivities of the Andes near the equator, came to the conclusion that the thermometer of Fahrenheit descends one degree when we rise 343 feet above the level of the sea, and one degree for every 343 feet more. Thus the thermometer may be used to determine in a rough way the heights of mountains or of elevated plains. The calculations of Humboldt however are only founded on observations made in the intertropical countries, and it is supposed that the same law will not be applicable in all its extent to places situated without the tropics.

As already observed, at a certain height above the surface of the sea, the heat caused by the solar rays is too feeble to melt the snow and ice: this limit has been called the snow-line, or line of perpetual snow, or line of perpetual congelation. This snow-line does not occur in all places at the same elevation, but is dependent on the mean temperature in summer, and consequently on the latitude of a place. In warm countries it is consequently found at a much higher elevation than in cold countries. It has been ascertained by numerous observations, that in the Andes of South America, near the equator, the summit of a mountain rising to less than 16,000 feet does not attain the snow-line; but in Norway, in 60° of lat., mountains with an elevation of 5000 feet are always covered with snow, and in the southern hemisphere the line of perpetual snow in the Straits of Magalhaens (52° S. lat.) is, according to Captain King, about 3500 or 4000 feet above the sea. At about 80° of N. lat. the snow-line is considered to come down to the surface of the earth. Numerous observations made on the mountains of Europe, combined with those made by Humboldt in South America, suggested the idea that the snow-line forms a regular curve (north and south) on the surface of the earth in the following way:



But more recent observation has shown, that we are still very imperfectly acquainted with the laws by which this important boundary-line in the atmosphere is determined. Mr. Pentland ascertained by a great number of observations, that in the Andes of South America, between 14° and 17° S. lat., the snow-line does not occur on mountains below the height of 17,000 feet. Poeppig, in traversing the Andes, near 11° S. lat., found that here also they were free from snow at an elevation several hundred feet higher than the snow-line under the equator. As the Bolivian and Peruvian Andes, on which these observations were made, exactly resemble those of Ecuador in their local circumstances, it may perhaps be a reasonable conjecture that the mean temperature in summer near the tropics is greater than under the equator; which is by no means improbable from other considerations, as we have shown above. The snow-line would then be represented, not by a curve of continuous curvature, but by one of this form.

Snow Line.



These observations on the elevation of the snow-line above the level of the sea, are however only applicable to mountains which rise with a steep ascent, and are not contiguous to table-lands. High table-lands have a higher temperature than isolated mountains of the same height. Humboldt observed that the elevated plains on which the towns of Bogotà, Popayan, Quito, and Mexico are built, have a much warmer climate than they would have if elevation above the sea were the only element that determined the temperature when the latitude is given. In comparing the mean temperature of these plains with that of the adjacent coast, he found that the thermometer, instead of descending one degree for every 343 feet, had only sunk so much for every 400 feet of perpendicular elevation. He thinks that this difference may be accounted for by supposing that the temperature of the atmosphere, under these circumstances, is considerably raised by the reflection of the solar rays from a plain of considerable extent. This supposition is confirmed by the circumstance of the different heights at which the snow-line occurs on the southern and northern declivities of the Himalaya mountains. On the southern declivity of that range, which rises rapidly from the low plains of the Ganges, Mr. Webb found the snow-line at an elevation of about 13,000 feet, corresponding pretty well with its latitude (about 30°); but on the northern declivity, which is about a degree farther north the snow-line ascends to 16,000 feet; an elevation which corresponds to that found under the equator. On this side however, the range, though very steep, does not descend to a low country, but terminates in an immense plain, the surface of which is about 10,000 feet above the level of the sea. There seems hardly to be a doubt that the great difference between the elevation at which the snow-line occurs on the two declivities is principally to be explained by the difference in the height of the plains which are respectively contiguous to them.

Though this subject has lately attracted much attention, we are far from being able to explain all the deviations from the rule which have been observed. Thus the Pyrenees and Mount Caucasus are under the same parallel. The snow-line on Mont Perdu, in the Pyrenees, was found by Raymond at the elevation of 8700 feet; but on Mount Elburz, in the Caucasus, it only occurred at the height of 10,880 feet, according to Englehardt and Parrot. This fact is the more remarkable, as the countries contiguous to the Pyrenees have a much warmer climate than those which enclose the Caucasus. It is conjectured that this difference may probably be explained by the difference in the respective hygrometrical states of the atmosphere; on which however the necessary observations are wanting, especially for Mount Caucasus.

From these considerations it is evident that the temperature of a country, so far as it depends on latitude and on the elevation of its surface above the level of the sea, may be determined with a certain degree of exactness, or at least within certain limits. But temperature is still affected by several other circumstances and phenomena, whose influence cannot be subjected to calculation, and consequently cannot be brought under positive rules; at least not in the present state of our knowledge. Such circumstances and phenomena are, the nature of the soil, the prevailing winds, the quantity of moisture, the electrical state of the atmosphere, and the physical character of the adjacent countries and seas.

With regard to the soil, it is a well-known fact that the temperature of countries whose surface is covered with sand is higher than that of those in which it consists of clay or other compact soils. It is likewise observed, that where the soil has been to a great extent cleared and brought into cultivation, the air is much drier and warmer in summer than in those tracts which for want of cultivation remain covered with swamps and marshy grounds. This, according to Darby, is the case in the cultivated parts of the United States, in which he asserts, contrary to the vulgar notion, that in the cleared and cultivated tracts the summer temperature has been raised, and that of winter diminished. The latter circumstance would seem a natural consequence of clearing the surface and exposing it during the winter months to the full influence of the north-west winds. In fact, as the country becomes more open, the range of the thermometer increases. As far as we know, no attempts have been made to ascertain to what amount such differences in the soil affect the temperature of a country, though our knowledge seems to be quite sufficient to assign the reasons for the existence of such a difference.

The effect of the winds on the temperature of a place is still more obvious. It is a common observation that the thermometer is more or less raised or depressed by every change of the wind. But there is a great difference in this respect between the lower and higher latitudes. In the former a change of wind rarely raises or depresses the thermometer more than a few degrees, while in the higher latitudes it frequently happens that in a few hours a change of ten or twelve degrees, and even more, takes place. Captain Scoresby mentions an instance of this near the polar ice. On a sudden veering of the wind to the north, the thermometer fell, in sixteen hours, 34°, from + 32° to − 2°. But changes as great as this, so far as such changes are measured merely by number of degrees, occur in the United States of North America, at some distance from the Atlantic. Again, even in the lower latitudes, the change of the wind has a greater effect on the temperature on high table-lands than on low plains. Mr. Dunn states that on the table-land of Guatemala it sometimes, though very rarely, happens, that during the period of the northern winds a cold current produces a difference of 20 degrees in a few hours. A similar phenomenon has never been observed on the low coasts between the tropics.

It is a very common observation, that both cold and heat are more intense when the sky is clear than when it is overcast with clouds. Hence it may be inferred that countries whose atmosphere is more loaded with clouds and vapours than that of others in the same parallel, must have warmer winters and colder summers. This difference is observed all over the world, and from it arises the difference of climate in maritime and continental countries. It is even observed in countries which are at no great distance from one another, as in England and Holland. In England the mean temperature of the summer and winter is said not to differ more than 22° of Fahrenheit, while on the opposite shores of Holland it amounts to 27°, the winters there being a little colder and the summers somewhat warmer than with us. On this however we must observe that even supposing the mean temperature of a large tract of country to be ascertained, which, as is well known, never has been done, there is no very great propriety in comparing the mean temperature of a country of the form and position of England with one of the form and position of Holland. If two points under the same latitude, and both near the sea were taken on the opposite coasts of England and Holland, the difference, whatever it might be, would obviously be owing to the difference in the tracts of country contiguous to the respective places, to the winds, and to the hygrometrical state of the atmosphere. Before any safe conclusion could be drawn, all these conditions should be known. There appears no doubt however that the difference in the mean temperature of the two seasons increases as we proceed farther east in the European continent; and it is equally certain that it depends mainly on the hygrometrical state of the atmosphere, which again in a great degree depends on the winds.

Since the time of Franklin, the attention of observers has been drawn to the effects which the temperature of one country has on that of contiguous countries. In calm weather that effect is probably so small as not to be perceptible. But whenever a wind is stirring, it brings the colder or warmer air from one country to the other, and thus lowers or raises the temperature of that country to which it blows. This effect is very perceptible on the eastern shores of England, with respect to the easterly winds. In the latter part of the spring or early in summer, these winds, before they reach England, pass over the still chilled and damp surface of the great plain of Northern Germany, and blight the already advanced vegetation of our eastern counties. On the contrary, in autumn the same winds pass over a sandy soil, which during the summer has acquired a considerable degree of heat, and the air brought over by them is warm enough to raise the thermometer several degrees. A still more remarkable instance is mentioned by Poeppig, in his 'Travels through Chile, Peru, &c.' In the southern districts of Chile, the eastern winds, called there los Puelches, when they blow in spring (September) are so cold that they depress the thermometer in a short time 15 or 18 degrees; but towards the end of the summer (February) they raise it nearly as much. He attributes naturally enough the first effect to the chain of the Andes being covered with deep snow during the spring, and the second to the high temperature to which the air upon the sandy plains of the Pampas of Buenos Ayres is raised during the summer months.

Considering the great effect which the temperature of countries contiguous to one another exercises on their respective climates, we may presume that a similar effect is produced by seas similarly situated. This has been long ago shown by the observations made on the regular change of the land and sea breezes in warm countries, and by the explanation of this phenomenon, which is obvious and simple. But it has only been recently ascertained that the proportion between the temperature of the sea-water and the atmosphere above it is not every where the same, but that in some parts the sea-water is warmer than in others under the same latitude. Now the temperature of the water must in some degree affect the temperature of the atmosphere, and this atmosphere, when brought into contact with the air of the land by the winds, must produce a change in its temperature. This consideration may sufficiently explain why the countries round the Mediterranean enjoy a much milder climate than all others placed under the same parallel. It is now ascertained that the temperature of the water of the Mediterranean Sea is from 4° to 5° higher than that of the Atlantic in the same parallel. This may perhaps lead us to the explanation of the greatest anomaly of climate which exists on the globe—we allude to the great difference of temperature existing between the western countries of Europe and all the other countries of the globe lying in the same parallel.

Those who had the first opportunity of observing the difference in temperature between western Europe and the eastern coasts of North America were natives of western Europe, and of course they considered the climate of their own countries as constituting the rule, and that of North America as the exception. They accordingly attempted to explain this phenomenon by reference to some peculiarities which characterize North America as a continent, such as the increase of its breadth towards the poles, the stretching out of the continent so far to the north, its large rivers and lakes, &c. But when the temperature of Asia and the eastern countries of Europe was ascertained by observation, it appeared that their temperature differed as much, and in many places still more, from that of the western countries of Europe than North America does. The climate of America may therefore be considered as the rule, and that of Europe the exception. Still the question remains, to what peculiar circumstance it is owing that the temperature of Western Europe differs from that of America and the countries lying farther east in the same latitude by 8° or 10°.

We venture to offer an opinion that the Gulf Stream is the most active, if not the only, cause in producing this difference. This remarkable current stretches across the Atlantic between Cape Hatteras, in North America (35° N. lat.), and the Azores, forming nearly in the middle of the Northern Atlantic a lake of warm water, which, according to the calculations of Major Rennell, is not inferior to the Mediterranean in extent. The temperature of its water is from 3° to 10° higher than that of the surrounding sea. The temperature of the superincumbent air is likewise several degrees higher than it is farther to the west and south, but less so when compared with those portions of the Atlantic which lie farther to the east and north-east. We think that this last difference is due to the strong gales which are almost continually experienced in navigating the Gulf Stream, but more especially on its borders; they blow most frequently from the south-west and west. Winds blowing from these quarters are by far the most prevalent in the Northern Atlantic, and it is observed that even on the coast of Western Europe they still preserve the character impressed upon them by the gales of the Gulf Stream. They do not blow equably like the other winds, but in abrupt gusts, with short intervals of calm. These winds appear to waft the warmer air of the Gulf Stream over the whole of the coasts of Western Europe from Cape Finisterre as far as North Cape; they even penetrate through the wide gate between the Harz mountains and the Scandinavian ranges into the recess of the Baltic, and their effects extend to the very plains of Russia, where they are met by the prevailing north-eastern winds and stopped. All the countries within the range of these winds enjoy a much more favourable climate than those to which they do not extend.

It may here be objected, that as the Gulf Stream approaches much nearer the coast of North America than that of Europe, and as the temperature of its water is also highest there, such an effect as is here described should rather apply to the New than to the Old Continent. But, in the first place, the gulf stream along the coast of America is of comparatively inconsiderable width, being opposite Charleston only from 60 to 63 miles across; and, secondly, its waters in their whole course along that coast lose very little of their temperature. At Cape Hatteras, after a course of 900 miles, the stream has only lost 3° Fahr. of warmth. From this point it turns to the east, and the decrease of temperature begins to be somewhat greater. Yet even opposite the great bank of Newfoundland, after a course of 1300 miles through 15° of latitude, its waters have lost only 5° Fahr. of warmth, and the temperature in this part is from 8° to 10° above that of the adjacent seas. The decrease of temperature begins to be most considerable about the middle of the Atlantic. Now, when we consider that on the eastern coasts of North America likewise the western and south-western winds prevail, it follows that by far the greatest portion of the warm air derived from the evaporation of the Gulf Stream must come to those countries which lie to the leeward of these winds. The parts of North America, however, to the east of the Appallachian range, seem also to feel in some degree the heated air of the Gulf Stream; since it has been proved by Darby that they have a temperature by several degrees higher than the parts in the same latitude to the west of that range.

Another anomaly in temperature occurs in the countries which form the most southern part of the American continent. Humboldt has compared a considerable number of observations, from which it appears that south of 48° the mean temperature of South America is from 12° to 18° lower than that of those parts which lie in the same latitude. North of 48° S. lat. this difference is still considerable, but it gradually diminishes as we approach the tropics. At about 30° it seems to disappear entirely. It is not easy to account for this difference. It was formerly supposed that the ice enclosing the South Pole extended to a much greater distance from it than that which surrounds the North Pole. But Captain Weddel found very little ice in 74° 15′ S. lat.; and our whalers always find it in great masses within the same distance from the North Pole. Besides this, in the northern hemisphere, considerable icebergs advance as far as 40° 45′ N. lat., whilst in the southern hemisphere Captain Weddel says that there is no fear of falling in with ice north of 55° 20′. Many persons suppose that the peculiar form of South America, which narrows towards the south, and stretches out in the form of an acute angle, may be sufficient to explain this phenomenon; but though we admit that this diminution of the surface of the land may have some effect, it can only be a slight one, and, in our opinion, is not by any means sufficient to account for so great a difference in temperature.

There are other circumstances, besides those enumerated, which affect the general temperature, but their influence is confined to small tracts. Thus the temperature of some places is considerably raised or lowered from their being situated on the southern or northern declivity of a high range, or in a narrow valley, or from their being entirely or in a great part surrounded by water. Even the existence of large forests has some influence on the temperature of contiguous places. But as the influence of such circumstances is local, it may be sufficient here to indicate it.

The circumstances which tend to increase or to depress the general temperature of a country being so numerous, and their effect (in producing which several of them often co-operate) being in some instances very great, it often happens that the actual temperature of a country differs considerably from that which might be inferred from the latitude in which it lies. To show therefore what countries, situated under different parallels, have an equal or nearly equal temperature, the isothermal lines, or lines of equal temperature, have lately been introduced.

The second chief constituent of climate, the moisture of the air, appears under the form of rain, vapour, fog, and dew. The laws according to which moisture is distributed in the atmosphere of the globe are nearly unknown, few attempts having been made to ascertain them, with the exception of the rain, which is of a more distinct nature than the other phenomena. We shall limit our observations to rain.

There are extensive tracts of this globe on which a drop of rain is never known to fall, or only at intervals of many years, and then only in small quantities. These countries are always found near the tropics, sometimes extending on both sides of these circles, but often only on the side towards the poles, which circumstance is probably to be ascribed to peculiar localities. These countries may be said to run like two belts round the globe, dividing the countries on each side of the equinoctial line from the temperate zones, as Posidonius very correctly stated. It is only where mountain-ranges exist, that these belts of rainless regions are interrupted. Beginning with the Old Continent, we find in Africa the Sahara or Great Desert, on the southern borders of which the rains cease at about 16° N. lat. and on the north begin at about 28°. Proceeding farther east, the southern rains cease in the countries on the banks of the Nile between 18° and 19°, and the northern begin between 27° and 28°. Passing the Gulf of Arabia we find the Tehama, or low coast of Arabia, which is destitute of rains; but we do not yet know how far to the south or north the rainless region extends. The high table-land which backs this coast on the east is said to have annually some rain, but we have no account of this region on which we can rely; it may be that it owes this advantage to local peculiarities, especially to its elevation. Farther east the rainless region extends through Meckran, a province of Beloochistan, the desert of that country, and over the delta of the Indus. Here it appears not to comprehend more than 4° of latitude. From this point it turns to the north-east and extends to 30° N. lat., comprehending the Indian desert to the very base of the Himalaya mountains. Behind this range extends the high table-land of Tibet, which also has no rain. But at the eastern extremity of the Old Continent, in China, there is no rainless region, which may perhaps be owing to the circumstance that all the parts of China between 22° and 30° N. lat. are traversed by the high mountain chains of the Nan-ling and Yoo-ling, and consist of a continual succession of ridges and valleys.

The countries of the Old Continent contiguous to the southern tropic are not well known, but that part of Southern Africa, on the shores of the Atlantic, which extends to the north of the Gareep, or Orange River (between 24° and 28° S. lat.), is said to be a sandy desert, with little or no rain. Towards the Indian Ocean, Africa is traversed by several mountain-ranges, and consequently has there a somewhat moister climate. Australia also appears to be subject to the same disadvantages. The long droughts, sometimes continuing several years together, which occur in our colony in New South Wales, indicate that a great portion of Australia must be reckoned among the countries which are entirely or nearly destitute of rain.

In America the rainless region near the tropics is less distinctly marked, probably on account of the comparatively narrow width of that continent near the tropics, and other local peculiarities; yet such a region exists in both hemispheres. In the northern it seems to occupy the coast of the Gulf of Mexico, between 24° and 26°, and to extend westward, comprehending the arid plains of Monterey and Chihuàhua, till it reaches the northern portion of the Sierra Madre Mountains, whose northern extremity it surrounds. It then stretches along both banks of the Rio Gila to the Gulf of California, where it however does not terminate, as the peninsula of California has no rain north of 23°. The countries of South America, near the tropic of Capricorn, rise suddenly from the Atlantic Ocean to a considerable height, and take the form of high table-land, traversed by mountain ridges. These parts of course are not without rain: but nearly midway between both oceans the country sinks considerably lower, and the Grand Chaco or Great Desert occurs, in which rain seems to be very rare. This extensive plain is divided from the Atlantic by a mountainous country, and from the Pacific by the high range of the Andes. In both these mountainous regions rains are frequent; but on the coast of the Pacific, though it presents a very uneven surface, not a drop of rain is known to fall all the year round between 23° and 27° S. lat. This barren tract consists of the Chilese department of Copiapò and the Bolivian province of Atacama.

These two belts of rainless regions, which on the land are frequently narrowed or interrupted by local circumstances, have a more distinct character on the ocean. Rain seldom falls within the range of the trade winds, except on their very borders, both towards the region of the calms and towards that of the variable winds.

Between the two belts formed by the rainless regions are situated those countries which are subject to the equatorial rains. The ocean also has these rains in a small degree in those parts which constitute the region of calms. Here the phenomena of the atmosphere succeed one another with great regularity. The sun rises in a cloudless sky: towards noon some faint clouds appear near the horizon, which rapidly increase in extent and density, and are soon followed by thunder and violent gusts of wind, accompanied by heavy rains of short duration: towards evening the clouds disappear, and the sun sets in a serene sky of a deep blue hue. It does not appear that this state of the weather is at all affected by the seasons.

Those parts of both continents which lie on each side of the equator between the rainless regions, have the greatest quantity of rain, and this occurs at certain periods of the year, whence these rains are called periodical rains. The season of the rains depends on the position of the sun. It begins some time before the sun reaches the zenith of a place, and continues for some time after it has passed it; hence the rainy season varies with the difference of latitude. Though the observations which are requisite to determine this point are far from being sufficiently numerous, it would appear that these countries which are near the equator are never for many days altogether without rain, and that there the rainy season, which occurs when the sun passes over the zenith, is only distinguished from the other parts of the year by a greater continuance and a greater abundance of the rains. In the countries more than 5° of lat. distant from the equator, the dry and wet seasons are distinctly marked. The rains begin either immediately or not many days after the sun in its progress towards such a place has passed the equator. They are heaviest when the sun approaches the zenith of the place, after which they continue with less abundance for an equal or even longer time. In general the rains are more abundant in the first than in the second half of the season.

Countries that lie between 5° and 10° of lat. have commonly two rainy and two dry seasons. The greater rainy season occurs when the sun in its progress to the nearest tropic passes over the zenith, and lasts from three to four months. The less rainy reason occurs when the sun on its return from the nearest tropic approaches the parallel of the place. The rains then last only from six weeks to two months, and are much less abundant and continual. Coun[illegible]re than 10° or 12° from the equator have only one [illegible] one dry season: the first begins when the sun approaches the nearest tropic, and ends some time after, when, in its course from the tropic, it has passed the parallel of the place. It lasts from four to six months. Such is the course of the rainy and dry seasons in these countries when their regularity is not disturbed by local circumstances, which sometimes effect considerable changes. The most remarkable deviation from this order occurs in India, where the period of the rainy and dry season is not regulated by the position of the sun, but by the change of the monsoons.

The periodical rains differ from the variable rains, which occur in the countries that lie without the tropics, not only in the greater regularity of the time at which they fall, but also in their abundance. The quantity of water which pours down between the tropics in one hour is often greater than that which falls in these latitudes in three or four hours. There is however an erroneous opinion prevalent respecting these rains: it is generally supposed that they continue for many days without interruption, but this is not the case: a day in which the rains fall without interruption from morning to evening is of much rarer occurrence between the tropics than with us; the sun usually rises in a cloudless sky: two hours before noon the clouds begin to appear, and at noon the rains set in. They then frequently pour down in torrents for four or five hours; but towards sunset they cease, the clouds suddenly disappear, and not a drop descends during the whole night. As the abundant rains, especially when the rainy season sets in, frequently cover the level and low country a foot deeper with water, the atmosphere of such tracts is continually loaded with vapours and exhalations during that period, which render the stars invisible at night, and are doubtless the principal cause of the unhealthiness of those countries.

The parts which lie between the rainless regions and the pole are subject to the variable rains. There is not a single day in the year in which it has not rained, or may not rain, and the rains are perhaps as common in the night as in the day. There are certainly differences, both in the quantity and in the time of the rains in these countries; but this difference can only be ascertained by comparing long sets of exact observations; and such exact observations are still wanting, except for the western parts of Europe. Comparing these observations, one would suppose that the countries south of 45° N. lat., with few exceptions, have also a kind of rainy and dry season, the former occurring in autumn and winter, and the latter in spring and summer. In summer frequently two or three months pass without a single drop of rain falling. In the countries north of 45° such a difference is not observed: there the greatest quantity of rain seems to fall in the summer, except in England, where the summer is the driest part of the year. The quantity of rain however decreases as we advance from the shores of the Atlantic to the inland parts of the European continent. The rains become again more abundant when we reach the plains of Eastern Europe, near Petersburg and Moscow, which may perhaps be owing to the circumstance, that here the winds proceeding from the Gulf Stream meet those which blow from the Ural Mountains and the great sandy deserts. These rules, derived from observations made in Europe, will probably not hold good for other parts of the globe, because the temperature of Europe forms, as we have observed, a great anomaly. Accordingly we find that the few meteorological observations which have been made in the United States are far from confirming these rules.

In estimating the climate of any given country, there are other phenomena which require notice; but their effect on climate has not been ascertained with any great precision, and there is reason to think that it cannot be very great, though electrical phenomena are thought by some to have considerable influence. They certainly change the condition of the atmosphere for a short time, which is most obvious in those violent thunder-storms within the tropics known by the name of typhons.

CLIMAX, (κλῖμαξ, a step or ladder) commonly called a figure of rhetoric, but properly only an artifice of style; for a figure or trope is a use of words in some other than their natural or literal sense. In accordance with the primary meaning of the Greek word, a climax in composition is a mode of expression by which the writer mounts, as it were, from one clause to another, as if he were climbing a series of steps. In other words, each clause expresses a higher degree of that which is stated in the preceding clause. The three words which Suetonius records to have been uttered on occasion of one of his victories by Julius Cæsar—'Veni, vidi, vici,' form a climax. The following sentence addressed by Cicero to Catiline is another: 'Nihil agis, nihil moliris, nihil cogitas, quod ego non audiam, non videam, planeque sentiam' (You do nothing, you attempt nothing, you conceive nothing, which I do not hear, which I do not see, nay, which I do not even feel). 'A gradual progress from small to great,' observes Lord Kames (*Elements of Criticism*, chap. iv.), 'is not less remarkable in figurative than in real grandeur or elevation. Every one must have observed the delightful effect of a number of thoughts or sentiments, artfully disposed like an ascending series, and making impressions deeper and deeper; such disposition of members in a period, is termed a *climax*.' In another passage he makes an attempt to explain the effect asserted to be thus produced. 'If a number of objects of the same kind,' he says, (chap. xviii. §. 2,) 'differing only in size, are to be ranged along a straight line, the most agreeable order to the eye is that of an increasing series; in surveying a number of such objects, beginning at the least, and proceeding to greater and greater, the mind swells gradually with the successive objects, and in its progress has a very sensible pleasure. Precisely for the same reason, words expressive of such objects ought to be placed in the same order.' The effect of a climax would seem to be more simply accounted for by the consideration of the state into which the mind of a reader or hearer is necessarily thrown by any emphatic assertion in a vehement or impassioned discourse; he naturally expects that the next assertion, if another is to follow, will involve something still stronger or more exciting—that it will constitute some addition to what has been already said—else why should it be uttered at all? He is gratified, of course, when this expectation is fulfilled, and would be the reverse if it were not. The latter effect is produced by what is called an anti-climax, the slight shock of the disappointment occasioned by which is sometimes, in suitable circumstances, made available to produce the emotion of the ludicrous. Lord Kames (chap. xviii. § 1) reckons what he calls a *climax in sound* and defines to be the 'order of words or members gradually increasing in length,' as one of the beauties of language. One example of this which he gives is the following from Cicero: 'Quicum quæstor fueram; quicum me sors consuetudoque majorum; quicum me deorum hominumque judicium conjunxerat.' When the climax in sense and the climax in sound coincide in the same passage, he afterwards observes (chap. xviii. § 3), 'the concordance of sound and sense is delightful; the reader is conscious not only of pleasure from the two climaxes separately, but of an additional pleasure from their concordance, and from finding the sense so justly imitated by the sound.' We may remark that, although an anti-climax, except to produce a ludicrous effect, must always be regarded as a stumble in composition, and is therefore to be avoided, a climax is the favourite ornament of rather an artificial and mouthing style of rhetoric. A natural writer will commonly come out with the strongest thing he has to say at once, instead of cautiously advancing to it by this sort of measured dance. (For an example of climax from Demosthenes, see Demetrius Phal. Περὶ Ἑρμηνείας.)

CLINTON, DE WITT, has a claim to biographical notice chiefly as the persevering promoter of the project for the formation of the great canal from lake Erie to the Atlantic. He was born in 1769, at Little Britain, in the state of New York. His mother was one of the distinguished Dutch family of De Witt; and his father, who was of English extraction, served with great distinction as major-general in the army of the United States during the revolutionary war. De Witt received his education at Colombia College, New York, and was admitted to the bar. In 1797 he was elected, by the democratic party, to the state legislature of New York; having previously officiated for several years as secretary to his uncle George Clinton, as well as to the regents of the university, and board of fortifications, of New York. In 1801 he was elected a member of the senate of the United States. He afterwards filled the office of mayor of New York until 1815, when his retirement was occasioned by the violence of political parties. During the period between 1817 and 1826, he was several times elected governor of the state of New York by the zealous exertions of the democratic party. He was a member of most of the literary and scientific societies of the United States, and of several similar institutions in Europe. His productions consist of his speeches made on various occasions in the performance of his official duties; papers read before literary and benevolent societies; correspondence concerning the canal; judicial opinions, and various fugitive compositions. His services to his native state were important, and his character, as a lover of science and polite literature, was adorned by a generous benevolence. He died suddenly in 1828, and was interred with great public demonstrations of respect.

CLI'NUS, a genus of fishes of the section Acanthopterygii and family Gobiadæ. It forms one of the subdivisions of the Blennies, the species of which may be distinguished by their having several ranges of short pointed teeth, the teeth of the external range being the largest. The dorsal fin is either continuous and even, or, in some, with the anterior rays separated from the posterior by an emargination. Like the true Blennies, these fishes have small fimbriated appendages over the eyes. [BLENNIUS.]

CLIO (Zoology), **CLIO TRIBE, CLIO'NIDÆ**, a family of naked marine mollusks, placed by Cuvier as the first of his class *Pteropoda*. Lamarck also arranges them under the Pteropods, which he makes an order, but gives them a situation immediately after the *Hyalæidæ*. De Blainville unites the *Pteropoda* and *Gasteropoda* of Cuvier in one class *Paracephalophora*, under which the *Pteropoda* form an order with the name of *Aporobranchiata*, which is divided into two families; the first, *Thecosomata*, being provided with a shell, and the second, *Gymnosomata*, comprising those Pteropods which have none. Rang follows this last arrangement, still retaining Cuvier's term Pteropoda, but not rejecting De Blainville's, and making the *Clios* of Férussac synonymous with the *Gymnosomata* of De Blainville, and the second family of the class *Pteropoda*. The following is De Blainville's definition of his *Gymnosomata*:—

Body of an elongated form, subconical, completely naked; two bundles of tentacular suckers at the mouth; no tooth in the upper lip; a small lingual plate bristled with spines.

Rang thus defines the family:—Animal with the head distinct; no intermediate lobe, but one or more fleshy appendages in place of it; a muscular envelope or mantle.

Genera, Clio. (Clione, Pallas.)

De Blainville, who says that he characterized the genus from his own observations, gives the following definition:

Body free, naked, more or less elongated, a little depressed, attenuated abaft (aminci en arriere), without any other fins than the lateral appendages. *Head* very distinct, provided with six long retractile tentacula, divided into two groups of three each, and capable of being entirely concealed in a species of prepuce bearing a small tentaculum on its external side. *Mouth* entirely terminal and vertical. *Eyes* sessile, nearly supernal. A sort of sucker or rudiment of a foot under the neck, between the roots of the fins. *Vent* and termination of the *generative apparatus* in a single tubercle, situated at the right side of the neck, at the junction of the fin with the trunk. *Organs of Respiration?*

Rang thus describes the genus:—Animal elongated, enveloped *in a membranous and very contractile mantle*, with a head furnished with many long conical tentacula, which are retractile, and separated into two groups, and can be withdrawn at pleasure into small cavities destined for them. *Branchiæ* in form of a vascular net-work carpeting (tapissant) the fins. *Mouth* terminal. *Eyes* sessile? Three membranous appendages to the ventral part, and corresponding to the base of the fins. *Vent* and *organs of generation* situated in a tubercle on the right side.

Cuvier, who paid some attention to the Clios, thus defines the genus in the last edition of the 'Règne Animal:'—The Clios have an oblong membranous body *without a mantle*, the head formed of two rounded lobes, whence spring small tentacula. They have two small fleshy lips and a tongue (languette) at the front of the mouth, and the fins are provided with a vascular net, which performs the office of *branchiæ*. The *vent* and *generative orifice* are under the right gill. Some say that they have eyes. The mass of the viscera does not nearly fill the external envelope. The stomach is large, the intestine short, and the liver voluminous.

The principal discrepancies in the above definitions are the following:—1st. As to the mantle. De Blainville does not notice it; Rang expressly mentions a membranous and very contractile one; and Cuvier directly denies its presence. There is not much real contradiction on this point. It may not be strictly correct to call the contractile sac which envelopes the Clio a mantle, any more than it would be to give that name to the test which is the investing integument of the *Ascididæ;* but all three authors must be taken to mean that the internal parts of Clio are surrounded and protected by a highly contractile integumentary envelope. 2nd. As to the organs of respiration. These appear to have entirely escaped the observation of De Blainville, while Cuvier and Rang point out their position and describe their structure. 3rd. As to the eyes. De Blainville expressly describes these organs and their position. Rang says eyes sessile? with a query, and Cuvier merely observes that some attribute to them eyes. That the Clios may be sensible of light is highly probable; but any thing like a well developed eye properly so called is not very apparent, in *Clio Borealis* at least.

a. Species whose tentacula are well known.

Of these, *Clio Borealis* and *Clio Australis* will serve as examples. The former, which appears to be the same with *Clio limacina* of Phipps, *Clio retusa* of Fabricius, and *Clione papilionacea* of Pallas, is well known to the whale-fishers and others under the name of '*whale's food.*' The species swarms in the northern seas, and indeed so plentiful are they that they form a principal part of the food of the whale-bone whales. Captain (now Sir W. E.) Parry found it in great abundance in all parts of Baffin's Bay and Davis's Strait, in the neighbourhood of ice. (*Supplement to Captain Parry's first Voyage.*) Captain James Ross observes that it is very numerous in most parts of the Arctic Ocean, but less abundant in Regent's Inlet and the Gulf of Boothia. When the weather is calm, they come in myriads to the surface for the purpose of respiration; but scarcely have they reached it, when they again precipitate themselves towards the bottom. Cuvier, who gives this account of their habits, adds, that the sea is so glutted with them in certain seasons, that the whales, so to speak, cannot open their mouths without ingulphing thousands of these small mollusks.

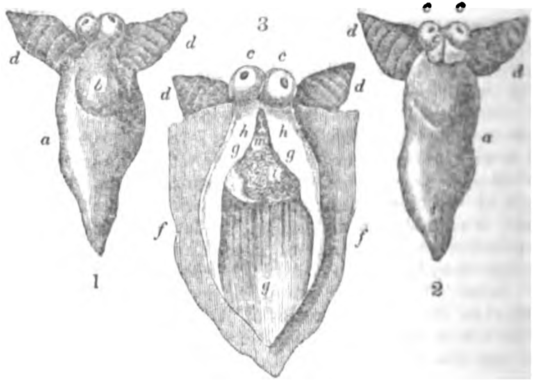
Integument, a delicate, demi-transparent, soft skin which covers a second tunic. This last is thicker, and presents longitudinal and very sensible muscular fibres, which come from two principal bundles attached to the sides of the neck. The effect of these fibres must be to shorten the general envelope of the body, and to approximate its form to a spherical shape. Cuvier, who gives the above description, adds, that he knows not with what the interval between this fleshy tunic and the mass of the viscera is filled in the living state; but observes that it is certain that these do not occupy the half of the area which the tunic incloses; and conjectures that there may be a liquor diffused there, or perhaps only a quantity of air which the animal can compress at pleasure when it would sink in the water, and dilate when it would rise.

Digestive Organs.—The mouth is between the bases of the two tubercles of the head. Below it are two triangular tentacula, which form, as it were, two small wings between the two large ones. The opening of the mouth is triangular; and within are seen some longitudinal wrinkles, which Pallas and Fabricius appear to have taken for teeth, but which have no hardness, and are entirely fleshy. The viscera are connected by vessels and cellulosities which unite them in a small packet situated near the neck. The liver covers the greatest part of them, with the exception of an angle which is occupied by the testicle and ovary. The *œsophagus,* of a fair length, descends from the mouth through the neck, and is dilated into a stomach towards the bottom of the mass. Thence the intestinal canal, after having made one fold, proceeds directly to the vent, situated under the gill of the left side. The *liver* is composed of many lobes and lobules, and envelopes the stomach and a great part of the intestinal canal. Two long and straight salivary glands float at the sides of the œsophagus: their excretory ducts are inserted in the mouth. (Cuvier.)

Brain, Nervous System, and Senses.—The brain consists of two lobes placed at the origin of the œsophagus. From each of these springs a small filament, which swells into a large ganglion that unites itself to its correspondent under the œsophagus. These two ganglions give out each their filaments to the neighbouring parts. Two of these filaments, one on each side, swell again into ganglions, which, uniting together by a new filament that traverses upon the œsophagus, form there a second collar joined to the first beneath: they give out a filament, which is twice swollen or knotted, and it is from these small knots of medullary matter that the different nerves arise. No eye could be perceived, nor any particular organ of the external senses, except the common and general organ of touch. (Cuvier.)

Respiratory and Circulating System.—Each gill gives off a vein, which, uniting to its correspondent in the shape of a Y, forms the trunk which reaches the heart. This last, situated in its pericardium on the left side of the mass of viscera, gives out, doubtless, arteries for the whole body, but they could not be followed out. (Cuvier.)

Organs of Reproduction—Very much resembling the Gastropods, and uniting, like them, the two sexes. The ovary gives off a delicate and short oviduct, which reaches the testicle. This last, which at its origin resembles a cæcum, lessens by degrees into a deferent canal, and terminates at a small round purse, which fills the left tubercle of the head, and has its exit near the neck. It is undetermined whether the straight and firm part which terminates the deferent canal is the penis, or whether that organ is hidden in the small purse above noticed. At the side of this purse is another oblong one, analogous to that which is termed the bladder (la vessie) in the ordinary gastropods. (Cuvier.)



[Clio Borealis.]

Fig. 1, Clio Borealis, view of the back; *a*, the body; *b*, the viscera, seen through the common integuments; *c*, the tubercles of the head, and the holes wherein the three tentacula on each side are withdrawn; *d*, *d*, gills and fins. Fig. 2, the same, view of the belly; *a*, *c*, *d*, indicate the same parts as in fig. 1; *e*, the two tentacula placed before the mouth. Fig. 3. *c*, *d*, indicate the same parts as in the two former figures; *f*, *f*, the external tunic or skin; *g*, *g*, the internal tunic or fleshy pannicle; *h*, *h*, the principal bundles of its fibres; *i*, the mass of viscera; *m*, the principal vein of the gills.

The finest specimen of *Clio Borealis* we ever saw is in the Museum of the Royal College of Surgeons (*Gallery Nat. Hist.*, 161 A.), presented by Captain (now Sir John) Ross.

The figures and description above given (Cuvier's) are taken from an individual which had its tentacula, &c., withdrawn.

β. Species without tentacula? and whose cephalic enlargement (renflement) is separated from the trunk by a sort of narrow and very distinct thorax. (Genus *Cliodites* of Quoy and Gaimard.)

Example, *Clio* (*Cliodites*) *Caduceus.* De Blainville observes that this species is too incompletely known to allow of a satisfactory conclusion as to what it is; and he even thinks that it may be identical with the *Clio Australis* of Bruguières.

Pneumodermon.

Animal oblong, subcylindrical, divided into two very distinct parts, the anterior conical, the posterior oval. The fins placed near the separation of these two parts, and presenting between them, and on the ventral side, a small membranous appendage. *Mouth* at the extremity of a sort of retractile proboscis, having, at its base, two bundles of tentacula, each terminated by a small disk or sucker. *Gills* situated at the posterior part of the body, and disposed somewhat in the form of two C's placed back to back, ƆC, and separated by two small bars. *Vent* on the right, and a little anterior to the gills. Orifice of the *organs of generation* in a common tubercle, situated at the root of the fin of the right side. Example, *Pneumodermon Peronii.* This is about an inch in length, and was discovered in the Atlantic ocean by Péron. The genus was established by

Cuvier. De Blainville founded his character upon many well-preserved individuals brought home by MM. Quoy and Gaimard from the expedition under Captain Freycinet, and gives Australasia as the locality of the species.

CLIO. [Muses.]

CLITE'LLIO. [Lumbricus.]

CLITHEROE, a market town, a parliamentary borough, and a parochial chapelry in that part of the parish of Whalley which is in the higher division of the hundred of Blackburn, and in the northern division of the county palatine of Lancaster, 216 miles N.N.W. of London, and 26 S.E. of Lancaster. Its population in 1831 was 5213, two-thirds of whom are employed in trade, and the rest in agriculture. Clitheroe is a borough by prescription; its earliest known charter is dated in the time of Henry de Lacy, who died in 1147; but it did not send members to parliament before the first year of Elizabeth. The late Boundary Act extended the parliamentary borough to the neighbouring chapelry of Downham, and the four townships of Whalley, Wiseyall, Pendleton *cum* Henshorn, and Little Milton *cum* Colcoats, and reduced the two members to one. The town is governed by two bailiffs, chosen annually by the burgesses and freemen. Three courts are held here, viz., the court-baron, the court-leet, and a court of inquiry, at which the bailiffs preside. They are held in the New Moot-hall, a modern building of the Gothic order, with a spire sixty-two feet high.

The name of this town, or, as it was antiently spelt, Cliderhaw, is descriptive of its situation, a hill by the waters. The family of De Lacy, who came over with the Conqueror, built the castle, consisting merely of a keep, with a tower and arched gateway, not for a residence, but as a fortress. It was also used for the purpose of receiving tribute from the feudatories within that manorial district, still called the Honor of Clitheroe. Within the walls by which the castle was inclosed, where a handsome house now stands for the bailiff, was a chapel dedicated to St. Michael, which disappeared when the fortress was dismantled in 1649. Prior to this, the Honor of Clitheroe had vested in the crown, and Henry VI., after he was deposed, concealed himself there after the battle of Hexham, but was discovered by the Talbots of Bashall and Colebry, who carried him to London with his legs bound to the stirrups of his horse. The Honor of Clitheroe was, for nearly three centuries, a part of the possessions of the duchy of Lancaster, till Charles II. granted it to General Monk, Duke of Albemarle, from whom it has descended to the present proprietor, the Duke of Buccleuch.

The church of Clitheroe is an ancient structure, with a fine Saxon arch between the nave and choir; it is dedicated to St. Michael, the patron of the castle church. The living is a perpetual curacy under Whalley, of which Earl Howe is patron. Among the monuments of this church is a brass plate to the memory of Dr. John Webster, the astrologer, who obtained celebrity by detecting the impositions of witchcraft in the seventeenth century. One of the incumbents was the Rev. James King, whose son circumnavigated the globe with Captain Cook. The Roman Catholics, the independent dissenters, and the methodists, have places of worship, with Sunday-schools attached, in which nearly 700 children are instructed. Contiguous to the churchyard is a grammar-school, founded and endowed by Philip and Mary in 1554, at the recommendation of Bishop Bridgman, who drew up the statutes. Its concerns are managed by six governors, who appoint the master and usher, subject to the approval of the Bishop of Chester. The income is 452*l.* 8*s.* 8*d.*, arising from the rectorial tithes of the parish of Almondbury, and lands and messuages in Yorkshire. There are twenty scholars, who are educated in the classics, and writing and arithmetic, by whom an annual remuneration is made to the masters, under the name of a cock-penny; besides which fees, the salary of the head master is 200*l.*, and of the under master 100*l.* The rooms of the grammar-school have been used since 1816 as a church Sunday-school, in which 350 children are instructed on the Madras system.

Clitheroe was until recently a place of little trade; but extensive print works and cotton manufactories have been established, which, along with the lime-kilns, find ample employment for the increasing population. The neighbourhood abounds with limestone, for which there is a great demand, as it can now be conveyed by water to any part of the kingdom. The houses of Clitheroe are built of stone, the streets are well paved, and the town is well supplied with water from springs. There has been a weekly market from the time of the Conquest. It is now held on Tuesday, though Saturday is the day for the chartered market. Every alternate week there is a cattle market. Fairs are held March 24 and July 21, for horned cattle and woollen cloth; and the fourth Saturday after Michaelmas-day for cattle, horses and woollens. (*Communication from Lancashire.*)

CLITHON. [Neritidæ.]

CLITUS, or CLEITUS. [Alexander III.]

CLIVE, ROBERT, LORD, was born on the 29th of September, 1725, at Styche, near Market Drayton, Shropshire. His family was respectable, but poor. He was sent to several schools, but distinguished himself in all of them rather by a love of mischief and a fearless disposition than by any aptitude or love for learning. He was sent to India, and arrived at Madras, in the civil service, as a writer, in 1744. Three years after he quitted the civil service of the Company for the military, which suited him much better. In 1748 he distinguished himself at the siege of Pondicherry, and shortly after at the taking of Devi-Cotta, in Tanjore, on which occasion his superior officer recommended him to the notice of the Company and British government. Coming into contact with the French (with whom, and not with the natives of India, the main struggle lay) he beat them under their veteran commanders. The taking of Arcot, and the decisive victory gained by the British there, were chiefly owing to this young and comparatively inexperienced officer. On his return to England in 1753 for the recovery of his health, he was highly complimented by the Directory of the East India Company. In 1755 he went again to India as governor of Fort St. David, and with the rank of lieutenant-colonel in the king's service. Soon after his arrival, in conjunction with the naval commanders, Watson and Pocock, he reduced the dangerous pirate Angria, taking Gheriah his capital, and all his treasures. In the meantime the nabob Sujah-u-Dowlah had attacked the British, destroyed their factories, and barbarously thrown part of his prisoners into the memorable 'Black Hole' of Calcutta. Colonel Clive was then, according to the admission of all parties, the main stav and only hope of the British in India. He sailed at once with Admiral Watson to Calcutta, took Fort St. William, in January, 1757, and following up his advantages, thoroughly defeated and disorganized the Sujah's army. Clive's victories led to a peace highly advantageous to the British power in India, which before this event was dwindling to nothing. A series of intrigues and recriminations followed: Clive accused Dowlah of being wholly devoted to the French interests,—as a cruel tyrant over his subjects,—a man without honour, in whom there could be no faith or confidence. On the other side it was urged that Clive, insatiable of power, influence, and wealth, had from the beginning determined to dethrone that Nabob—that with this view he had engaged in intrigues with Meer Jaffier, one of the Nabob's officers, and with Omichund, a Gentoo merchant, whom, it was said, he afterwards defrauded. In all these transactions the observation of the rigid rule of right is not to be expected on either side. Clive's business was to advance the British power in India, and the Nabob happened to be at once an impediment in his way, and a cruel tyrant, after the fashion of that country. The war that ensued was short and brilliant, for, with a 'handful of men,' Clive gained the great victory of Plassey, and, on the next day, entering Murshedabad in triumph, installed Meer Jaffier, who took the style of Jaffier-Ali-Cawn, in the place of Sujah-u-Dowlah. The deposed Nabob was soon taken, and privately put to death by Meer Jaffier's son. The new Nabob gave Clive a jaghire, or grant of land, which was said to produce 27,000*l.* per annum. Clive being made governor of Calcutta, held the chief command there, and through the rest of British Bengal, for about two years.

In 1759 he destroyed a formidable Dutch armament sent against Bengal. In 1760 he returned to England, where he received the unanimous thanks of the Company, and was created by government an Irish Peer, under the title of Lord Clive, Baron of Plassey. He was returned to parliament for Shrewsbury, and kept his seat in the House of Commons till his death. In politics he was rather liberal, being what was then called a 'moderate Whig,'—but he exercised a prodigious influence on parliamentary elections. Speaking of his title of Lord, he says, in a letter to his friend Major Carnac, 'If health had not deserted me on my arrival in England, in all probability I should have been an English Peer instead of an Irish one, with the promise of a red riband. I know I could have bought the title (which is usual), but that I was above, and the honours I have obtained are free and voluntary.'

After Clive's departure, the affairs of India fell into an apparently hopeless state of confusion, and he was once more sent out (in 1764) as the only man at all likely to retrieve them. Before this last employment he received the order of the Bath, and was promoted to the rank of major-general. In spite of dissensions and intrigues, and an almost general opposition on the part of the *employés* of the Company, both civil and military, he set things in order, and gave security to that broad basis on which the British power has been since raised in India. He, however, made many enemies, whose influence he felt a few years later.

He returned from India on the 14th of July, 1767, with a constitution thoroughly shattered. He was received with the greatest distinction. Five years later (in 1772) his proceedings in India were made the subject of severe animadversion in parliament, and out of doors; and in 1773 a select committee of the House of Commons was appointed to examine into them. The charges presented to the House were most serious, involving even a charge of forgery; but on the great debate, on the 22nd of May, the combat was narrowed into a motion made by Colonel Burgoyne, and seconded by Sir William Meredith—'That in the acquisition of his wealth Lord Clive had abused the powers with which he was intrusted.'

This motion was rejected, and, at five o'clock in the morning, a resolution was passed—'That Lord Clive had rendered great and praise-worthy services to his country.' He was thus acquitted, but the course of the trial was a process of torture to his proud spirit, nor was the form of the acquittal altogether satisfactory. He never held up his head again, and towards the end of the following year he committed suicide. Soon after his first arrival in India, in consequence of a painful disorder, he accustomed himself to take opium, the pernicious doses of which he gradually increased. After his last arrival in England, he suffered from a complication of disorders, and, to alleviate the anguish of the gall-stones, he swallowed opium in greater quantities than ever. His death took place on the 22nd of November, 1774, at his house in Berkeley Square, shortly after completing his forty-ninth year. (*Life of Robert Lord Clive, collected from the Family Papers, &c.*, by Major-General Sir John Malcolm, 3 vols. 8vo., 1836.)

CLIVI'NA, a genus of coleopterous insects of the family Scaritidæ, and section Geodephaga. The technical characters are:—body elongate, somewhat cylindrical; antennæ moniliform, the basal joints rather long (the first longest), the remaining joints short and rounded; palpi with the terminal joint long and pointed; mentum trilobate; thorax nearly square; anterior tibiæ broad and compressed, with two notches externally, leaving three long, pointed, tooth-like processes; the intermediate pair of legs with one of these external processes on the tibia.

Dejean incorporates with this genus that of Dyschirius, but we think without sufficient reason.

These insects are of small size, and live under stones in damp situations, particularly on the margins of rivers, lakes, &c.; their dentated anterior tibiæ enable them to burrow like the Lamellicorn beetles.

Of the genus Clivina but few species are known. In England there are two; the more common is *Clivina fossor* (or *C. arenaria* of some authors). This species is rather more than three-sixteenths of an inch in length, and of a black or brown colour; the legs, antennæ, and palpi, are reddish. *Clivina collaris*, the other British species, is rather less than the one just described. It is black, and has chesnut-red elytra, sometimes with a black dash on the suture.

The species of the genus Dyschirius is distinguished from those of Clivina principally by their having the thorax globular, the terminal joint of the palpi thicker in proportion, and somewhat securiform. The body is generally shorter in proportion, and more convex, or less cylindrical; they are almost always of a brassy metallic colour, whereas the species of Clivina are black or brown, and without any metallic hue.

Of the genus Dyschirius between twenty and thirty species are known. Their habits are much like those of the genus Clivina, but they are less frequently found under stones, and often make cylindrical burrows in the ground in banks at the margin of rivers or other pieces of water. Upwards of twelve species inhabit this country, the largest of which is scarcely more than one-eighth of an inch in length.

CLOA'CÆ, large arched drains, formed under the streets of some antient Roman cities. The most remarkable were the cloacæ of Rome, large portions of which still remain in excellent repair. These cloacæ are doubtless of high antiquity, and tradition assigns their origin to the time of the first Tarquin (Livy, i. 38). According to Livy (v. 55) the chief subterranean passages originally followed the lines of the streets and public places, but in the hurry of rebuilding the city after the Gallic invasion, the old lines of streets were neglected, and the houses were often built across the drains.

The cloacæ of Rome consisted of several branches, which ran in the low parts between the hills; these branches fell into one very large arched drain, constructed of solid blocks of stone, called the Cloaca Maxima, said to have been built by Tarquinius Superbus (Livy, i. 56), and repaired, in latter times, by Cato the Censor and his colleague in office. A portion of this cloaca is visible near the Arch of Janus. It was formerly continued towards the Tiber, passing by the Corinthian peripteral temple, called the Temple of Vesta, close to which it terminated in the Tiber, at a point believed to be the Pulchrum Littus, so called from the sides of the river having a walled embankment, with steps. The arched drain of the Cloaca Maxima is fifteen feet wide, and thirty high (these dimensions include the masonry); with three arches in contact one within another: in some parts there are raised paths along the sides of the cloaca; and in the walls are stone brackets to support the ends of the waste pipes of the fountains. Niebuhr says that the innermost vault forms a semicircle 18 palms* in width, and of the same height. This vault is inclosed within a second, and this again within a third. The stone employed, called peperino, is a greenish stone with black specks. The blocks are 7½ palms long and 4½ high. The same writer is of opinion that the Cloaca Maxima was only constructed to drain the Velabrum and the valley of the Circus Maximus. (*Hist. of Rome.*) In the year 1742 a part of the Cloaca Maxima was discovered in the Forum, at the depth of thirty feet from the surface, constructed in a similar manner to the part which is seen near the Temple of Janus. (Nardini, p. 210, lib. v., cap. vii., regio viii.) Niebuhr, on the authority of Ficaroni, says it was constructed of travertino stone, and he thinks it of greater antiquity than the peperino construction. The only cloacæ or drains for a city which can be compared with the cloacæ of Rome, are the sewers of London; and no city in the world is better provided with this valuable and healthy convenience.

The maintenance of the Roman cloacæ was originally the business of the censors, but afterwards belonged to the ædiles: Agrippa, during his ædileship, made numerous large cloacæ, of which Pliny (xxxvi. 15) has spoken in terms of unbounded admiration. The emperors created officers called curatores cloacarum. The city of Pompeii had cloacæ on a smaller scale.

The etymology of the word cloaca is doubtful. Festus derives it from the verb *colluo*, 'to wash together,' or 'bring together by washing.' (*Encyclopédie Méthodique*, 'Architecture;' *Plan of Rome*, by the Society for the Diffusion of Useful Knowledge; Nardini's *Rome*.)

CLOCK. [HOROLOGY.]

CLO'DIUS PU'BLIUS, a Roman patrician, the son of Appius, first became notorious by introducing himself, in the disguise of a woman, into Cæsar's house during the celebration of the sacred rites of the Bona Dea. For this offence he was tried, but, by the help of his hirelings and dependents, and by bribing the judices, he was acquitted. (Cicero, *Ep. ad Attic.*, i. 12. 16.) Cicero, who was called to give evidence on this trial, made a very unfavourable statement respecting his character, for which Clodius never forgave him. It was chiefly in order to revenge himself on so formidable an enemy, that Clodius took measures to qualify himself for the office of tribune of the people: with this view he got himself adopted into a plebeian family, though with considerable difficulty, and not without the help of Cæsar and Pompey. No sooner was he elected tribune than he applied all his energies to effect the ruin of Cicero. [CICERO.]

In B.C. 57, when Lentulus had brought before the senate a proposal to recal Cicero from banishment, a day was fixed for taking the sense of the people. Fabricius, one of the tribunes, who favoured the cause of Cicero, endeavoured to possess the place of assembly with armed men, but it had been preoccupied by Clodius. An encounter followed, in which Clodius was victorious, and followed up his advantage by massacring a considerable number of persons. Milo undertook to prosecute him for these outrages, but it was useless to proceed in the regular manner against a man who employed bodies of gladiators in his defence. Milo accordingly provided himself in a similar way, and the two parties had frequent engagements in the streets of Rome. When Cicero was recalled from exile, a question was raised, whether the ground on which his house had stood, and his property, which had been alienated to religious uses, should be restored to him or not. Clodius made a vehement speech against the restoration; but the point being decided in Cicero's favour, enraged Clodius beyond all bounds, and he made an attempt on Cicero's life. He contrived to screen himself from another trial, which he apprehended, by getting himself elected ædile; and no sooner was Milo's tribuneship expired, than he took advantage of the circumstance to prosecute him for acts of violence. Cicero appeared in defence of Milo, who was acquitted. In B. C. 52, Clodius was a candidate for the prætorship. Shortly after, Milo, in his way from Rome to Lanuvium, a distance of about fifteen miles, met Clodius returning from his country seat at Aricia. The meeting appears to have been accidental; but, through the officiousness of a gladiator in Milo's retinue, a fray ensued, in which Clodius received a severe wound. He was carried into an inn at Bovillæ, to be attended to; but Milo, wishing his men to make the most of their victory, Clodius was dragged out of the inn, and killed in the high-road. (Appian, *De Bell.Civ.* ii. 439.) Milo was tried for the murder, and Cicero spoke, though ineffectually, in his defence. Milo withdrew before his condemnation, and retired into exile at Massilia (Marseilles). (Cicero, *Ep. ad Atticum, Pro Milone, Pro Domo Sua;* Plutarch, *Life of Cicero.*)

---

* The Roman palm is equal to 8·79 inches.

CLOGHER, a bishop's see in the archdiocese of Armagh in Ireland. This diocese embraces the greater part of the county of Fermanagh, and the whole of Monaghan, and extends into portions of Donegal, Tyrone, and Louth; its length is 76 miles from N.W. to S.E.; breadth 25 miles from N. to S. It contains 45 parishes, constituting an equal number of benefices, being the only diocese in Ireland in which these divisions coincide. The chapter consists of dean, precentor, chancellor, archdeacon, and five prebendaries. In 1792 there were in this diocese 49 churches of the Establishment. In 1834 the numbers were—churches of the Establishment, 61; Roman Catholic ditto, 81; Presbyterian houses of worship, 32; and other places of Protestant and dissenting worship, 35. In the same year the gross population of the diocese was 399,249; of whom there were 104,359 members of the Established Church; 260,241 Roman Catholics; 34,623 Presbyterians; and 26 Protestant dissenters of other denominations; being in the proportion of 4 Potestants of all denominations to 7½ Roman Catholics nearly. There were at the same time in the diocese 594 daily schools, educating 39,102 young persons, being in the proportion of $9\frac{72}{100}$ per cent. of the entire population under daily instruction, in which respect Clogher stands sixth among the 32 dioceses of Ireland. Of these schools 72 were in connection with the National Board of Education, being in the proportion of 1 to 8¼.

Clogher, from which the bishopric takes its name, is a small town in the barony of Clogher, in the county of Tyrone, so called, it is said, from a golden stone (*Cloch oir*) formerly consulted here for oracular answers by the Druids. It is situated on the Launy, a feeder of the Blackwater, and formerly returned two members to the Irish parliament. The cathedral is the parish church. The bishop's palace, a handsome edifice, with an extensive park, is adjoining.

Saint Patrick is said to have been the first bishop of Clogher, where Jocelyn reports that he founded a see before the erection of the church of Armagh in A. D. 444. Maccartin, the disciple of Patrick, built a cell and monastery here before his death in 506. Prior to this time, Clogher had been the seat of the petty princes of Errigal, a territory which now gives its name to a neighbouring parish. The church was rebuilt A. D. 1041, and again in 1295, by bishop Mathew Mac-Cathasaidh, who enriched it with bells, and various valuables; and again, a century after, by bishop Arthur Mac-Camæil, the former building having been destroyed by fire, together with the cell of Maccartin, the Monastery of the Virgin, two chapels, and thirty-two otner houses, including the episcopal court. The first Protestant advanced to this see was Miles Magragh, in 1570: he was afterwards archbishop of Cashel, to which he was translated in the same year, in consequence of the impoverished state of Clogher about this time. The see was afterwards greatly enriched by a grant of the revenues of the abbey of Clogher, annexed to this bishopric by king James I., in whose reign its revenues were returned at the large sum in those days of 700*l.* per annum. Among the names of the more recent bishops of Clogher are those of Spottiswood, Lesly, Boyle, and Doctor Sterne, the munificent founder of the University Printing-house in Dublin.

By the 3rd and 4th Will. IV., c. 37, Clogher, as soon as vacant, becomes united with the archdiocese of Armagh. (Ware's *Bishops;* Beaufort's *Memoir of a Map of Ireland; Reports of Commissioners.*)

CLOGHNAKILTY, a borough town in the barony of East Carberry and county of Cork, in Ireland; situated on a channel about a mile from the harbour of Cloghnakilty, but without navigation for vessels of more than thirty tons. The charter of the corporation, bearing date 5th May, 11th James I., (1613) was procured by Sir Richard Boyle, the first patron of the borough, and in great measure the founder of the town. By the constitution of the corporation, the power to nominate to all offices was vested in the patron, whose representative, the earl of Shannon, accordingly received 15,000*l.* at the union, as compensation for the loss of the franchise, by which the borough had formerly returned two members to the Irish parliament. The principal part of the present town has been built since the year 1790, about which time a rapid improvement took place in trade of all kinds. Previous to this, most articles of consumption were purchased by retail from Cork or Bandon; but the erection of quays and extensive stores, towards the latter end of the last century, created an independent market, and made this part the point of export of heavy goods for the surrounding country. About the same time it became the most frequented linen and yarn market in that district. The manufacture of linen was also carried on to a considerable extent, as well as the brewing business. Like Bandon, in the same district, the town is now declining both in trade and population. Where 600 persons formerly had employment not more than 150 are now at work. The only trade now carried on is a small manufacture of cotton and export of corn.

The sovereign is the nominee of the patron. The recorder and seneschal, the latter with a court having jurisdiction to the amount of 10*l.* Irish, are nominated by him also. The sovereign's court of record is discontinued; but there are petty sessions held here by the county justices, sovereign, and recorder.

The public buildings are, a church, a Roman Catholic chapel, a barrack, a court-house, and a county bridewell. The chapel, erected by subscription, is a handsome building. In 1815 the number of houses was estimated by the Rev. Mr. Townsend at 586, and of inhabitants at 4688. In 1821 the numbers were;—houses inhabited, 640; inhabitants, 4033; which, in 1831, had decreased to, houses 581, inhabitants 3807. In 1834 there were in the parish of Kilgariff, in which Cloghnakilty is situated, 14 schools, educating 823 young persons. Of these schools two were in connection with the Board of National Education. (*Reports of Commissioners; Stat. Surv. of Co. Cork.*)

CLOISTER, from the Anglo-Saxon clauꞅꞇꞃ or cluꞅꞇeꞃ, adopted from the Latin *claustrum*, a place inclosed or shut up. The term is more particularly applied to the covered walk or inclosure which was the usual appendage of our antient monasteries, where the religious met to converse and take exercise. In a more general sense, cloister is used for a monastery at large, whether of monks or nuns, the inmates being inclosed or shut up from the world. The German word 'Kloster' retains this original signification.

CLONFERT, a bishop's see in the archdiocese of Tuam, in Ireland. The diocese occupies the S.E. portion of the county of Galway, and extends partially into the borders of Roscommon and King's County, stretching east to west about 30 miles, and north to south about 25 miles. It contains 38 parishes, constituting eleven benefices. The chapter consists of a dean, archdeacon, treasurer, and nine prebendaries. In 1792 there were in Clonfert 10 churches of the Establishment. In 1834 the numbers were—churches of the Establishment, 12; Roman Catholic ditto, 44; and other places of Protestant and dissenting worship, 5. In the latter year, the gross population of this diocese was 123,848, of whom there were 4,761 members of the Established Church; 119,082 Roman Catholics; 2 Presbyterians, and 3 other Protestant dissenters; being in the proportion of one Protestant of whatever denomination, to 25 Roman Catholics nearly. There were at the same time in the diocese 111 schools, educating 8,656 young persons, being in the proportion of $6\frac{99}{100}$, or very nearly 7 per cent of the entire population under daily instruction, in which respect Clonfert stands twenty-second among the thirty-two dioceses of Ireland, and is on a par with the diocese of Ross. Of these schools, 7 are in connection with the Board of National Education, being in the proportion of one to sixteen.

Clonfert, from which the diocese takes its name, is a vicarage in the barony of Longford, and county of Galway. The name of the place signifies a wonderful den, or place of retirement. It stands on an isolated height surrounded by bogs, midway between Shannon Bridge and Eyrecourt. There is no town nor village of any consequence. The ruins of the old cathedral are still standing. The episcopal house was built in 1640 by Bishop Dawson.

An abbey was founded here by St. Brendan, the fellow-student of St. Brendan of Birr, A. D. 558. In his time, the cathedral, which was formerly famous for its seven altars, was first founded. Monenius, who died 571, during the lifetime of Brendan, was the first bishop. He was celebrated for his piety, and in 1161 his remains were here deposited in a separate shrine. Roland Lynch, who succeeded to this see in 1602, was also bishop of Kilmacduagh, a neighbouring diocese, which has ever since been held in commendam with Clonfert. By the 3rd and 4th of Will. IV., cap. 37, § 121, the united bishopric of Clonfert and Kilmacduagh, as soon as vacant, is to merge into the joint see of Killaloe and Kilfenora.

(Ware's *Bishops*; Beaufort's *Memoir of a Map of Ireland*; *Reports of Commissioners*.)

CLONMEL, the assize town of the county of Tipperary, in Ireland; situated chiefly on the north side of the river Suir, in the barony of Iffa and Offa East, in the county of Tipperary, and partly on Moore and Long Islands in the same river, in the barony of Upperthird and county of Waterford; 108 miles from Dublin; 52° 19′ N. lat., and 7° 43 W. long. The limits fixed by the Boundary Act include only 361 statute acres, comprising the town on the north side of the river with the islands. A population of about 1000 are excluded by the new boundary line, which cuts off many mean cabins in the suburbs.

Clonmel is a place of considerable antiquity. It is said to have been walled by the Danes. Otho de Grandison, who had a grant of Tipperary, and a considerable portion of Cork, was the first English possessor. He founded a Franciscan Friary here, A. D. 1269.

Clonmel, from its situation on the frontiers of the pale, was a convenient station for assembling on any emergency. The town appears to have continued faithful to the crown until the rebellion in favour of Simnel and Warbeck. A disposition to revolt was also manifested by the inhabitants on the death of Queen Elizabeth. On the breaking out of the war in 1641, Clonmel declared for the Roman Catholic cause. Clonmel continued a strong hold of the ultra Roman Catholic interest until the end of the war, and made a good defence against Cromwell, who besieged, and finally took it in 1650. Clonmel was now dismantled, but continued to adhere to the losing party until after the conclusion of the wars of the revolution by the treaty of Limerick. Few antiquities remain: a gate-house at one end of the main street is the only part of the old works standing.

The town is governed under charter of the 5th July, 6th James I. The corporation consists of the mayor, five burgesses, and commonalty; and is one of those subject to the regulation of the 'new rules' of the 25th Charles II. The patronage is in the family of Bagwell. Prior to the passing of the Reform Act, the same family had also the return of the member for the borough. The assizes for the county of Tipperary are held here twice a year; petty sessions for the same county, which do not take cognizance of any matters arising in the town or liberties, are held once a fortnight. The mayor's weekly court has jurisdiction to the amount of 10*l*. Irish. The court, in which the mayor also presides, has unlimited jurisdiction in civil, but none in criminal matters. This court has fallen into disuse from the heavy stamp duty on the admission of attorneys to practise in it. There is no corporation gaol, but a county gaol, house of correction, and marshalsea. The corporation has no criminal jurisdiction. The property of the corporation has been mismanaged. Their estate, of 4800 Irish acres, produces only 416*l*. 13*s*. 11½*d*. per annum Many of the leases under which it is at present held have been executed lately, some of them to the patron, at an under value. There are twelve monthly fairs, ten of them the exclusive property of the patron; and markets twice a week. (*Report of Commissioners on Municipal Corporations in Ireland*.)

The present condition and appearance of the town are highly respectable. Southward from the main street, which runs parallel with the river, diverge three streets, leading to as many bridges, two of which are carried over the islands in the Suir. Adjacent to the lowest bridge are the works which supply the town with gas: a house of instruction stands near the upper. There are barracks for a regiment of foot and two troops of horse, a fever hospital, a parish church built in the form of a cross, a Roman Catholic chapel, and a large cotton manufactory. The market-house is strong and well built. The lunatic asylum for the county of Tipperary, opened here in 1833, cost 16,587*l*. 19*s*. 3*d*., and is calculated for sixty patients. The cost is to be defrayed by fourteen annual instalments by the county. Commissioners, appointed 25th Sept., 1828, under 9 Geo. IV., c. 82, regulate the lighting and watching of the town: for the last seven years gas has been employed. The amount of watching and lighting tax, levied annually, is 753*l*. 14*s*. 8*d*. The streets are paved and cleansed by the corporation. The expense of paving and cleansing for 1833 amounted to 417*l*. 4*s*. 0*d*. For the last fifteen or sixteen years Clonmel has been steadily advancing in prosperity. 'It is,' says Mr. Inglis, 'the great point of export for Tipperary, which is one great granary, as well as for parts of other counties, for it is the first point at which water-carriage commences.' The exports are chiefly corn, bacon, and butter; of the first article from two to three hundred thousand barrels of wheat are annually brought into the town. The flour mills are very numerous and extensive. The family of Grubb, and other members of the Society of Friends, have been chiefly instrumental in bringing the milling trade to its present importance in this district. The bacon trade is also very extensive; 50,000 pigs per season is the average. The butter trade, though large, has lately been somewhat on the decline. Another considerable source of employment is the great posting establishment of Mr. Biancoui, of which Clonmel is the depôt. There are also several breweries, and an extensive distillery in the vicinity; and a large cotton manufactory, which occupies about 200 persons. There is consequently little want of employment; and the town, up to 1821, rapidly increased. Since 1821 the population has been nearly stationary. There are great facilities for building. Limestone, sand, and good quarries are abundant in the immediate vicinity of the town. An improvement of the navigation of the Suir is very desirable.

The borough, as laid down in the Boundary Report for 1831-2, contains 1532 houses; of which 419 are thatched, and 1113 are slated, and 771 have seven windows and upwards; with a population of 12,256, and a probable constituency of 652. The population of the whole town, in 1821, was 1590, consisting of 7272 males and 8318 females: in 1831 the numbers were respectively 6654 and 8480. In 1821 the number of inhabited houses was 2035, and of families 3847: and in 1831 the numbers were respectively 1793 and 2734.

The population of the entire parish of St. Mary, in which Clonmel is situated, was, in 1834, according to the first Report of the commissioners of public instruction, 17,853; of whom there were 1737 members of the Established Church, 15,848 Roman Catholics, 44 Presbyterians, and 206 other Protestant Dissenters. According to the second Report of the same commissioners there were in the same parish, in 1834, 25 daily schools, educating 830 males and 246 females; total, 1172. Of these schools there are two endowed. One is a boarding and day school. The endowment, amounting to 400*l*. Irish annually, is by the families of Mountcashel and Ormond: the other is a parochial school, with a small endowment of 7*l*. Irish per annum. There does not appear to be any free school, except one for ten females, nor are any of the above in connection with the Board of National Education.

(Cox's *History of Ireland*; Carthehaven's *Memoirs*; Inglis's *Ireland in* 1834; *Post Chaise Companion*; *Pub-*

lications of the Irish Record Commissioners; Parliamentary Reports and Papers.)

There is no local history of Clonmel, nor is there any history of the county of Tipperary.

CLONMINES, a decayed borough, situated on a creek in the barony of Shelburne and county of Wexford, in Ireland. It formerly returned two members to the Irish parliament, for the loss of which franchise the earl of Ely and Charles Tottenham, Esq., received 15,000*l.* compensation at the Union. There are now no remains whatever of a town or corporation. (*Reports of Commissioners.*)

CLORO'DIUS. [Crab.]

CLOSTERI'NUM. [Phytozoaria.]

CLOTAIRE I., the youngest son of Clovis, the conqueror of the Gauls, and of his wife Clotilda. Clovis having divided his territories at his death, A.D. 511, among his four sons, Clotaire became king of Soissons. He joined his brothers in their war against the Burgundians, which ended in the defeat of the Burgundians, and the extinction of the first kingdom of Burgundy, which was divided among the brother kings of the Franks. Clotaire and his brother Childebert, king of Paris, invaded the kingdom of Orleans after the death of their brother Chlodomère, and murdered two of his sons. The third, named Chlodovalde, concealed himself in an hermitage near Paris, where the village of St. Cloud has since risen. After the death of his nephew Theodebert, king of Austrasia, Clotaire took possession of that kingdom also; and after the death of Childebert, Clotaire united in his person the whole monarchy of the Franks, A.D. 558. His natural son, Chranme, having revolted against him, joined the count of Britanny, who maintained his independence against the kings of the Franks. Clotaire defeated his son, and burnt him alive with his family in a hut in which he had taken shelter, A.D. 560. In 562 Clotaire died, and was buried in the church of St. Medard of Soissons. He left four sons, among whom, following the example of his father, he divided the monarchy of the Franks. Caribert was made king of Paris, Gontran king of Orleans and Burgundy, Siegbert king of Metz or Austrasia, and Chilperic king of Soissons.

CLOTAIRE II. was the son of Chilperic, king of Soissons, or of Neustria, and of his wife Fredegonda. His father died, and left him an infant, under the regency of his mother. After many cruel wars, occasioned by the rivalships between Fredegonda and Brunehaut, the wife of Siegbert, king of Austrasia, Clotaire united in his person the whole empire of the Franks, as his grandfather Clotaire I. had done before him, A.D. 613. Having taken Brunehaut prisoner, he put her to a cruel death. Clotaire, in order to conciliate his new subjects of the kingdoms of Burgundy and Austrasia, appointed a Maire du Palais, Major Domus Regiæ, to each, for life. The office previously seems to have been held, as well as in Neustria, during pleasure only. The Maires of Austrasia, in the following reigns, became by degrees independent of the sovereign, and at last usurped the supreme power. At the council of Paris, A.D. 615, Clotaire issued general ordinances, which were called 'Capitularia.' He also convoked at times a kind of temporary parliament (so called from the word *parlié*, or *parler*, 'to speak'), which was an assembly of the chief officers of the Franks. The bishops had not admission into these assemblies till the time of Pepin, the father of Charlemagne. (*Histoire du Parlement de Paris.*) These parliaments were also called 'Placita,' from which term are derived the words *plaids* and *plaider*, 'to plead.' Clotaire had to sustain a war in his German dominions beyond the Rhine against the Saxons, whom he defeated with the loss of their king, A.D. 626. In 628 Clotaire died, aged forty-five years, and was buried at Paris in the church of St. Germain des Prez. His son Dagobert, who succeeded him, gave to his brother Caribert part of Aquitania with Toulouse for his residence. Clotaire II. was a man of abilities and of considerable information for his time: he was brave and popular, but ambitious, unprincipled, and cruel, like most of the Merovingian kings. (Velly, *Histoire de France sous la Première Dynastie.*)

CLOTHO, a genus of fossil bivalve shells, established by Faujas de Saint Fond for a species found in the shells of Cypricardiæ. *Shell* oval, subregular, striated longitudinally, equivalve, subequilateral. *Hinge* formed by a bifid tooth, curved into a hook, a little larger in one valve than in the other. *Ligament* external.

CLOTILDE, MARGUERITE ELEONORE, born at Vallon Chalis, in the Vivarais, on the banks of the Ardèche, about 1405, married Bérenger de Surville, who soon joined the army of the dauphin, afterwards Charles VII., and was killed at the siege of Orléans. During his absence Clotilde is said to have composed and addressed to him her first epistle, which she called 'Héroide,' in imitation of Ovid's compositions of the same name. She afterwards, during her long widowhood, is said to have composed the other poems which bear her name. They consist chiefly of ballads, rondeaux, chansons, epistles, with fragments of an epic poem. The last in date is a chant royal, on the occasion of the battle of Fornovo gained by Charles VIII. But the authenticity of these compositions is very much doubted. It rests merely on the reported assertion of Joseph Etienne de Surville, a descendant of Bérenger, and an officer in the royal army, who emigrated at the time of the French revolution, but who having re-entered France in 1798 was tried and executed. He is said to have discovered Clotilde's autograph MSS. among the family papers, which however were all destroyed at the time when the peasantry went about burning the mansions of the nobility. He entrusted some friends with a copy of the poems, which were first published by Vanderbourg in 1803, with a biography of Clotilde. For the controversy about their authenticity, see *Biographie Universelle*, art. 'Surville' (Clotilde), and the authorities referred to; among others, Raynouard's article in the *Journal des Savans*, July, 1824. The poems are not without merit; and if not written by Clotilde they are a very clever imitation of the old French style of the fifteenth century, although some of the images and expressions appear to betray a later origin. Clotilde is said to have died at a very advanced age. (Biography, prefaced to Vanderbourg's edition).

CLOUD, a mass of vapour or other substance not a necessary constituent of the atmosphere, elevated to a considerable height in it. When very near the surface of the earth, it takes the name of mist; or rather, perhaps we should say, it is presumed as a probable hypothesis that the substances called cloud and mist differ only in position.

Our knowledge of cloud, as long as it is *cloud*, must necessarily be small, though the consideration of the phenomena connected with the appearance and disappearance of clouds, their formation and consequences, is an important, and we may now say an extensive, branch of Meteorology. Writers on this last-named subject do not treat much of clouds, except in connexion with other phenomena, rain, thunder, &c., and we may therefore refer to other articles for the most important facts.

In its permanent state, a cloud is conjectured to be a mass of *vesicular vapour*, that is to say, a collection of minute watery globules filled with air. A mass of vapour, in the strict sense of the term, could not be maintained *in equilibrio* when isolated in the air in the manner of a cloud. But even the preceding explanation is not without its difficulties. The globules (if full of air) must be specifically heavier than air, and it is not easy to see how they can maintain their position. The ascent of currents of heated air, and the retention of solar heat, have been suggested: but we shall content ourselves with the remark of M. Pouillet, that our *data* on this subject are too few to render any attempt at explanation advisable; and that we have nothing but more or less probable conjectures as to the causes which determine the form, the extent, the elevation, colour, &c., of these masses.

The motion of the clouds, though frequently depending on that of the wind, and sometimes proving the existence of a counter-current in the higher regions of the atmosphere, is nevertheless often caused by an action of one mass upon another, which there is every reason to attribute to the difference of their electrical states. Here we have again a branch of meteorology which is yet only beginning. The conjectures relative to weather, formed by observation of the state of clouds, will require a long course of observation before the truth can be separated from fiction. That many persons who are in the habit of observing, and seamen in particular, do acquire a sort of power of prediction which frequently is correct, cannot be denied; but if we except perhaps the general fact, in which all the world is agreed, namely, that collection of clouds promises rain and dispersion fair weather, there are no rules in which even continual observers are agreed.

The height of the clouds varies to upwards of a mile, being much more frequently less than more. Mr. Dalton however asserts that small fleecy patches of cloud are frequently from three to five miles in height. The average height varies at different periods of the year. The following observation (and if the subject had been often studied in this way, we could perhaps have written more definitely upon it) is given by Mr. Dalton in the first edition of his Meteorological Essays (1793), the observer being Mr. Crosthwaite of Keswick. By accurate measurement of Skiddaw, and fixing marks on the side of the mountain, which is 1050 yards high, he was able to ascertain by inspection the height of any cloud, when it did not exceed that of the mountain.

This he did three times each day, morning, noon, and evening, for five years, missing only as many observations as amounted to omitting less than a week per year. The result is as follows, the last column giving the number of times in which either the clouds were above the mountain, or there were no clouds at all, the last circumstance occurring about once out of thirty times.

Thus, it appears, that in the month of September, for instance, for seven times that the clouds were between 200 and 300 yards high, there were 38 times in which they were between 500 and 600 yards high, &c. The supposition of the height of the clouds depending on the barometer, was in no degree countenanced by these observations, and though in heavy and continued rains the clouds were mostly below the summit, yet it frequently rained when they were above it.

The most complete classification of clouds, and sketch of their usual forms and arrangements, is to be found in a paper by Mr. Luke Howard, first published in Tilloch's Magazine, then in Rees's Cyclopædia, afterwards in Nicholson's 'Journal of Natural Philosophy,' &c., vol. xxx. p. 35. In this paper Mr. Howard first proposed the nomenclature which is now so frequently used, and of which we give the heads in his own words.

1. *Cirrus*. A cloud resembling a lock of hair, or a feather. Parallel, flexuous, or diverging fibres, unlimited in the direction of their increase.

2. *Cumulus*. A cloud which increases from above in dense, convex, or conical heaps.

3. *Stratus*. An extended continuous level sheet of cloud, increasing from beneath.

4. *Cirro-cumulus*. A connected system of small roundish clouds, placed in close order or contact.

5. *Cirro-stratus*. A horizontal or slightly inclined sheet, attenuated at its circumference, concave downward, or undulated. Groups or patches having these characters.

6. *Cumulo-stratus*. A cloud in which the structure of the cumulus is mixed with that of the cirro-stratus, or cirro-cumulus. The cumulus flattened at too, and overhanging its base.

7. *Nimbus*. A dense cloud spreading out into a crown of cirrus, and passing beneath into a shower.

CLOUD, ST., a small town in the immediate neighbourhood west of Paris. It lies on the left bank of the Seine, not far from Sèvres; the road to it is a branch from the great road by Sèvres to Versailles. It is in the department of Seine et Oise.

This place is said to have been known, in the earlier ages of the Frankish monarchy, by the name of Nogent. Chlodovalde, one of the three sons of Chlodomère, king of Orléans, retired hither in the sixth century, having embraced a monastic life to avoid the fury of his uncles Childebert and Chlothachaire or Clotaire, who had (A.D. 533) murdered his two brothers in order to seize their inheritance. This prince was canonized, and his name, corrupted into St. Cloud, has been given to the town where he passed his life and where he was buried.

The claims of this place to notice are founded upon its park and palace, the favourite residence of Napoleon, and now the usual summer residence of the king of the French. Within the limits of this park was formerly a château belonging to a Florentine, Jerome de Gondi, in which Henry III. of France took up his quarters during the siege of Paris by his own forces and those of Henry IV., the king of Navarre. Here he was killed, A.D. 1589, by the monk Jacques or James Clément. The heart of the unfortunate prince was deposited in the parish church of St. Cloud, with this inscription, 'Passenger, pity the lot of kings!' The church, which had long been in a decayed condition, was demolished a little before the revolution by the queen Marie Antoinette, who commenced the erection of a new one at her own cost; but the breaking out of the revolution put a stop to it. The domain with an adjacent one was purchased by Louis XIV., and given to his brother the duke of Orléans. The present palace, built by the duke, has engaged the talents of several architects, among whom is Mansard. It was purchased a little before the revolution by Marie Antoinette, who much enlarged it, and rendered it more magnificent. Bonaparte, on his return from Egypt (A.D. 1799), assembled the Council of the Five Hundred in the palace of St. Cloud, and dissolved them by force.

The park of St. Cloud extends from Sèvres to the town of St. Cloud, on a hill which rises above the bank of the Seine. The lower part of the park, along the bank of the river (from which it is separated by a road and towing path), is occupied by a magnificent plantation of elms and by green lawns: it is the part most frequented by those on foot, as being the nearest to Paris, and the most commodious for walking. But the upper part of the park, and the wooded slope of the hill on which it lies, excel the lower part in picturesque beauty. The slope, skilfully planted, is adorned by masses of foliage, by frequent steep declivities, and by pleasant recesses. Down this slope falls the cascade of St. Cloud, the water tumbling from one basin to another carved in the form of shells, and adorned with grotto-work, statues of marble and figures cast in lead; at the bottom of the cascade, the 'giant jet' spouts up a column of water to the height of more than a hundred feet. The upper part of the park has spacious lawns and alleys of trees stretching beyond the reach of the eye, but the turf is not so fresh nor are the trees so vigorous as in the lower part. At the edge of the slope, a platform called 'La Balustrade' commands an extensive view, including the long meanderings of the Seine, the whole extent of the capital, and a considerable part of the surrounding country. From this platform rises a lofty square tower, from the top of which is a prospect still more extensive. This tower was built by Bonaparte A.D. 1801, and on the top of it is a copy of the lantern of Demosthenes.

The château of St. Cloud is equally admired for the beauty of its situation and the elegance of its architecture. It has not indeed the vast magnificence of Versailles, but it is as beautiful with less pretension. It consists of a principal front and two wings at right angles, inclosing three sides of a square, the fourth side of which is formed by a terrace and balustrade, from which there is a view of the park and of the same objects which the platform commands. There are three porticos of the Corinthian order, one in the centre of the principal front, and one at the extremity of each wing; the intervals are adorned with statues and reliefs. The most remarkable parts of the interior are the gallery painted by Mignard, and the room called the 'Salon de Mars,' the ceiling of which was painted by the same artist; but the chief ornament of it is four superb marble columns. The pictures are not numerous, but they are well chosen. The château was much improved and splendidly furnished by Napoleon.

The town of St. Cloud abounds with houses of public entertainment, tea gardens, cafés, &c. The population in 1832 was 1935. There is an annual fair in September, which lasts three weeks, and attracts a number of persons from Paris on the Sundays which fall during its continuance. (Vaysse de Villiers.)

CLOUDBERRY, a dwarf kind of bramble, with herbaceous stems, and orange-yellow fruit, found in turfy alpine bogs: it is the *Rubus chamæmorus* of botanists. Its fruit is excellently well flavoured when newly gathered.

CLOVE PINK, a species of Dianthus, so called from a supposed resemblance in odour between its flowers and the cloves of the shops.

CLOVER, a name given to different species of Trifolium. Dutch clover is T. repens; purple clover is T. pratense; cowgrass, or perennial clover is T. medium.

Clover was introduced into the agriculture of Great Britain about the sixteenth century, from the Low Countries, where it had been long cultivated as green food for cattle in situations where natural pastures were scarce. It was the first step towards the improvement of the old triennial system. Its abundant produce, its destruction of annual weeds, which it smothers by its broad foliage, and especially the beauty of the wheat sown after it, soon recommended it as an indispensable part of an improved rotation of crops. It is not too much to say, that the profit of any farm may be considered as proportionate to the quantity of clover which is produced upon it on an average of years. There are various kinds of clover, which all go under the botanical name of trifŏlium, from the three leaves which grow together, or rather the form of the leaf, which has three heart-shaped parts. They are annual, biennial, or perennial plants. The annual clovers, with the exception of the trifolium incarnatum (*Trèfle incarnat* or *farouche*), introduced from the south of France, are not so generally cultivated as the biennial, which produces a greater crop, and being sown along with the spring corn comes up the first year under its shade, and gives a full crop in the second. In good land it will sometimes stand another year, but it falls off in quantity; and unless other artificial grasses or perennial clovers have been sown amongst it, to fill up the places where the biennial clover has failed, it is seldom profitable to allow it to remain on the ground more than one year after that in which it is sown.

The most approved variety of the biennial clovers is the common red or broad clover (*Trifolium pratense*), which is usually sown with barley or oats, or sometimes among wheat or rye in spring. When these are drilled and hoed there is an advantage in sowing the clover seed among a crop which is already advanced in growth, because it is kept under, and there is no danger of its injuring the chief crop by its too great luxuriance. There is however some risk of the clover not coming up so well, if the wheat or rye is very close on the ground. In Scotland clover is often sown among wheat, in Norfolk invariably with barley, and in Belgium among rye. This depends on the various rotations adopted in different countries. The first crop is generally mown and made into hay. In this process great care is taken not to break off the tender leaves of the plant in drying; the swarth is not shaken out as is done with meadow grass, but merely turned over; and if the clover can be dried and put in a stack without any shaking, it is so much the more valuable. When clover is soaked with rain, no hope of an improvement in the stack must induce the farmer to carry it together, so long as the least moisture remains. If it is allowed to stay in the field till it is perfectly dry, even when it has been soaked repeatedly and is nearly black, and is then trod hard in a rick with a sprinkling of salt over each layer, it will be readily eaten by cattle in winter, and be far more nutritious than that which, having been stacked in a moist state, will infallibly come out musty. A very good method in those seasons when a continuance of dry weather cannot be reckoned upon—particularly when the second crop is cut in September—is to take advantage of two or three dry days to cut the clover, and turn it as soon as the dew is completely dried off the upper side; the next day do the same, and in the evening carry the green dry clover and lay it in alternate layers with sweet straw, so as to form a moderately sized stack. A fermentation will soon arise, but the dry straw will prevent all danger from too much heating, and, acquiring the flavour of the clover, will be eaten with avidity by the cattle. To those who make clover-hay for the use of their own stock in winter, we recommend this as preferable to the common method, even when there is less danger from the weather. In northern climates it would probably save the crop two years out of three.

It is usual to sow rye-grass (*Lolium perenne*) in a small proportion with clover seed, especially where clover, having been often repeated on the same land, is apt to fail. It is a good practice; and although in the neighbourhood of London the unmixed clover obtains a better price, there is no reason why it should be preferred, unless the rye-grass has been allowed to stand too long and has grown hard. Young rye-grass is a good corrective of the heating qualities of clover-hay. A very extensive use of clover-hay in London is to cut it into chaff, and to mix this with oats and beans for dray horses, which have little or no hay given them in any other way; but the most profitable use of clover is to cut it green for horses and cattle. With a little management and the assistance of tares, green food may be given to all the stock from the first day of May to the end of November.

The land which has borne clover, although in a very good state for producing corn, will not bear a repetition of that crop until several other crops have intervened. In the regular Norfolk rotation, clover should recur every fourth year; but after a few rotations this is found to be too quick a recurrence, and other grass seeds or pulse are substituted. The Flemish do not sow clover again on the same ground sooner than in eight or ten years.

The white or Dutch clover (*Trifolium repens*) is a perennial, which grows rapidly, and forms excellent pasture; but its bulk is not sufficient to make it profitable to mow it for hay. It is excellent for sheep, which thrive well upon it. A light calcareous soil is best adapted for white clover; but it also grows well on heavy land, provided the bottom be sound and dry. When land is laid down for permanent pasture, white clover is always sown in a considerable proportion with other grasses.

Another perennial clover, called cow grass (*Trifolium medium*), is found in all rich meadows: it is often sown in conjunction with the white clover in laying down arable land to grass. The lesser yellow trefoil (*Trifolium minus*) and the hop trefoil (*Trifolium procumbens*) are also valuable varieties found in good pastures.

The only annual clover which is cultivated is the French clover (*Trifolium incarnatum*), mentioned before. It is a most valuable addition to the plants usually sown for fodder, from the short time in which it arrives at perfection if sown in spring; so that where clover has failed, this may be sown to fill up the bare places. Its principal use is to raise very early food for ewes and lambs, which it does with very little trouble or expense. Immediately after harvest the stubble is scarified and harrowed so as to raise a mould; the Trifolium is sown at the rate of 16 to 20 lbs. per acre, and well rolled in. It springs up and stands the winter well, and with the first genial weather in spring it grows rapidly. It makes excellent hay, and what is left produces seed most abundantly in the end of May or beginning of June, being off the ground in good time to plough the land and clean it for turnips. It is far superior to stubble turnips as an intervening crop, and more rapid in its growth than tares. On light land a crop of buckwheat is readily obtained after it. It has the property of smothering annual weeds by its rapid growth, and for this reason is not so well adapted for sowing with a crop of corn. The Italian rye-grass (*Lolium perenne Italicum*) may be sown with it, and will grow as rapidly. After the Trifolium has been cut, this will continue and give an excellent second crop. It is advisable to have fresh seeds from southern climates from time to time, or it will probably become later every year by assimilation to the climate. English seed of the first year after importation seems the best, being heavier and more free from weeds than the foreign.

Some agriculturists have objected to the practice of sowing clover with a crop of corn; they prefer hoeing the intervals between the rows of the drilled crops, by which the weeds are better kept down. They plough the land immediately after harvest, and harrowing it well, they sow clover and grass seeds, which come in nearly as soon the next year as if they had been sown in the preceding spring; and the land, when broken up, is in a much cleaner state than if the clover had been sown with the corn. If this be not an improvement in the system, it is at least worthy of notice, and experience alone can decide whether the additional expense of ploughing is repaid by the improvement in the crop.

In France and in the United States of North America gypsum is considered as a specific manure for clover. It is sown by hand over the plant in spring, and in some situations the advantage is evident, in others scarcely observable. The quantity used is from three to eight bushels of finely powdered gypsum per acre.

On good land an acre of clover will produce as much as three tons and a half of dry hay; that is, two tons the first cutting, and one and a half the second. Greater crops are obtained on very highly manured land. The value of a ton of clover-hay to feed horses with is about 15 or 20 per cent. more than good meadow-hay. It is not however so good for milch cows. The price in London is from 4*l.* to 5*l.* per ton on an average.

When clover is intended to be left to ripen its seeds, it should be mown early, or fed off by sheep in May. The first crop is seldom free from various seeds of other plants which rise among the clover: by feeding it down or mowing it these are destroyed, and the clover, which grows more rapidly than most other plants, rises again without any mixture of weeds. When the blossom is thoroughly withered, and the seed is nearly ripe, the clover is mown and left to dry on the ground without much shaking. In very dry weather it may be housed or stacked in a week; but the process is much retarded by showers and want of sunshine. It is therefore only in the drier parts of the island that clover seed repays the expense and risk of cultivation, especially as it is well known that the subsequent crop suffers if the clover is allowed to stand for seed. It is seldom therefore that more seed is saved, even in the most favourable situations and seasons, than is required for the farm or immediate neighbourhood. The demand from the North, where clover is sown to a great extent, could not be supplied without a considerable importation from abroad: and this has caused an outcry against the duty of 20*s.* per cwt. on foreign seed, as a tax on agriculture. Notwithstanding this high duty, the importation of clover-seed from Belgium and Holland is very considerable, as it is more advantageous to purchase foreign seed than to raise it; except in the case of the *Trifolium incarnatum*, which produces early and abundant seed. Foreign clover-seed should be well examined when it is purchased, as it frequently contains the seeds of docks and other noxious weeds. The usual mode of doing this is very simple. The thumb is moistened and pressed on the sample, some of the seeds adhere, and when it is turned up the quality is distinctly seen by the colour and plumpness of the seeds. If any seeds of weeds are in it, they must be detected after a few insertions of the thumb. As the calyx of the flower of clover envelops the seed closely, it is difficult to separate them. In Holland they have various machines for this purpose, one of which consists of two fine-rodded hurdles made to rub on each other whilst the heads pass between them. In England it is generally threshed on the floor. But if the heads, after being separated from the haulm, are put together in a heap and pressed, a slight fermentation takes place, and this makes the calyx brittle, so that it breaks into dust, and the seed comes out readily; it is then easily cleared by the fan.

When the seed is not intended for the market, the trouble of clearing it of the husk may be saved, especially in the *Trifolium incarnatum*. It will grow as well when sown with the husk as when cleaned; and it is easy to find the proportion required to be sown in that state by allowing for the weight of the husk.

CLOVES, the dried flower buds of Caryophyllus aromaticus.

CLOVIS, CLODOVEUS, and **CHLODWIG** in old German, from whence Ludwig, the Latinized form Ludovicus, and Louis are derived, was born A.D. 467. He was the son of Childeric, and grandson of Merowig, who gave his name to the Merovingian dynasty. Tournay was then the capital of the Salian Franks, who had occupied the north-east part of Gaul, and extended their incursions as far as Paris. After the death of Childeric, A.D. 481, Clovis attacked Siagrius, the Roman commander, defeated him near Soissons, took him prisoner, and beheaded him. Having conquered the whole country, south and west, as far as the Seine, he fixed his residence at Soissons. He afterwards got rid, by force or treachery, of the other Frankish chiefs, his own relatives, who held various parts of North Gaul: Siegbert, king of Cologne, Cararic, king of the Morini, Ranacarius, king of Cambrai, and others, all perished by his hand.

In 493 Clovis married Clotilda, the daughter of Chilperic, king of the Burgundians, who was a Christian. Clovis and most of the Franks were still Pagans. In 496 Clovis fought a great battle at Tolbiac, near Cologne, against the Alemanni, who had advanced to the Rhine and threatened Gaul. In the most critical moment of the fight, it is said that he made a vow to acknowledge the God of Clotilda if he remained conqueror. The Alemanni were completely defeated, and Clovis and most of his soldiers were christened on Christmas day of the same year, by Remi, archbishop of Rheims. The Gauls and Romans of the western provinces, as far as the mouth of the Loire, submitted voluntarily to Clovis.

He next turned his arms against Alaric II., king of the Visigoths, in the south-west part of Gaul, whom he defeated the battle of Vouilli, near Poictiers, A.D. 507; Alaric fell, and Clovis took possession of the whole country as far as the Pyrenees. Theodoric, king of the Goths in Italy, coming to the assistance of his countrymen, defeated Clovis near Arles, 509, after which peace was made between the Goths and the Franks. Anastasius I., emperor of Constantinople, bestowed upon Clovis the titles of Patrician and Augustus, and sent him a crown of gold and a mantle of purple, A.D. 510. Clovis now fixed his residence at Paris. In 511, at the Council of Orleans, the rights called Regalia were acknowledged by the bishops as vested in the kings of the Franks. By these rights, on every vacancy of a See, the revenues devolved on the king, who had the right of nomination. Clovis caused the laws and customs of the Salian Franks to be compiled and arranged to serve as a code for his Frankish subjects. His Gaulish and Roman subjects were subject to the Theodosian Code. In 511 Clovis died at Paris, after a reign of 30 years, and was buried in the Church of St. Peter and Paul, afterwards called Sainte Geneviève. When the old church of Sainte Genevieve was pulled down on May 10, 1807, two sarcophagi of stone were found with the remains of Clovis and his wife Clotilda, as well as an epitaph upon the former, written long after his death. They are preserved in the 'Musée des Monumens Français,' as well as a statue of Clovis, erected to his memory by King Robert, towards the beginning of the 11th century. Clovis left four sons, among whom he divided his monarchy. [CLOTAIRE I.] Clovis first reduced the Franks to the condition of a united and partly civilized nation. His conversion to Christianity conciliated the clergy as well as his Roman and Gaulish subjects, most of whom had embraced that faith.

CLOYNE, a Bishop's see, in the archdiocese of Cashel, in Ireland. The chapter consists of a dean, chanter, chancellor, treasurer, archdeacon, and fourteen prebendaries. The diocese occupies the greater part of the county of Cork, from the river Lee northward, and lies wholly within this county, with the exception of a part of one parish, which is in the county of Waterford. It extends from E. to W. 63 miles, and from N. to S. 29 miles. In 1792 the number of parishes was 137, and of benefices 69, with 51 churches of the Establishment. It now contains 122 parishes, constituting 84 benefices. In 1834 the places of worship were—churches of the Establishment, 64; Roman Catholic ditto, 89; other places of Protestant and Dissenting worship, 30. In the same year the gross population of this diocese was 342,477; of whom there were 13,866 members of the Established Church; 328,402 Roman Catholics; 14 Presbyterians; and 195 other Protestant Dissenters; being in the proportion of one Protestant of whatever denomination to $23\frac{1}{3}$ Roman Catholics nearly. There were at the same time in this diocese 379 daily schools, educating 21,043 young persons; being in the proportion of $6\frac{1}{10}$ per cent. of the entire population under daily instruction, in which respect Cloyne is on a par with Kilfenora, and stands 25th among the 32 dioceses of Ireland. Of these schools, 19 were in connection with the Board of National Education, being in the proportion of 1 to 20 nearly.

Cloyne, from which the bishopric takes its name, is a vicarage and small town in the barony of Imokilly, and county of Cork. The name may signify a place of retirement: by some it is derived from cluaine, a cave, from the number of caves with which the limestone strata of Imokilly abound. The chief object of interest here is a round tower, 92 feet in height, surmounted by a modern battlement, the original conical roof having been destroyed by lightning in 1749. East of the round tower, on the opposite of the street, stands the cathedral, a small heavy building, supposed to have been raised about the end of the thirteenth century. The episcopal palace adjoins the town; it is a plain mansion, built in the early part of the last century by Bishop Crowe, and stands in a handsome demesne. The town itself is an inconsiderable place, consisting of one principal street of mean houses. It was estimated in 1800 to contain 308 houses, and rather more than 1600 inhabitants. The number of inhabitants is now about 2000. Being the only market-town in a considerable extent of country, its fairs are usually well attended. In 1834 there were in Cloyne 8 schools, educating 556 young persons; of these schools there was one endowed, and one a free-school.

The founder of the bishopric was Colman, son of Lenin, the chief bard of Aedh, king of Munster. He died A.D. 604. There are few records of the see prior to the arrival of the English, about which time one Mathew was bishop; he is supposed to have been the same with the then legate of Ireland. About the year 1327 this see had become so impoverished, that king Edward III. wrote to Pope John XXII. for the purpose of uniting it with the diocese of Cork, also at that time much reduced: but the contemplated union did not take place till more than a century after, when, both sees happening to be vacant, they were consolidated by Pope Martin V. in the person of Bishop Jordan, about A. D. 1430.

About the time of the Reformation, this see, in common with almost every other diocese in Ireland, had suffered severely in its temporalities, part being forcibly seized on by lawless neighbours, and part being fraudulently made away with by lay prebends and dishonest bishops, insomuch that, says Harris, 'there was not one bishopric in the province of Cashel that had not the print of the sacrilegious paw upon it; and on some of them *vestigia nulla retrorsum*.' To so low a state was Cloyne reduced at this time, that the bishop of it was called '*Episcopus quinque marcarum*,' five marks being the whole of its annual revenue.

Cork and Cloyne continued united until, in 1638, Doctor George Synge was consecrated Bishop of Cloyne, separately, by Usher, at Drogheda. Bishop Synge dying in 1653, the see was vacant until, on the cessation of the civil wars in 1660, it was bestowed on Michael Boyle, who held it again united with Cork, and also with Ross, as did his next successor, Bishop Edward Synge, since whose death in 1678 these sees have been in separate hands. Bishop Crewe, one of his successors, in 1702 recovered to the see upwards of 8000 Irish acres of land which had been fraudulently conveyed away by some of his predecessors; he was besides a munificent benefactor to the town, in which he founded a free-school, at present enjoying 190*l.* 8*s.* per annum, and educating 35 boys by his bequest.

Among the distinguished prelates of the see are the names of Berkeley, and the late Bishop Brinkeley.

By the 3rd and 4th Wm. IV., c. 37, sec. 121, Cloyne is to be reunited to Cork and Ross as soon as these latter sees become void.

(Ware's *Bishops;* Beaufort's *Memoir of a Map of Ireland; Reports of Commissioners;* Croker's *Sketches in the South of Ireland.*)

CLUB is defined by Johnson to be 'an assembly of good fellows, meeting under certain conditions;' but by Todd, 'an association of persons subjected to particular rules.' It is plain that the latter definition is at least not that of a club as distinguished from any other kind of association, although it may not be more comprehensive than is necessary to take in all the associations that in modern times have assumed the name of clubs. Johnson's however is the more exact account of the true old English club.

It might not be quite safe to make a positive assertion as to the antiquity either of the name or the thing in England. But the earliest clubs remembered in our popular literature date about the end of the sixteenth or the beginning of the seventeenth century. It was then that there was established the famous club at the Mermaid Tavern, in Friday Street, of which Shakspeare, Beaumont, Fletcher, Raleigh, Selden, Donne, &c., were members.

Ben Jonson had another club, of which he appears to have been the founder, that met at another well-known tavern, called the Devil Tavern. It stood between the Temple Gates and Temple Bar. It was for this club that Jonson wrote the 'Leges Convivales,' which are printed among his works.

It seems to have been not till a considerable time after this that political clubs first came into vogue.

In the 'Spectator,' No. 78, Addison makes mention of 'the club, or rather the confederacy, of the Kings.' 'This grand alliance,' he observes, 'was formed a little after the return of King Charles II., and admitted into it men of all qualities and professions, provided they agreed in this surname of King, which, as they imagined, sufficiently declared the owners of it to be altogether untainted with republican and anti-monarchical principles.' A famous political club of those days was the King's Head Club, which is alluded to in Tate's continuation of Dryden's 'Absalom and Ahithophel.' It was a whig club; and the badge of its members was a green riband, in opposition to the tories, who wore a scarlet riband in their hats. (See Dryden's Works, by Scott, vol. vii., p. 154, and vol. ix., p. 380.)

The great age of clubs, political, literary, and of every other description, was the early part of the last century. Then flourished, among many others, the Brothers' Club, in which were associated Harley, Bolingbroke, Swift, and the other most distinguished literary and political characters of the day: the famous Scriblerus Club, of which Pope, Swift, and Arbuthnot were the leading members: the October Club, of the original institution and subsequent history of which an account may be found in Swift's 'Four last Years of the Reign of Queen Anne,' and also in a satirical pamphlet entitled 'The Secret History of the October Club, from its original to this time, by a Member,' 8vo., London, 1711: the Hanoverian Club: the first Beef-Steak Club, of which Mrs. Woffington, the actress, was president, being the only female member, and Richard Estcourt, the comedian, provisor, wearing in that character a small gridiron of gold, hung round his neck with a green silk riband: and, above all, the celebrated Kit-Cat Club, which is said indeed to have been instituted at the time of the trial of the seven bishops, in the reign of James II., but was in its greatest glory in that of Queen Anne.

In 1735 the second Beef-Steak Club, being that which still exists, and which has embraced among its members the most eminent public characters that have appeared since its institution, originated with Rich, the pantomimist, and the Earl of Peterborough. For an account of the circumstances, see an entertaining work entitled *The Clubs of London*, 2 vols., 8vo., London, 1828.

Of clubs of more recent institution, the most famous is the Literary Club, established in the year 1764, of which Johnson, Boswell, Burke, Reynolds, Goldsmith, and other well-known names, formed the list of members. Along with this may be mentioned the Essex Head Club, also founded a few years after by Johnson. It took its name from the tavern at which it met, in Essex Street. One of the most successful literary clubs of modern times was that called the King of Clubs, which began about the year 1801, and used to meet at the Crown and Anchor, in the Strand. An account of it is given in the second volume of the 'Clubs of London.'

The modern subscription houses which go by the name of clubs, such as the Athenæum, the University, the Senior and Junior United Service, and others of the same description, are in no other respect clubs, according to the antient English understanding of the term, except that every member must be balloted for, or admitted by the consent of the rest. And little more of the true character of a club belongs to those numerous political associations known as the Whig Club of Brookes's, the club at White's, the Carlton Club, &c. Political associations, in imitation of those existing in England, were formed at Paris in the earliest stage of the French revolution, and assumed the English name of clubs. The Breton Club, the Jacobin Club, the Club des Feuillans, and others, performed an important part in the various scenes of that extraordinary drama.

CLUB-MOSS, or **SNAKE-MOSS**, is a prostrate moss-like plant, with small scaly imbricated leaves, found in alpine or damp situations in most parts of the world. Its fructification consists of little two-valved cases, containing powdery matter. All the species belong to the genus Lycopodium; that to which the name is most commonly applied is L. clavatum.

CLUNY, a town in France, in the department of Saône et Loire; it is on the little river Grône, in a by-road, 200 miles in a direct line S.S.E. of Paris, in 46° 26′ N. lat., and 4° 39′ E. long.

Until the early part of the tenth century, Cluny was a mere village in the Mâconnois. In 910 Guillaume (William) I., duke of Aquitaine and count of Auvergne, who had purchased the village, founded an abbey of the Benedictine order. About twenty years afterwards St. Odon, second abbot of Cluny, introduced a reform into the Benedictine order, which reform spread very widely; and in course of time two thousand religious houses adopted the discipline of Cluny, which alone of those in which the rule was observed retained the rank of an abbey; the others were all simple priories, the abbots laying aside their title and rank. The Cluniac monks were divided into reformed and non-reformed, and the abbot of Cluny was the recognised superior of the whole order. The abbey was very extensive, and the number of the religious in the middle ages very large. The increase of the establishment may be judged of by the fact, that when, in A.D. 1245, Pope Innocent IV., accompanied by twelve cardinals, a patriarch, three archbishops, the two generals of the Carthusians and Cistertians [CHARTREUSE, CITEAUX], and the king of France (St. Louis) and three of his sons, the Queen Mother, Baudouin, count of Flanders and emperor of Constantinople, the duke of Bourgogne and six lords, visited the abbey, the whole party, ecclesiastical, royal, and noble, were lodged in the building of the monastery without disarranging the order of the monks, who amounted to four hundred. The abbot had the disposal of a great number of benefices, and of the priories of the different houses of the order. His archdeacon exercised all the functions of a bishop in the three parishes of the town of Cluny, except those of confirmation and ordination, until 1744, when the episcopal jurisdiction was transferred to the bishop of Mâcon The revenues of the abbot were stated by Expilly (1762) at 50,000 livres (about 2000*l.*) at least, and the revenue of the establishment (*la mense conventuelle*) at 70,000 livres (nearly 3000*l.*). The church of the monastery was one of the largest in the kingdom, built in the form of a cross, above 600 feet in length. The monastery was three times plundered by the Huguenots: before the last pillage the library contained 1800 manuscripts, and even after this event it was one of the richest in France; but it was dispersed or transferred elsewhere at the revolution, and the church destroyed. The monastery itself, a handsome modern building, has been appropriated to several public establishments, among which is a college or high school.

The town of Cluny is in a valley; it occupies as much ground as Mâcon, though far less populous. There is a stone bridge over the Grône, and before the revolution there was one religious establishment, besides the abbey, and two hospitals, one for the poor and one for the sick. The inhabitants in 1832 amounted to 3368 for the town, or 4152 for the whole commune: they manufacture coarse woollens, articles of furriery, and gloves; they trade in corn, wine, leather, and wicker-work. The valley affords pasturage, and produces grain and wine: alabaster and jasper are obtained from the neighbouring mountains.

CLUNY, ORDER OF MONKS OF; a branch of the Benedictines. William, Earl of Warren, son-in-law to William the Conqueror, brought these monks into England, and built their first house at Lewes, in Sussex, about A.D. 1077 or 1078. Tanner (*Notit. Monast.*, edit. Nasm. p. ix.) says there were twenty-seven priories and cells of this order in England. But a deputation of certain monks from the parent abbey of Cluny sent to King Henry VI., in 1457, to ask for the restitution of possessions in England, which they stated had been long detained from them, complained that they had been deprived of the obedience of thirty-eight. The number, of which an account is given in the new edition of Dugdale's 'Monasticon,' certainly amounts to forty-two, exclusive of three cells whose existence is not very distinctly known.

All the monasteries of this order in England were governed by foreigners, had more French than English monks in them, and were not only subject to the foreign houses of Cluny, La Charité sur Loire, and St. Martin des Champs at Paris, but could be visited by them only. None of their priors were elected by the respective convents, but were named by the above-mentioned foreign houses. They could not receive the profession of their novices in England. To have their differences determined, they were obliged, in almost all cases, to go to their superiors beyond sea; by which means the greatest part of their revenues were carried to those foreign houses: and upon that account, during the wars with France, the different establishments of this order were generally seized into the king's hands as alien priories. After a petition from a large number of the English Cluniac monks to the parliament at Winchester in the 4th Edward III., these inconveniences were by degrees removed; and some of their houses were in that and the following reign made denizen. Bermondsey, one of the greater houses of this order, was made an abbey; and all of them were at last discharged from all manner of subjection and obedience to the foreign abbeys. Tanner says this did not take place till 1457, when the deputation already mentioned, in addition to claiming the restitution of their possessions generally, desired leave to enter all places depending upon their houses; but instead of obtaining what they asked, they were deprived of the subjection of all houses of their order in England.

The houses of Cluny abroad had pensions from the houses of their order in England, called *Apportus*, which probably amounted in the whole to a large sum; for Cotton, in his 'Abridgement,' p. 51, says, the abbot of Cluny had a pension from England of 2000*l.* per annum; and according to Rymer, old edit., vol. iii. p. 1009, and Prynne's 'Records,' vol. iii. pp. 386, 858, the foreigners sometimes demanded occasional supplies from their houses here; and even ran them into debt, as stated by Prynne, vol. iii. p. 750.

The prior of Lewes, in Sussex, was accounted high chamberlain to the abbot of Cluny, and was often his vicar-general in England, Ireland, and Scotland. (See Rymer, old edit., vol. xi. p. 464.)

The greater part of the houses of the Cluniac order were founded prior to the reign of King Henry II. Slevesholm, in Norfolk, was the last founded, about A.D. 1222. Four houses of this order were among those which Cardinal Wolsey dissolved in 1525.

In D'Achery's 'Spicilegium,' fol. par. 1723, tom. i. p. 641, are the 'Antiquiores Consuetudines Cluniacensis Monasterii, collectore S. Udalrico Monacho Benedictino.' A detailed history of the origin and progress of this order abroad will be found in the 'Histoire des Ordres Monastiques,' tom. v. p. 184, which is translated in Stevens's Continuation of Dugdale's Monasticon. (Tanner, *Notit. Monast.* ut supra; Dugdale's *Monasticon Anglic.*, last edit. vol. v. p. 3.)

CLUPE'IDÆ, a family of fishes of the section Abdominales. The Clupeidæ are placed by Cuvier between the Salmonidæ and the Gadidæ: in fact they form the fifth and last division of his section 'Malacopterygiens Abdominaux.' The fishes of this division may be distinguished by their wanting the adipose fin, by having the upper jaw composed of the intermaxillary bones in the middle, and the maxillaries at the sides, and by the body being always covered with scales. Some of the species ascend rivers.

The genus Clupea, as now restricted by Cuvier, may be thus characterized:—maxillaries arched in front; opening of the mouth moderate; upper jaw entire; body compressed and covered with large scales; teeth minute or wanting. To this genus belong the Herring, Sprat, Whitebait, Pilchard, &c.

Clupea Harengus, Linn., the *Herring* (French, *Le Hareng commun*) is a fish well known; its characters however will be useful to distinguish it from some allied species; they are as follows:—

Small teeth in both jaws; suboperculum rounded; veins on the infra-orbitals and gill-covers; dorsal fin behind the centre of gravity; this fin commences about half way between the point of the upper jaw and the end of the fleshy portion of the tail; ventrals placed beneath the middle of the dorsal fin; tail forked; length of the head one fifth of that of the body; the greatest depth of the body one fifth of the whole length. The upper part of the fish is blue or green, according to the light; the sides, belly, and gill-covers are silvery white; ordinary length, ten to twelve inches.

The term Herring is the same as the German Häring, which, according to some, is derived from Heer, an army, and is applied to these fishes from their visiting the coasts in such immense numbers.

'The Herring inhabits the deep waters all round the British coasts, and approaches the shores in the months of August and September for the purpose of depositing its spawn, which takes place in October, or the beginning of November. It is during these months that the great fishing is carried on, for after the spawning is over it returns to deep water. The mode of fishing for Herrings is by drift-nets, very similar to those employed for taking mackerel and pilchard, with a slight difference in the size of the mesh. The net is suspended by its upper edge from the drift-rope by various shorter and smaller ropes, called buoy-ropes; and considerable practical skill is required in the arrangement, that the net may hang with the meshes square, smooth and even, in the water, and at the proper depth; for according to the wind, tide, situation of their food, and other causes, the herrings swim at various distances below the surface.'

'The size of the boat used depends on the distance from shore at which the fishery is carried on; but whether in deep or in shallow water, the nets are only in actual use during the night. It is found that the fish strike the nets in much greater numbers when it is dark than when it is light: the darkest nights therefore, and those in which the surface of the water is ruffled by a breeze, are considered the most favourable. It is supposed that nets stretched in the daytime alarm the fish, and cause them to quit the places where that practice is followed; it is therefore strictly forbidden [*].'

The young are found on our coast during the summer months in great abundance, and are often taken in small-meshed nets used for catching other fishes.

The food of the herring consists principally of small crustacea, but they have been known to devour the fry of their own species.

Clupea Leachii (Leach's Herring). This second species of herring was discovered by Mr. Yarrell, and described in the proceedings of the Zoological Society for 1831, p. 34. An account by the same gentleman is also given in the Zoological Journal, vol. v. p. 278, where a figure of the species will be found. We will therefore give the distinguishing characters in Mr. Yarrell's own words.

'The length of the head compared to that of the body alone, without the head or caudal rays, is as one to three; the depth of the body greater than the length of the head, and compared to the length of the head and body together, is as one to three and a half; it is therefore much deeper in proportion to its length than our common herring, and has both the dorsal and abdominal lines much more convex: the under jaw longer than the upper, and provided with three or four prominent teeth just within the angle formed by the symphasis; the superior maxillary bones have their edges slightly crenated; the eye is large, in breadth full one-fourth of the length of the whole head; irides pale yellow; the dorsal fin is placed behind the centre of gravity, but not so much so as in the common herring; the scales are smaller; the sides without any distinct lateral line; the edge of the belly carinated, but not serrated; the fins small. The fin-rays in number are—dorsal, eighteen; pectoral, seventeen; ventral, nine; anal, sixteen; and caudal, twenty. Vertebræ, fifty-four.

'The back and upper part of the sides are deep blue, with green reflections, passing into silvery white beneath. The flesh of this species differs from that of the common herring in flavour, and is much more mild.'

Mr. Yarrell first discovered this species when examining the various kinds of fishes caught by the fishermen whilst engaged in taking sprats.

Clupea Sprattus, the *Sprat*, called in France *Le Melet*, *Esprot*, or *Harenguet*. This fish has by many authors been confounded with the young of the herring; it is however distinct, and its characters were first pointed out by Pennant; they are as follows:—proportions nearly the same as those of the herring, but the depth of the body is greater in proportion than in the young of that species; the gill-covers are not veined; the teeth of the lower jaw are so minute as to be scarcely visible to the touch. The dorsal fin is placed farther back, and the keel to the abdomen is more acutely serrated than in the herring.

Sprat-fishing commences in the early part of November; hence in season they immediately follow herrings, and the markets continue to be supplied with them during the winter months. Like the herrings, these fishes inhabit the deep water during the summer: they are so plentiful as to be frequently used for manuring the land, and are often sold as low as sixpence per bushel.

Clupea alba (Yarrell), the *White-Bait*; French, *Blanquette*; German, *Brietling*. This fish has been supposed to be the young of the shad: Mr. Yarrell, however, upon a careful investigation of the subject, ascertained it to be a distinct species: its distinguishing characters are—length of the head compared with that of the body, and not including the tail, as two to five; depth, as compared to the whole length of the fish, as one to five; keel of the abdomen distinctly serrated, but not so sharp as in the *shad*. The dorsal fin commences half way between the tip of the muzzle and the end of the tail; the upper jaw is slightly crenated, the lower jaw is the longer and smooth. Its colour is silvery white, growing greenish on the back; the body is more compressed than in the herring, and the keel to the abdomen is more sharply serrated than in either that fish or the sprat.

The White-bait is caught in great abundance in the Thames as high up as Woolwich and Blackwall; the fishing commences about the beginning of April, and is continued to September. 'When fishing as high as Woolwich,' says Mr. Yarrell, 'the tide must have flowed from three to four hours, and the water become sensibly brackish to the taste, before the white-bait will be found to make their appearance. They return down the river with the first ebb-tide; and various attempts to preserve them in well-boats in pure fresh water have uniformly failed.' The food of the white-bait consists of small crustacea.

Clupea pilchardus, the *Pilchard*; *Le Célan*, in France. In size this fish resembles the herring; it is also nearly of the same form, but rather thicker, and of greater proportionate depth; the scales are larger, the head is shorter, the suboperculum is square, and the dorsal fin is more forward in position: the gill-covers are distinctly veined.

This fish is caught off the coast of Cornwall in great abundance; the fishing commences in July [*]. The food of the pilchard consists of small shrimps, and other crustaceous animals.

The *Shad* is another fish belonging to this group; it is however placed in a sub-genus called by Cuvier *Alosa*. He separated this, together with several other species, from the true Clupeæ, from the circumstance of their having the upper jaw deeply notched in the middle.

Two species of shad are found off the British coast; the first (the *Twaite Shad*, Yarrell) known generally by the name of *Shad* (Alosa finta), is about fourteen inches in length; its colour is brownish-green on the back, or inclining to blue in certain lights; the rest of the body is silvery; five or six dusky spots are observed on each side, and are disposed longitudinally, the first close to the head, and the others at short intervals; the length of the head as compared with the body is as one to five; the body rather exceeds this measurement in depth; the jaws are furnished with distinct teeth, and the tail is deeply forked.

This fish is found in the Severn and Thames in tolerable abundance. The principal fishing season for the shad in the Thames is about the second week of July: they begin to ascend the river about May for the purpose of depositing their spawn, and this being done they return to the sea about the end of July.

In former times the shad was caught as high up the river as Putney: it now rarely passes London Bridge, and is caught in the greatest abundance a little below Greenwich. Its flesh is dry, and therefore not much esteemed for the table.

The second species of shad, the Allice, or Allice Shad of Mr. Yarrell (*Alosa communis*), is considerably larger than the one just described, being from two to three feet in length: it may moreover be distinguished by its having only one spot on the side of the body, near the head, and that is sometimes scarcely visible: the jaws have no distinct teeth, and the scales of the body are rather smaller in proportion, though they are large in both species.

The Allice Shad is plentiful in the Severn, but of rather rare occurrence in the Thames.

CLUVE'RIUS (CLUWER), PHILIP, was born at Danzig, in 1580. His father intending him for the profession of the law, sent him to study at Leyden: but Cluverius showed more disposition for the study of geography and antiquities, and was encouraged in his bias by his acquaintance with Joseph Scaliger. In a journey which he made to Louvain and Antwerp, for the purpose of meeting Justus Lipsius, he fell in with some marauding soldiers, who stripped him of everything. On his return to Holland, finding that his father, being dissatisfied with his conduct, had stopped all remittances for his support, he joined the troops of the emperor, and served for two years in Hungary and Bohemia. In the latter country he made the acquaintance of a Baron Popel, who being arrested by order of the emperor, had written a pamphlet in his defence, which Cluverius undertook to translate into Latin, and published it on his return to Holland. The pamphlet being considered offensive, Cluverius was imprisoned, at the request of the imperial ambassador to the States General. He was soon after released, and his mother having sent him some supply of money, he set out on his travels to England, where he wrote 'De Tribus Rheni Alveis,' 4to. Returning to the continent, he travelled through France and Germany, and published his 'Germania Antiqua,' fol., Leyden, 1616. It is a work of considerable research, intermixed with much conjecture. Having made a journey into Italy, he was well received there, especially at Rome and Bologna, where his familiar acquaintance with most of the European languages excited great admiration. His next work, 'Siciliæ Antiquæ Libri Duo,' to which he added a short description of Sardinia and Corsica, fol., 1619, has been considered by many as his best work. On his return to Holland from Italy he suffered severe domestic losses, and his health rapidly declined. It was under these circumstances that he wrote his 'Italia Antiqua,' which was published after his death. It is a work of great research, and is still one of the best on the geography of antient Italy, although it occasionally requires correction from the more exact observations or discoveries of later geographers and antiquarians. Cluverius's friend and fellow traveller, Lucas Holstenius, added to it his own observations. Cluverius wrote also 'An Introduction to Universal Geography,' which has been repeatedly published. He died at Leyden in 1623, forty-three years of age. Danielis Heinsii *Oratio in obitum P. Cluverii*, at the end of the 'Introduction to Geography,' Leyden, 1624, gives an account of the principal incidents of Cluverius's life.

---

[*] From Yarrell's 'History of British Fishes,' to which we refer our readers for a more detailed and interesting account of this and the other species here noticed.

[*] 'The number of fish taken by a drift boat in a night's fishing varies exceedingly; from five to ten thousand is considered moderate; it often amounts to twenty thousand. For the season's fishing, about one hundred and fifty thousand fish would be deemed favourable.'—Yarrell's 'British Fishes.'

CLWYD, a river in North Wales, in the counties of Flint and Denbigh. It rises on the eastern declivity of the Bronbanog hills, a ridge belonging to the Hiraetog hills, and its upper course for a few miles is to the S. It then suddenly turns E.N.E., and continues nearly eight miles in that direction. About three miles above Ruthyn it declines to the N., and preserves this course to its mouth. The upper third of its course is through a narrow valley, which presents some very fine views. Below Ruthyn it enters the fertile vale of Clwyd, which extends upwards of fifteen miles in length, and is a pretty level tract from five to seven miles wide. Being studded with towns, villages, and seats, covered with verdant meadows and luxuriant fields, and enclosed on every side by brown and barren hills, this vale offers by the contrast a very pleasant view. A little below St. Asaph, the Clwyd is joined by the Elwy, which traversing a hilly tract brings to it a large mass of water, and the river below this town increases considerably in breadth. It soon afterwards enters the fertile and extensive marsh of Rhuddlan, called Morva Rhuddlan: three miles below the town of Rhuddlan it enters the sea through a small æstuary opening northward, and forming a port for small coasting vessels. The whole course of the river may be about thirty miles; it is navigable for flat-bottomed boats of about seventy tons up to Rhuddlan quay.

CLYDE, a river in Scotland, the third in magnitude, but the most important for its navigation. Its sources lie between 55° 18′ and 55° 28′ N. lat., where the highest summits of the mountain-range traversing South Scotland, the Lowthers (3150 feet), the Lead Hills, Queensberry Hill (2259 feet), and the range connecting the latter with Hart Fell (2790 feet), form nearly a semicircle. The rivulets which descend from this range unite in one stream about 55° 27′, and thus the Clyde is formed. The most southern and largest of these streams is the Daer; but another smaller stream is called Clyde, before the union. After the junction of these streams, the Clyde continues in the direction of the Daer northwards to Roberton, twelve miles lower down: in the whole of this part of its course the current is very rapid, and preserves the character of a mountain-stream. North of Roberton, the Tintoc Hills (2310 feet high) direct its course north-east; at Biggar its course is changed to the north-west and north, but below Roberton it flows west-south-west to its confluence with the Douglas Water, and accordingly it makes a large bend round the Tintoe Hills. Its course in this distance is little short of twenty miles, though Roberton and the mouth of the Douglas Water are only six or seven miles distant in a straight line. The valley through which it flows is wide, and the current is so gentle that in some places it is hardly perceptible. After the junction with the Douglas Water the rapidity of the stream increases, and the falls commence. The first is the Bonniton Linn, a cascade about thirty feet high, which is followed by the Corra Linn, where three waterfalls occur near one another, each apparently as high as Bonniton Linn. The rocks on both sides narrow the bed of the river so much, that the waters in some places rush down a chasm not more than four feet wide. Corra Linn is two miles above the town of Lanark. Two miles lower down is Stonebyres' Fall, which also consists of three distinct falls, altogether measuring about seventy feet in height. The scenery near the falls has considerable beauty. It is probable that the river in a space of about six miles descends not less than 230 feet, and the valley of the river above the falls may be about 400 feet above the sea. Below the falls, the river, continuing its north-west course, runs in a fine valley to Blantyre and Bothwell, the lands rising in a gentle ascent on both sides. Farther down its banks are sometimes bold and richly wooded: sometimes they extend in level plains. At Glasgow the Clyde has a considerable width, and vessels ascend to the Lower Bridge of Glasgow. From Glasgow to the vicinity of Dumbarton it runs through a level country. At no great distance from the castle of Dumbarton the Kilpatrick Hills rise on the north, and the Renfrew Hills on the south. Between these ranges the Clyde forms a wide æstuary, which at Dumbarton is about a mile across, and widens in its progress to the west, being at Greenock more than two miles in breadth. To the west of the latter place at Cloch Point it turns abruptly to the south, and reaches the sea by the two straits which lie between the island of Bute, the Cambray islands, and the coast of Ayrshire. The river south of Cloch Point is called the Firth of Clyde, a term which is frequently extended to that part of the sea which lies between the island of Arran and the coast of Ayrshire. The whole course of the Clyde, from the source of the Daer to the southern extremity of the island of Bute, may be about 100 miles.

CLYSTERS (the Greek *κλυστήρ*), lavemens, or enemata, terms bestowed upon medicinal agents introduced into the rectum, or lower bowel, with the intention of expelling its contents, or producing other local effects, but also occasionally to influence the system generally. The intestinal canal, from its commencement at the mouth to its termination in the rectum, is endowed with peculiar sensibilities; and though each portion of it has some special office, yet the whole responds to certain stimulants, whatever part they may be applied to. Thus purgative medicines may be introduced into it either by the mouth or by the rectum, and to a certain extent their action is the same, *i. e.* both will occasion an expulsion of the contents of the lower bowel; but the secondary influence on the system will be different, inasmuch as when the purgative is given by the mouth, during the whole course of its descent it produces, according to its nature, a special action on each portion as it passes, frequently causing an increased secretion of serum, and so materially affecting the general system. But when the same substance is introduced by the rectum, it only produces a local effect, by bringing about the expulsion of the contents, and influencing the system generally only when these were of such a nature as to occasion irritation by their retention. Clysters are also employed to assist in retaining the contents of the bowels when they are expelled too frequently, as in many cases of diarrhœa. Clysters of this latter kind are likewise used to aid in retaining the contents of some of the neighbouring organs, such as of the uterus, in cases where abortion is threatened; and are also employed to allay pain and irritation in the bladder, kidneys, &c. Further, when the mouth or upper part of the throat is closed, as in spasmodic diseases, such as lock-jaw, or from tumours or paralysis, they are frequently made the vehicle for introducing either food or medicine into the system. The only other point requiring notice here is the fact that as the sensibility of the rectum is considerably less than that of the stomach, the doses of most articles given as clysters must be greater than when administered by the mouth.

Clysters are rarely, except in two instances, taken or administered without the order or superintendence of a competent medical attendant, and therefore we shall confine our observations chiefly to those two cases. The first and most common is where persons employ them for the relief of constipation; for this purpose tepid water or gruel is, by means of a proper instrument, thrown up into the rectum, and when a suitable quantity (about a pint) is used, it is generally speedily returned, bringing with it the other contents of the lower bowel. To the occasional use of such means no objection can be urged; but if employed habitually, and as a substitute for the efforts of nature, the greatest injury will result. Constipation does not in general depend upon a want of power in the rectum to expel its contents, but upon the use of improper diet, or a deficiency of the secretions of the upper part of the intestinal canal, such as the bile, which furnishes the natural stimulus to the intestines; and clysters never can effectually supply the want of these secretions. By the abuse of clysters, the tone of the whole alimentary canal may be lost, and the process of nutrition so impaired that wasting and other serious consequences have followed. Clysters even of the mildest kind should therefore be restricted to the accomplishment of temporary and occasional purposes. At the commencement of fevers and other inflammatory complaints, the speedy evacuation of the contents of the rectum is desirable; and where medicines cannot be taken by the mouth, owing to the irritability of the stomach causing their rejection, clysters of purgative substances, such as castor oil, or infusion of senna with sulphate of soda, may be used. For the relief of spasmodic diseases, clysters of the fetid gums, such as assafœtida; or of oil of turpentine, may be used. Sometimes tobacco in the form of infusion or of smoke is employed; but this requires the greatest care. The second case to which we have alluded, in which clysters are employed without medical superintendence, is that of tobacco-smoke thrown into the rectum of drowned persons: a more hurtful measure cannot be adopted; it is now abandoned by all intelligent persons.

Where clysters are employed to allay pain, or arrest premature action of the uterus, they generally contain tincture of opium, and are of small bulk; about a quarter of a pint of starch serves as the vehicle. Where nourishment is the object, they are also of small bulk; about half a pint of beef-tea alone, or with powdered cinchona bark, and a few drops of laudanum. Substances introduced into the rectum in a solid form are called suppositories.

CLYTHRA, a genus of Coleopterous insects, of the family Chrysomelidæ. The insects of this genus generally have the body more or less cylindrical; the antennæ short, with the basal joint thick, the two following joints short, and the remaining (with the exception of the apical joint) serrated, *i. e.*, produced internally, so as to resemble the teeth of a saw. The head is placed vertically, and inserted into the thorax, so as to be scarcely visible from above: often larger in the male than the female. The legs are moderately long, rather thick; in the males the anterior pair are often considerably larger than the two posterior pairs: the penultimate joint of the tarsi is bilobed.

The larvæ of these insects (at least those that are known) inhabit a coriaceous tube, which they drag about with them.

The Clythræ reside on trees and shrubs, and those found in this country appear in the beginning of the summer. The species are very abundant, and seldom adorned with metallic colours. In England we have five species, the most common of which is *Clythra quadripunctata:* this is not quite half an inch in length, and black; the elytra ochre-coloured, with four black spots, two near the base, and two near the middle. The next species which is not uncommonly met with is *Clythra tridentata*. This beetle is rather less than the last, and of a blue-green colour, thickly an finely punctured above; the elytra are pale-yellow and immaculate; the anterior pair of legs in the male are elongated.

CLY'TUS, a genus of Coleopterous insects of the section Longicornes, and family Cerambycidæ.

The species of the genus Clytus (a genus established by Fabricius) form a well-marked group among the Cerambycidæ, and are chiefly distinguished by their having the palpi short and nearly equal, the terminal joint thicker than the others, and truncated at the apex; the head narrower than the thorax, and the latter nearly globular or approaching to a cylinder. The body is elongate, and nearly cylindrical; the antennæ are shorter than the body, and filiform; the basal joint is rather thick; and the terminal joints are sometimes incrassated; the legs are moderately long.

These insects are generally of moderate size, and have the elytra adorned with arcuated fasciæ; their ground colour is usually black or brown, and the markings yellow.

About ninety species of this genus have been discovered, and they appear to inhabit every quarter of the globe: five are recorded as British, of which the more common are *Clytus mysticus*, *C. Arietis*, and *C. arcuatus*. *Clytus mysticus* is about half an inch in length; colour black; the base of the elytra red-brown; three bent white fasciæ are situated near the middle of the elytra; and there is a white patch at the apex. This species is common in the neighbourhood of London. We have frequently found its larva in the rotten wood of old blackthorns.

C. Arietis is about the same size as the last; its colour is black; legs and base of the antennæ reddish; the former with the thighs of the two anterior pairs blackish; thorax with a yellow band on the anterior part, and another on the posterior; scutellum yellow; elytra with four yellow bands.

This insect is frequently met with in gardens and woods in the neighbourhood of London and elsewhere. When handled it makes a peculiar noise, which seems to be produced by the friction of the thorax against the smooth part of the abdomen which is inserted in that part. Many of the Cerambycidæ have this power.

C. arcuatus is less common than either of the preceding species; it somewhat resembles *C. Arietis*, but is considerably larger and broader in proportion. The antennæ are entirely of a reddish-yellow colour; the legs are coloured as in the last-mentioned species; the thorax has a yellow band on the fore part, and an interrupted band in the middle; the elytra have three yellow bands, and towards the base three spots of the same colour; the scutellum is also yellow.

CNIDUS was a city of Caria on the S.W. coast of Asia Minor, at the extremity of a peninsula between the Sinus Ceramicus, or gulf of Cos, and the gulf of Syme, and facing the south part of the island of Cos, which is 10 miles west of Cape Crio, or Triopium, near which Cnidus stood. (Leake's *Asia Minor;* and Beaufort's *Survey of the Coast of Caramania.*) Cnidus is about 25 miles south of Halicarnassus. It was a Dorian colony, like Cos, Halicarnassus, and the other towns which formed the Dorian confederation of the Hexapolis. (Herod. i. 144.) It had two harbours divided by a narrow isthmus which joins Cape Crio to the mainland. The remains of two moles which enclosed the south or larger harbour are still visible, as well as those of the city walls, and a multitude of other ruins. (Beaufort's *Plan of Cape Crio*, in the last plate of his *Survey.*) Leake says, that 'there is hardly any ruined Greek city in existence which contains specimens of Greek architecture in so many different branches. There are still to be seen remains of the city walls, of the closed ports, of several temples, Stoæ, artificial terraces for public and private buildings, of three theatres, one of which is 400 feet in diameter, and of a great number of sepulchral monuments. Designs of the most important of these curious remains are about to be published by the Society of Dilettanti.' (Leake's *Asia Minor* 1824.)

Strabo (xiv.) speaks of an observatory at Cnidus, and he mentions among the distinguished natives of the place, Eudoxus the mathematician, a contemporary of Plato; Ctesias, physician to Artaxerxes, who wrote on Syrian and Persian history; and the peripatetic Agatharchides, a friend of Julius Cæsar. He also says that Lipara, near Sicily, was a colony of Cnidus. He says nothing about the celebrated temple of Venus, said by some to have existed at Cnidus, but Cicero mentions, among the numerous works of art seized by Verres, a marble Venus from Cnidus. (*In Verrem*, iv. 60.)

COACH. It is stated by Stow, that in '1564, Boonen, a Dutchman, became the queen's coachmanne, and was the first that brought the use of coaches into England.' Anderson (*Hist. of Com.*), on the other hand, says that 'about 1580 the use of coaches was introduced by the earl of Arundel.' 'Before that time (Hume, *Hist. of Eng.*) the queen (Elizabeth) on public occasions rode behind her chamberlain.' A long time elapsed before this luxury was attained by more than a few very rich and distinguished individuals, and a very much longer time before coaches became general. Coaches let for hire were first established (Anderson) in England in 1625. They did not stand in the streets, but at the principal inns. In 1637 there were, in London and Westminster, 50 hackney coaches. Stage coaches were first used in England soon after the introduction of hired carriages. In Scotland, in 1678 (Cleland, *Statis. of Glasgow*), Provost Campbell established a coach to run from Glasgow to Edinburgh, 'drawn by sax able horses, to leave Edinboro' ilk Monday morning, and return again (God willing) ilk Saturday night.' The first mail coach travelled from London to Edinburgh about 1785, and to Glasgow in 1788. The Scotch custom of the male passengers treating the female to breakfast and dinner on the road continued till these coaches were established.

The public are now so familiarized with the use of stage coaches that they are apt to forget that their origin is so recent. At the present time there is scarcely any small town through which some stage-coach does not pass, and no considerable road which is not travelled by many. Until the invention of springs, a man's endurance was the measure of his journey: it was impossible to travel fast, on account of the weight of the carriage; it was equally impossible to travel far, since no one could long bear the direct and unmitigated jar. Springs were the first means towards better travelling; since their invention, the increased speed and better appointment of English stage-coaches have been caused by the improvement of roads in conjunction with the great demand for rapid travelling. In this country the best stage-coaches are very perfect machines, and the arrangements by which they are conducted, when the number of persons and animals that are engaged comes to be considered, are extremely complete. The attendant expenses are very large, but are defrayed wholly by private speculators, excepting in the case of *mail* coaches, which convey the letters, the contractors for which, in consideration of certain services, receive an allowance from the state. The stage-coaches themselves usually belong to a coachmaker, who contracts with the speculators who 'work' them, for the supply of new carriages at certain intervals, and is liable to the expense of all repairs: for this he receives 2½*d.* or 3*d.* for every mile they travel. There is a duty per mile according to the number of passengers to be carried, rising from 1*d.* a mile for 4 persons, to 4*d.* a mile for 21[*]. For each coachman a duty of 1*l.* 5*s.* is annually paid, and for each guard, excepting those of mails. The expense of *horsing* a four-horse coach running at the speed of from nine to ten miles an hour, may be stated at 3*l.* a double mile for 28 days (a lunar month); so that a person horsing ten miles of a coach passing backwards and forwards each day, should earn or receive by way of remuneration 13 times 30*l.*, or 390*l.* a year for his work. This may be considered a high rather than a low estimate, unless in a district where wages and rent of stables are high, and hay and corn dear. In a cheap neighbourhood, or where a large number of horses are kept, the expense will not be so great. Nevertheless a great many articles are to be provided: harness, which for four horses costs from 16*l.* to 20*l.*: horses, of which, for ten miles of ground, at least eight in summer and nine in winter will be required; their price will be from 5*l.* to 20*l.* each: corn and beans, of which each horse will eat little less than two bushels a week, together with hay and straw cut into chaff. Straw, shoeing, physic, and farriery, must also be reckoned, as well as stabling, stable utensils, and horsekeepers' wages, which for each man are from twelve to fifteen shillings a week. The firm must also defray the wages of coachmen, who receive about ten shillings a week, unless they drive backwards and forwards, and take fees from two sets of passengers each day, when they get no wages. The charge for washing the coaches must also be reckoned. To this long list must be added the heavy item of turnpikes. Mails are exempt from turnpike tolls, but a tax is paid for them to the government, and mileage to the contractor for the use of the coach. The Post-office allows them, according to their speed and the country through which they travel, from 4*d.* to 6*d.* a mile for carrying the letters; in consideration of this, it claims a right to limit their number of passengers, and regulate their speed and time of starting: the guard is the servant of the Post-office. Booking-offices and book-keepers and advertisements are also to be paid for, as well as way-bills. One of these, on which the name and destination of each passenger and the direction of each parcel are inserted, is carried by the coachman, and delivered as soon as the coach stops to each proprietor or book-keeper, that he may examine its correctness and make any requisite entries. In the country nothing is paid to the booking-offices, but in London this is not the case: from 3*l.* to 4*l.* a (lunar) month is charged when the office is a mere shop for the purpose of booking, and does not belong to any coachmaster: if it is the property of a coachmaster, he takes 1*s.* for booking out of the fare of each passenger booked at his offices.

Some approximation to the expenses of coaching may be made from the above statement. The returns will not so easily be calculated. They consist of the fares, which are usually, for the outside passengers, at the rate of from 2½*d* to 3*d.* a mile; for the inside somewhat less than twice this amount: the fares of mails are usually higher. Very arbitrary charges are made for parcels according to their size and weight. These however are not all the profits arising from stage coaches: the custom which they bring to inns must be reckoned a large item, when the proprietor is the owner or renter of an inn; and especially when the coach 'ends' at his house; and thus, though a coach may itself be worked at a loss, all things considered, to some of its proprietors at least it may be a remunerating speculation. The proprietors at the ends have obviously the greatest chance of profit; for nearly every passenger must spend something, however small, at their inn. They have likewise a greater advantage in porterage, and often get a profit from advertising, printing way-bills, and washing coaches, all of which are managed by them: they also get interest for the money that is earned by the coach, which remains in their hands until the monthly division among the proprietors.

The fastest coaches now travelling are between—

London and Shrewsbury . .	154	miles,	in one day.	
„ Exeter . . .	171	„	„	
„ Manchester . .	187	„	„	
London and Manchester (mail)	187	„	19h.	0m.
„ Holyhead (mail)	261	„	26	55
„ Liverpool (mail)	203	„	20	30

The Edinburgh, the Leeds, and the Devonport mails are also very rapid.

Short stage coaches, plying in the neighbourhood of towns, have been nearly superseded by omnibuses.

By an Act passed in 1833, coaches and omnibuses are allowed to ply for hire in the streets of London.

The coaches which form the trains upon rail-roads are of very different construction from those used on common roads: they are stronger, larger, heavier, and lower, the wheels being of smaller diameter: they are fastened together with links of chain, and there is attached to the back and front of each a 'fender,' acting on a spiral spring, by which concussion is prevented when the train is stopped. Some carriages adopted on the Greenwich Rail-Road seem to be of an improved construction: they are lower than those hitherto used; and as long as they remain upon the rail it would be very difficult to overturn them, even though the axles were to break, or the wheels come off.

Upon the continent, travelling in public carriages is not so rapid or so commodious as in England. The state of the road is in general such as to preclude any considerable speed, and to require great strength in the coaches.

In France the diligences are conducted by private speculators, who are obliged to use the horses of the Poste Royale. They are clumsy carriages, generally consisting of three bodies, and are drawn by five or six horses, usually driven by one postilion from his saddle. The first body, called the 'coupé,' formed like a chariot, contains three people; the second, which is like a coach, the 'interieur,' holds six persons; the third, which is similar to a coach turned sideways, carries six or eight passengers, and is called the 'rotonde.' In addition to these, there is on the roof, before the place appropriated to the luggage, the 'banquette,' a bench sometimes furnished with a hood for the accommodation of four passengers. Should all these places be filled, the 'conducteur,' or guard, sits upon the luggage. The speed of these carriages is from four to five (English) miles an hour: the fares vary according to the part of the vehicle in which the place is taken; the 'coupé' being the dearest; the 'intérieur' the next; and then the 'rotonde' and the 'banquette.' The fare in the 'coupé' is rather more than half that of an outside place in England; but a large additional charge is often made to each passenger for all luggage above 30lbs. in weight. The malle-postes, by which the letters are conveyed, are conducted by the government. They are the fastest and best appointed public carriages on the continent. Their speed is at least eight miles an hour: they are drawn by horses of the Poste Royale, and carry one person in the cabriolet, with the courier, and two persons in the second body, or calêche. The fares are considerably higher than in the diligences.

---

[*] The duty was formerly levied according to the number of miles travelled, without regard to the number of passengers. It would have been well, when the law was altered, either to have limited the capability of accommodating on each coach more persons than it was licensed to carry, or to have increased the penalties for a breach of the statute. The revenue is now greatly defrauded.

Stage coaches (Schnell-posten) in Prussia are entirely in the hands of the government, which imposes a number of regulations, some of which cause considerable inconvenience. They consist of a 'cabriolet' in front, containing three persons; and an 'intérieur,' which holds nine people on three rows: the conducteur sits inside. These are the best foreign conveyances, excepting the mails: they stop less than the French, and travel about six miles an hour. The fares are about the same as for the outside of an English coach: luggage above 20lbs. is paid for extra, and if above 40lbs. weight, is sent in a slower and separate conveyance from the passenger. The letters are carried by the common coaches. In Italy the diligences are the property of individuals who purchase from the government the monopoly of a certain road. The mails, which are very similar to the French, are nearly as fast, and rather more expensive. Travelling by 'Vetturino' is the most common and cheapest method. In this case the driver agrees to carry the passenger from place to place in a given time, and for a given sum, all expenses on the road being generally included.

In Belgium the diligences are similar to, though faster than the French. In Spain there are not above six or seven roads on which diligences travel. They are monopolized by a privileged company, in which Ferdinand, the late king of Spain, and his queen, had shares. The carriages consist of a coupé and intérieur similar to the French: there are also two places on the back of the roof, on which are seated two guards armed with carbines; the conductor is called the 'mayoral.' Their speed is from five to six miles an hour. The mails travel faster: a person leaving Bayonne (1833) at twelve o'clock on a Friday, reached Vittoria the next morning, and remained there till the afternoon; at daybreak on Sunday he reached Burgos, and arrived at Madrid on Monday morning. The cabriolet in front contains one passenger, the courier, and the mayoral, and the calêche two more passengers.

In the United States of America the travelling has improved rapidly of late years, and on the best roads the public conveyances are superior to any other except the English. Some of the coaches contain accommodation for nine persons, six of whom sit on two opposite benches as in our coaches, and the other three on a seat parallel to and between the other two benches, with a leather strap drawn tight across the coach to support their backs. The body of these coaches is consequently larger than in the English coaches. Other coaches contain only two seats like the English, but no places for passengers on the top. In 1792 Mr. Jefferson, then secretary of state, wrote to the post-master-general to know if the post, which was then carried at the rate of fifty miles a day, could not be expedited to one hundred; but even this latter rate would now be considered intolerably slow on the great post-roads. (Tucker's *Life of Jefferson*, vol. i., p. 376.)

COAGULATION, the solidification of a liquid produced without evaporation and without crystallization. It is also often effected without reducing the temperature of the substance coagulated, in which it differs from mere congelation.

Coagulation occurs in various ways in different fluids. Thus when albumen, or the white of egg, is heated, it is rendered solid or it coagulates; but when a solution of gelatin cools, it undergoes a similar change. The cause of the spontaneous coagulation of the blood, by which it is resolved into serum and coagulum has not been explained, and we are equally in the dark as to the immediate cause of the coagulation of cheese by the action of rennet; the separation of butter is attended with heat, and the immediate cause is mechanical action.

There are some cases of pure chemical action which resemble coagulation in appearance; when, for example, solutions of sulphate of soda and nitrate of lime are mixed, a sudden solidification takes place: but this is probably a case of confused crystallization, and not, strictly speaking, of coagulation.

COAITA. [ATELES, Species 1, vol. ii. p. 547.]

COAL, COMPOSITION OF. From the very different qualities of the several varieties of coal, it might naturally be expected that they would vary in composition, and this is actually found to be the case. They generally agree however in containing a much larger proportion of carbon than of the other elements, which are chiefly oxygen and hydrogen, and frequently a small portion of azote.

The composition of coal may be regarded under three different points of view: first, as to the quantities of combustible matter and earthy impurity; secondly, as to the mode in which the pure constituents of the coal are combined; and thirdly, as to its ultimate analysis.

With respect to the first, we shall state a few of the results obtained by Mr. Mushet.

	Volatile Matter.	Charcoal.	Ashes.
Derbyshire cannel coal .	47·000	48·362	4·638
Scotch · ditto .	56·570	39·430	4·000
Welsh furnace ditto .	8·500	88·068	3·432
Ditto stone ditto .	8·000	89·700	2·300
Kilkenny coal . .	4·250	92·877	2·873

Macquer had observed that nitre does not detonate with oily or inflammable matter till it is reduced to coal, and then only in proportion to the carbonaceous matter which it contains. Following this opinion, Kirwan imagined that he might be able to distinguish the quantity of bitumen and maltha from that of mere carbon which the coal contained by deflagration with nitre. The method is not susceptible of great precision, but the following results are worth recording:—

	Charcoal.	Bitumen.		Earth.
Kilkenny coal .	97·3	0		3·7
Compact cannel .	75·2	21·68	Maltha	3·1
Swansea . .	73·53	23·14	mixt.	3·33
Wigan . .	61·73	36·7	do.	1·57
Newcastle . .	58·00	40·0	do.	—
Whitehaven .	57·00	41·3		1·7

The following are the results of the analyses of some varieties of coal:—

Analyst.		Carbon.	Oxygen.	Hydrogen.	Azote.
Karsten.	Newcastle coal	84·99	11·78	3·23	
Ditto.	Cannel coal .	74·83	19·72	5·45	
Crum.	ditto ditto .	70·9	24·80	4·30	
Ure.	ditto ditto .	72·22	21·05	3·93	2·8

As during the preparing of carburetted hydrogen gas from the decomposition of coal, a quantity of ammonia is generally, if not always, produced, it must in these cases contain ammonia, as shown in Dr. Ure's analysis. According to Dr. Thomson, indeed, who seems however to have overrated the quantity, caking or bituminous coal gives nearly 16 per cent. azote, and cannel coal above 13 per cent. of the same element; whereas Karsten and Crum find none, and Dr. Ure only 2·8 per cent. It is therefore probable that different kinds of coal have been analyzed under the same name; and the subject requires further investigation.

COAL-FIELDS, a term used to express those extensive carbonaceous deposits which are found in many parts of the world, but more especially in our own island. The following article is limited to a description of the various coal-fields of the United Kingdom, together with a short notice of the locality of coal-fields in other parts of the world.

The following general arrangement of the coal-fields of England and Wales, which is offered by Messrs. Conybeare and Phillips, seems to be as good and natural a classification as can be adopted. 1. The great northern district, including all the coal-fields north of the Trent. 2. The central district, including Leicester, Warwick, Stafford, and Shropshire. 3. The western district, which may be subdivided into north-western, including North Wales, and south-western, including South Wales Gloucester, and Somersetshire.

Coal is found in these fields in strata of various thickness, alternating with slate-clay and sandstone; the alternations being frequently and indefinitely repeated. The coal-beds, which are of various qualities, are principally distinguished by the proportion of bitumen in the coal. Three species are enumerated, in each of which the quantity of bitumen has been ascertained. 1. The caking coal, likewise distinguished by many other provincial names, yields about forty per cent. of bitumen: this is the prevailing kind in the Northumberland and Durham mines. 2. The cannel coal, called parrot coal in Scotland, contains about twenty per cent. of bitumen: this coal occurs in Lancashire also. 3. The stone coal, likewise known under many other names, contains little or no bitumen: this is the ordinary coal of the Staffordshire and Scotch collieries. The coal seams, together with their alternating strata, called the *coal-measures*, usually lie on beds of millstone grit and shale (hard coarse-grained sandstone and slate-clay), which sometimes exceed 120 fathoms in thickness. Under this series is the mountain or carboniferous limestone, an assemblage of calcareous strata, of variable thickness, sometimes exceeding 900 feet. This limestone is frequently characterized by caverns* and fissures. The carboniferous limestone rests on a bed of old red sandstone, varying in thickness from 200 to 2000 feet. These four different series of strata are usually comprehended under the term 'coal formation.' Though in general the coal-measures lie above the three beds just enumerated, these beds do not form an essential part of the coal formation; for sometimes the coal-measures occur without these intermediate series, and repose immediately on the transition rock: such is the case in the coal-fields of Coalbrook Dale and of Dudley.

A general resemblance in structure appears in all the English coal-fields, but still with considerable local varieties. The phenomena by which dykes or faults are produced have sometimes uplifted the strata on one side of the dyke many fathoms above those on the other side, and occasioned irregularities extremely perplexing to the miner. These dykes are fissures which traverse the strata, often extending several miles, and penetrating generally to an unknown depth. These fissures are usually filled with clay, with the debris of the dislocated strata, or sometimes by basaltic rocks

COAL-DISTRICT NORTH OF THE TRENT.—This great coal formation encircles the whole Penine chain on the east, south, and north; not however in one uninterrupted line, but in a series of detached coal-fields. 1. The coal-field of Northumberland and Durham. 2. Some small detached coal-fields in the North of Yorkshire. 3. The coal-field of South Yorkshire, Nottingham, and Derby. 4. The coal-field of North Stafford. 5. The South Lancashire coal-field. 6. The North Lancashire coal-field. 7. The Whitehaven coal-field.

1. *The Coal-field of Northumberland and Durham* commences near the mouth of the river Coquet on the north, and extends nearly to the Tees on the south. As far as Shields the sea is its boundary on the east; from that point it leaves a margin of a few miles between it and the sea, and extends about ten miles west from Newcastle. Its greatest length is fifty-eight miles, and its greatest breadth about twenty-four. The coal-measures of this field rest on the series of strata of the millstone grit and shale, and are in part under the magnesian limestone, the northernmost point of which is near the mouth of the Tyne. The beds of which this coal formation is composed dip towards the east and crop out towards the west, so that a section of them gives the idea of a form of a boat. In consequence of this disposition, the beds of coal in some places appear at the surface, while in the middle of the basin they are at great depths. At Yarrow, about five miles from the mouth of the Tyne, one of the thickest beds, called the High Main, is 960 feet deep, and rises on all sides; the dip of the strata averages one inch in twenty, but this is not uniform throughout; and therefore that bed does not rise to the surface at equal distances around Yarrow. The beds of the coal-measures are eighty-two in number, and consist of alternating beds of coal, sandstone, and slate-clay; making an aggregate thickness of 1620 feet, which varies however in different parts. The irregularities of the surface do not affect the dip or inclination of the strata; so that when a valley intervenes, they are found in the sides of the opposite hills at the same levels as if the respective strata had once been continuous. It is difficult to determine the exact number of beds of coal, in consequence of the different depths at which the same bed occurs, the numerous faults, and the varying thickness of the beds of coal and other strata. These strata occasionally enlarge and contract so much, that it is only by extensive observation that the identity of the seams can be ascertained. Dr. Thomson supposes the whole number of beds of coal in this field to be twenty-five; Messrs. Conybeare and Phillips state that forty beds of coal have been seen; a considerable number however of these are very thin. The two most important beds are those distinguished by the names of High Main and Low Main. The thickness of the first is six feet, and of the second six feet six inches. The Low Main is about sixty fathoms below the High Main. Eight other beds of coal occur between these: one called Bensham is four feet thick, and another called Coal Yard is three feet thick. Seven beds of coal have been observed under the Low Main, some of which are of considerable thickness, but of an inferior quality. The aggregate thickness of the whole number of seams is about forty-four feet; but there are eleven beds not workable, the thickness of some of them being only a few inches. Five others amount together to only six feet. Making proper deductions for these, it may be considered that the available beds amount to thirty feet in thickness. The different strata which occur in the G. Pit, Wall's End colliery, are given in the Parliamentary Report on Accidents in Mines, 1835. The space which it would occupy prevents our inserting this tabular view of the strata.

The whole surface of the coal-field is calculated by Dr. Thomson at 180 square miles, on the assumption that its length is twenty-three miles, and mean breadth eight. But according to the latest geological maps, these dimensions appear very far below the actual length and breadth, and it is perhaps nearer the truth to estimate the area at double that number of square miles. The greatest number of mines are on both sides of the Tyne, and not far from its banks. There are several in the northern part of the field, and many about five miles south of the Tyne, about midway between Newcastle and Durham.

The number of dykes or faults which traverse this field is very considerable. They appear to run in all directions. The most remarkable, called the Great Dyke, or 90-fathom dyke, has received the latter name because the beds on the north side of it have been thrown down 90 fathoms. Its direction is N.N.E. and S.S.W. It enters the sea a little to the south of Hartley, or about three miles north of Shields, and running westward crosses the Tyne at Lemington, about four miles west of Newcastle bridge. In some places it is only a few inches wide, but in Montagu colliery it is 22 yards wide, and is filled with hard and soft sandstone. From the southern side of this dyke two others branch off, one to the S.E. and the other to the S.W The latter, called from its breadth the 70-yard dyke, is also filled with hard and soft sandstone. This dyke intersects the upper or Beaumont seam of coal, but does not alter the level on either side. The thickness of the seam however decreases, beginning at the distance of 15 or 16 yards from the dyke; and the coal first becomes sooty, and at length assumes the appearance of coke. The south-eastern branch is only 20 yards in breadth. Another dyke, which passes through Coaley Hill, about four miles west of Newcastle, is about 24 feet wide. It is filled with basalt in detached masses, which are coated with yellow ochre; a thin layer of indurated clay is interposed between the sides of the fissure and the basalt. The upper seam of coal is here about 35 feet from the surface, and where it is in contact with the dyke is completely charred. Another dyke, which crosses the Tyne at Walker, and traverses the Walker colliery, does not alter the level of the strata, but on each side of it the coal is converted into coke, which on one side in some places was found to be 18 feet thick, and on the opposite side only about 9 feet. (Conybeare and Phillips, p. 447.) At Walbottle Dean, 5¼ miles west of Newcastle, a double vein of basalt crosses the ravine in a diagonal direction, passing nearly due east and west; it underlies at an angle of 78 degrees, and cuts the coal strata without altering their dip, but the seam of coal is charred. A dyke, called the Cockfield Dyke, 17 feet wide, throws up the coal-measures on the south 18 feet. The Low Main coal, contiguous to the basalt, is only 9 inches thick, but enlarges to 6 feet at the distance of 150 feet from it; the coal contiguous to the dyke is reduced to a cinder. The dykes, if not large, are locally called *troubles*, *slips*, or *hitches*. These minor faults are numerous and extensive, and are a perpetual source of difficulty and expense to the coal-owner by disturbing the level of the strata and by the disengagement of carburetted hydrogen gas. They are not however without their use, being often filled with a tenacious water-proof clay, by which numerous springs are dammed up and brought to the surface. The faults which depress the strata have kept valuable seams within the basin, which would otherwise have cropped out and have been lost.

---

* The Derbyshire caverns are in this limestone.

The coal-field of Northumberland and Durham supplies an enormous quantity of coal. Besides being consumed in its own district, London depends nearly altogether on it, as well as all the southern coast counties, with the exception of Cornwall. It is consumed along the eastern coast, including all the eastern counties as far west as Hull, Boston, Peterborough, Bedford, and Windsor. Shields, Stockton, Seaham, and Sunderland, are the ports from which the coal is shipped: the Tyne vessels, being the larger, are laden for the London market; those of the Wear, which are much smaller, sail to the small rivers and harbours along the coast, and carry coal as far west as Plymouth. An inquiry as to the probable duration of this supply is one of no small interest. Dr. Thomson calculates that this coal-field may fairly be expected to yield coal for 1000 years, at the annual consumption of two millions of chaldrons; but as we have no data by which to discover how much coal has been already consumed, we cannot tell how much of these 1000 years has already elapsed. Besides this, Dr. Thomson has taken the average annual consumption much too low for the present time. The coals shipped from the Tyne, the Wear, and the Tees, in 1835, amounted to 4,368,144 tons. The quantity of waste coal is estimated at one-third of the whole. Without therefore taking into account the consumption of the immediate district, the annual quantity of coal taken from the mines is more than 6,552,216 tons.

On the other hand it appears that in this calculation the area of the coal-field is very much under-estimated, being taken at 180 square miles. Professor Buckland, in his examination before the House of Commons, limits the period of supply at the present rate of consumption to about 400 years. Mr. Baily, in his Survey of Durham, states the period for the exhaustion of the coal to be about 200 years hence. Some proprietors of the coal-mines, when examined before the House of Commons, in 1830, extended the period of exhaustion to 1727 years. They assumed that there are 837 square miles of coal strata in this field, and that only 105 miles had been worked out. The small coal taken out of the pits is not considered worth shipment; large quantities of it are therefore often piled up near the mouths of the pits. These masses of coal are frequently set on fire, and burn for several years. Dr. Thomson describes two of these immense fires which were burning in 1814. About three miles to the north of Newcastle and three miles off the road from Berwick, on the left hand, 'one has been burning these eight years. The heap of coal is said to cover twelve acres. The other, on the right hand, is nearer the road and therefore appears more bright: it has been burning these three or four years (1814).' Of late years many more manufactories have been established in this district, by which a great quantity of the small coal is consumed.

Besides this coal-field there is another coal formation in the northern counties, which is minutely described by Dr. Thomson in the 'Annals of Philosophy,' November, 1814, under the name of the Independent Coal Formation. This tract terminates westward at Cross Fell, in Cumberland, is supposed to occupy the whole of Durham, and constitutes the whole of that part of Northumberland east of the Cheviots, exclusive of the coal-field already described. The different strata of this coal formation amount to about 147. The coal-measures here differ from those we have just noticed, in having limestone as well as sandstone and slate-clay alternating with the beds of coal; the coal worked in this formation is slate-coal, and is considered inferior in quality to the Newcastle coal. There are several collieries, but the coal is only employed for home consumption. The lowest bed of these measures crops out near Cross Fell. The coal of which it is composed, provincially called crow-coal, falls into powder when exposed to the air, and cannot be burnt by itself. The poorer class make it up into balls with clay, and use it for fuel. This bed is 387 fathoms below the lowest of the Newcastle beds. (*Ann. of Phil.*, vol. iv.) There are numerous lead mines in this tract.

2. *Detached Coal-fields in the North of Yorkshire.*—These are very limited in extent, being small insulated coal basins, lying in hollows in the gritstone. They occur near Middleham, Leyburne, Thorpefell, near Burnsell, and as far west as Kettlewell. The seam is seldom more than twenty inches thick. At Thedswell Moor the lowest seam is one yard, but the stratum diminishes and vanishes at the edges. Messrs. Conybeare and Phillips doubt whether these beds should not be referred to the thin coal seams subordinate to the millstone grit series rather than to the principal coal-measures.

Coal is wrought in some parts of the great carboniferous chain extending from Penigent to Kirkby Stephen. Here the great 'Craven fault' occurs, described by Professor Sedgwick ('On the Carboniferous Chain from Penigent to Kirkby Stephen,' *Geol. Trans.*, vol. iv. series 2) as ranging along the line of junction of the central chain with the skirts of the Cumbrian system, passing along the south flank of Casterton Low Fell, up Barbondale, thence across the valley of Dent through the upper part of the valley of Sedbergh, and along the flanks of Bowe Fell, and Wildboar Fell, to the ridge which flanks Ravenstone Dale. Throughout the whole of this line there are enormous and most complex dislocations, which affect the strata of the coal formation and produce other phenomena. Only one of the coal strata in the lowest part of the coal-measures is sufficiently valuable to be worked; it varies from eighteen inches to nearly four feet in thickness. At Turna Fell, near Hawes, in Yorkshire, and at Tan Hill, near the highest part of the road from Brough to Argengarthdale, this coal is extensively worked, and is of good quality. The same seam is found near Kirkby Stephen. Horizontal drifts have been carried into this bed near the top of Penigent, of Whernside, and of Great Colm; but in these parts it is of bad quality and not fit for domestic use, being mixed with ferruginous and pyritous shale. This coal varies in thickness from a mere trace to two feet. It was once worked to some extent on the south side of the valley of Dent, by means of horizontal drifts under Great Colm. It was only a few inches in thickness, but said to be of so good a quality as to be in great request. About 70 or 80 years ago it was sent on pack-horses from this place as far as Kendal, for the use of blacksmiths' forges, &c. Kendal has long been supplied with fuel from the Lancashire coal-fields; but this fact, of comparatively so recent a date, strongly illustrates the astonishing progress we have made in our modes of internal communication.

At the Barbon coal-pit in Westmoreland, a coal-bed of this series is likewise wrought; the lower part of it is however so impure as to be unfit for ordinary purposes, and is chiefly consumed in lime-works. The following is a section of the strata as occurring in the Barbon colliery:—

		feet.	in.
1	Alluvial soil	52	6
2	Plate (calcareous shale) . . .	1	6
3	Limestone, the 4th or Mosdale Moor limestone of the great section .	27	0
4	Gritstone	27	0
5	Alternations of shale and gritstone .	12	0
6	Shale	30	0
7	Crow limestone	2	0
8	Plate with a 3-inch crow-coal . .	1	6
9	Gritstone	27	0
10	Coal	1	2

The strata of the coal are in general much less regularly continuous than the strata of limestone. This however is not always the case. Some of the thin bands of coal here appear to continue with astonishing regularity. The following example is quoted from Professor Sedgwick. 'At Cross Pits, in the valley of Dent, the coal seam under the 12-fathom limestone is divided, by a band of clay half an inch thick, into two parts, with distinct mineral characters; and the same coal seam, with exactly the same subdivisions, has been found in the mountain on the opposite side of the valley at the distance of three or four miles measured in a straight line. This seems to prove that a bed not more than a fraction of an inch thick was originally continuous throughout an area probably several miles in diameter.' (*Geol. Trans.* vol. iv. sec. 2, p. 101.)

3. *Coal-field of South Yorkshire, Nottingham, and Derbyshire.*—This extensive field, which in character is closely allied to that of Newcastle, is considered by some geologists as a re-emergence of the same strata from beneath the covering of magnesian limestone under which it is concealed through the intervening space. This coal-field occupies an area extending north and south from a little to the N.E. of Leeds nearly to Derby, a distance of more than sixty-five miles; its greatest width, 23 miles, is on the north, reaching nearly as far as Halifax to the west. On the south it extends towards the east to Nottingham, and is here about 12 miles wide; but in some parts it is much narrower. The strata of these coal-measures range in the same manner as in the Northumberland coal-field, from north to south, dip to the east and rise to the west and N.W., in which directions the lowest measures at length crop out against the rocks of the millstone-grit series, which constitute the higher ridges of the Penine chain. The strata of this coal formation are very numerous. There are twenty beds of gritstone at the least, some of great thickness. Most of these beds consist of grains of semi-transparent silex united by an argillaceous cement; the lowest of these beds is termed the millstone grit, beneath which no workable coal is found. Besides these gritstone beds there are numerous strata of shale (slate-clay), bind (indurated loam), and clunch (indurated clay), alternating with several beds of coal of different thickness and value. A hard argillaceous rock called crow-stone forms in some places the floor of the coal beds, and is supposed to be a variety of the clunch still more highly indurated. The numerous faults in this coal-field render it extremely difficult to ascertain the exact number and order of the coal beds. Mr. Bakewell (p. 384) states their number at thirty, varying from six inches to eleven feet, and the total thickness of coal at twenty-six yards. This however he considers as only an approximation. Three varieties of coal occur in these measures: *hard*, or stone, which burns to a white ash; *soft*, or bright, which burns to a white ash; *caking*, or crozling, which usually burns to a red ash. The first is esteemed the best, and is in much greater demand than the others. The thickest bed is worked near Barnsby. In a pit near Middleton, the property of the Reverend Ralph Henry Brambling, three seams are being worked; one at the depth of about forty to seventy yards from the surface, another thirty-eight yards lower, and the deepest from twenty-eight to thirty-two yards deeper, making the whole depth from one hundred and ten to one hundred and forty yards. The upper seam is about two feet eight inches thick, the middle seam from two feet ten inches to three feet four inches, and the lower one from four feet six inches to five feet.

The strata of this field, according to Mr. Farey, are traversed by an immense fault commencing from Allestry, in the south, and running in a zigzag direction through the south and east part of the field; the rise of the strata is said to be much more rapid on the western than the eastern side of the fault. Besides this great fault there are many others which traverse the field in various directions, and create an inextricable confusion by the rise and fall of the different strata, rendering it almost impossible to trace distinctly the continuation of each bed. This coal-field supplies the coal for the important manufactures which surround it, and also, by means of inland navigation, the midland counties south and east of Derbyshire.

A little to the west of the coal-field already described, coal has been found in two places about half way between Ashborne and Derby, but it has not been worked.

4. *Coal-fields of North Stafford.*—There are two detached coal-fields: the one situated on the N.E. of Newcastle-under-Lyme, distinguished as the Pottery coal-field; the other at Cheadle, to the east of the first. The form of the Pottery coal-field is triangular. Its vertex is near Congleton, from which point the sides diverge to the S.S.E. and S.S.W., running in each direction about ten miles; the base is estimated at about seven miles: Newcastle is nearly in the centre of the base. The strata dip from the two sides to the centre of the area. On the eastern side the inclination westward is estimated at one foot in four; on the other side it is still more rapid. Between Burslem and its eastern limit, nearly in the centre of the coal-field, it has been ascertained that there are thirty-two beds of coal of various thickness, generally from about three to ten feet each; but the strata are in general much dislocated in this field.

In the principal mines in this district coal is found at various depths, from fifty to three hundred yards and more; there has been a mine worked at the depth of more than four hundred yards. Some seams only twenty inches thick have occasionally been worked, but they are seldom worked under three or four feet thickness.

The Cheadle coal-field is an insulated basin surrounded by and reposing upon millstone grit; it is about five miles long and three miles broad, and is of little importance.

5. *The Manchester or South-Lancashire Coal-field* is separated from that of South Yorkshire and Derbyshire by the range of lofty hills extending from near Colne to Blackstone Edge, and thence to Ax Edge in Derbyshire. It commences near the western side of this range in the north-west of Derbyshire, and continues thence to the south-western part of Lancashire, forming an area somewhat in the shape of a crescent, having Manchester nearly in the centre. The chord or span between the opposite horns is about forty miles. It runs nearly due north from Macclesfield to a few miles beyond Rochdale, a distance of thirty miles; the part between Macclesfield and Manchester is however very narrow, being in some places not two miles in width. From Rochdale it extends westward to Bolton and Chorley, south-west to Leigh and Prescot, north-west to Preston, and north to Colne. Viewing it as a whole, the strata rise towards the exterior edge of this crescent-shaped coal-field, along which the strata of millstone grit, on which they repose, crop out from beneath them, and dip towards its inner edge, where they are covered by the superior strata of the newer sandstone formation, which contain occasionally beds of calcareo-magnesian conglomerate. Great disturbances have however interrupted the regularity of this arrangement, and caused divisions of the coal-measures which render it difficult to trace out the exact dimensions of the field. At Disley, in Cheshire, it 'bifurcates' into two branches, having an intermediate ridge or 'saddle of millstone grit, the eastern branch forming a trough, of which the strata crop out on both sides against the millstone grit.' This part of the field is a long narrow strip joined to the main field at Disley, and extending thence southwards fifteen miles to near Mearbrooke in Staffordshire. The strata of the western branch of this bifurcation, extending from Disley to Macclesfield, dip again to the west, but not at so great an angle as they rise, on the east side of the intermediate ridge. In other parts of the coal-field great faults occur, but it has not been sufficiently investigated by the geologist for them to be distinctly traced. Mr. Bakewell has investigated a small portion, which he distinguishes as the coal-field of Bradford: the result of his observations is found in the second volume of the *Geological Transactions*. This tract is rather more than two miles long, and little more than one mile and a furlong wide. It is situated on the river Medlock, a short distance E.S.E. of Manchester. It is surrounded on every side, except the east, by the red sandstone which prevails in the environs of Manchester. Beds of limestone pass under this, and overlay the coal-measures, in which there are several beds of coal rising to the north, under an angle of 30°. One of these, near the centre of the field, is four feet in thickness. To the north of these inclined beds there is a considerable disturbance, and the direction of the beds becomes suddenly vertical. One of the vertical beds, together with its accompanying strata, bears so close a resemblance to the four-feet coal above mentioned, that there is no doubt of their identity, and that the vertical stratum was, before the dislocation which severed them took place, a continuation of the first. With these vertical beds the coal-measures terminate: on the north an interval of the red sandstone succeeds for about 1400 yards, when coal-beds again appear, rising as before towards the north. All this indicates considerable faults and subsidences, which however cannot be accurately traced at present. The coal from the Lancashire field supplies Manchester, Liverpool, and the surrounding district.

6. *The North Lancashire Coal-field* is one of little importance. It lies midway between Lancaster and Ingleton; it is about eight miles long and six miles wide, but it has never been thoroughly examined, and its strata cannot be distinctly stated.

7. *The Whitehaven Coal-field* is situated on the west coast of Cumberland, and extends from near Egremont, south of Whitehaven, to Allonby on the north.

Mr. Buddle, in his examination before the House of Commons, states that the thickest seam in this coal-field is nine feet; and in speaking of the Whitehaven colliery calls it 'the finest in England, both in point of thickness of the seams and in extent.' The shafts in the mines belonging to this field are usually very deep: there are several 100 fathoms and upwards. The Workington mines, in which the same seam is worked as in those of Whitehaven, go to a considerable extent under the sea, but not so far as the Whitehaven collieries.

Central Coal District.—Under this division are classed the coal-fields of Ashby-de-la-Zouch, of Warwickshire, and South Staffordshire.

1. *The Coal-field of Ashby-de-la-Zouch* is of a very irregular figure, and so much dislocated, that it rather forms two small basins than one continuous whole. The greatest length from north-west to south-east is about ten miles, the greatest breadth about eight miles. The eastern extremity of this area approaches almost close to the transition district of Charnwood Forest. This coal-field is described by Mr. Farey 'as one of the highly curious but perhaps not uncommon occurrences, in the red marl districts; a tract entirely surrounded by a fault, or a series of faults, which unite, seem lifted up through the red marl strata, and denudated, the coal strata having rapid dips in various directions, while the surrounding strata of red marl are horizontal, or as nearly so as may be.' Of the two portions of the field, one ranges by Ashby Wold, about three miles on the west of Ashby; the other by Cole Orton, about the same distance on the east.

The Ashby Wold portion ranges from Swepston, four miles south of Ashby, to Bretby in Derbyshire: the inclination of the strata is towards Ashby; but between the out-crop of the beds and that town another crop has been traced near Brothorpe, dipping in a contrary direction. More than twenty coal-works have been opened on this line. The lowest shaft sunk is to the depth of 246 yards. One of the seams is from 17 to 21 feet thick. This great thickness is caused, it is supposed, by the running together of two or more seams—a circumstance which is known to occur in the coal-fields of South Staffordshire. The eastern portion of this district commences about a mile and a half north-east of Ashby, and extends about six miles in length, running parallel to the larger portion. The strata dip to E.N.E. In the pits belonging to Sir George Beaumont two coal-beds, each a yard and a half thick, are worked. On Cole Orton Moor several coal-seams, which have been proved to lie above these, have been worked at the depth of 116 feet.

2. *The Warwickshire Coal-field* commences at Wyken and Sow, two villages about three miles east of Coventry, and continues in a north-west direction to Polesworth and Wareston, about five miles east of Tamworth, a distance of sixteen miles: its average breadth is about three miles. All the strata rise to the E.N.E., the inclination becoming greater towards the eastern edge of the field, where in many parts it makes an angle of more than 45° with the horizon: towards the west it decreases to about one foot in three, and lastly in five. The principal collieries are near the south of the field, at Griff and Bedworth. The depth of the first is 117 yards, and the principal seam three yards in thickness. The same seams are worked in the Bedworth mines, but there the first and second coal-seams of Griff run together and form a five-yard seam. The intermediate strata of shale which separate them at Griff are found in the eastern shaft to be thirty-three, and in the western twenty-five yards thick; but they gradually decrease as they proceed westwards, till at length they entirely vanish.

3. *South Staffordshire* or *Dudley Coal-field*, the principal in the central district, extends from Beverton, near Badgely, on the N.E., to near Stourbridge on the S.W. The greatest length is about twenty miles, and its greatest breadth, from Walsall to Wolverhampton, is about seven miles, but it is very irregular towards the south, being almost divided into two parts. The area from actual survey has been found to be about sixty square miles. The southern portion, extending from Stourbridge to Bilston, about seven or eight miles in length and four in breadth, has been fully investigated by Mr. Keirs, and described by him in Shaw's 'History of Staffordshire.' No satisfactory account of the northern portions of this field has hitherto been published; many coal seams, of eight, six, and four feet in thickness, are worked in it. The southern portion is of much more importance, as it contains seams from 30 to 45 feet in thickness. This enormous thickness is however not one continuous seam, but a number of seams, divided by layers of what the miners call band, which are very thin beds of clay-slate. The working of these thick seams is not so profitable as might be supposed. The pillars left standing in order to support the high roof are estimated at about one-third of the whole coal in the bed, and the small coal left in the mine is about equal to another third, so that only one-third of the whole is at present taken out of the mine.

In the coal-measures of this district there is an absence of the millstone grit, carboniferous limestone, and old red sandstone, which usually lie under the coal-measures. The coal-measures rest, in the Dudley Coal-field, on the transition rock at once, without any intermediate strata: this singularity is likewise observed in the Coalbrook Dale coal formation.

The coal district in South Staffordshire is traversed from N. W. to S. E. by apparently a line of hills, but they are not absolutely continuous, though they have a uniform general direction. On examination, the hills on the north and those on the south of Dudley are found to differ entirely in their character. The northern chain consists of highly inclined strata of limestone, against the sides of which all the coal-measures crop out at a considerable angle, but come nearer a horizontal position as they recede from these hills. The other chain of hills, on the S. of Dudley, are entirely composed of one mass of basalt and amygdaloid, and the coal-measures preserve their usual level in approaching the hills, not cropping out as they do upon the limestone chain. Two opinions are entertained with regard to these basalt elevations: 'they may be either the protruding edge of a vast basaltic dyke traversing the coal-field, or an overlying mass:' the latter is considered the more probable. The coal-measures on the south, near Stourbridge, appear to dip beneath the beds of the newer red sandstone formation: the beds of this and of the Warwickshire coal-field dipping in opposite directions under the super-strata give reason for supposing that they may extend continuously below this through the intervening space. The eastern side of the field, which extends a little beyond Walsall, is bounded by the same limestone with that of Dudley, and the coal-measures are observed again to crop out against it, thus lying in a basin between these two towns. That the coal-beds rise towards the north, and the upper ones crop out while others continue under the surface, is very satisfactorily shown by the comparison of the strata in different collieries. At Tividale the main coal is sixty and a half fathoms below the surface; at Bradley it is only twenty and a third; and the greater number of beds which cover the main coal at the former place have entirely disappeared before the main seam reaches Bradley; and farther to the north the main seam also crops out and disappears altogether. A very curious phenomenon takes place at Bloomfield Colliery, to the S. Bilston, thus described in the 'Geology of England,' p. 412. 'The two upper beds of the main coal, called the roof, floor, and top slipper, separate from the rest, and are distinguished by the name of the *flying reed.* This separation grows wider, and at Bradley Colliery amounts to twelve feet, four beds of shale (slate-clay), and ironstone, being interposed. These two upper beds crop out, while the rest of the main coal goes on to Bilston, and is only eight yards thick.'

This district supplies coals to the numerous iron-works in the immediate neighbourhood, and the manufactories of Birmingham and its vicinity; besides which, all the neighbouring counties, as far south as Reading and Gloucester, are supplied by means of inland navigation

The clay ironstone occurs in various beds, but is only wrought in two: one of these is the bed under the main coal, and is wrought for iron ore.

Many faults or dykes occur in this field; they are usually fissures in the beds, filled up with clay, and very frequently the levels of the different strata vary in consequence.

There is a great fault near Bilston, which causes the dip of the strata to be reversed, the beds on the south side dipping south, and on the north side dipping north: this is however an unusual circumstance.

Dr. Buckland has observed indications of coal near the Lickey Hill, a few miles south of this coal-field.

Western Coal Districts.—The coal-fields of this division are disposed around the transition district of North and South Wales. The north-western district includes the coal-fields of Anglesey and Flintshire, the western those of Shropshire, the south-western those of South Wales, of South Gloucester and Somerset, and of the Forest of Dean.

1. *Isle of Anglesey.*—At the distance of about six miles from the Menai Straits, and running nearly parallel to them, a remarkable valley stretches across the whole island. This valley opens on the north into Red Wharf Bay, and on the south into the æstuary of Maltraeth; it is flanked on both sides by parallel bands of carboniferous limestone, in the depression between which coal has been found, and it is thought probable that the coal-measures may extend through the whole line. Coal has been worked near the Maltraeth æstuary; and a few years since shafts were sunk in the neighbourhood of Trefdaeth. Successful trials have likewise been made at Pentreberen, about five miles north-east of the former pits: the beds are said to be of a tolerable thickness, and the coals of a good quality.

2. *Flintshire.*—The coal-field of this county extends north and south from Llanassa, near the western cape of the æstuary of the Dee, to near Oswestry, in Shropshire, forming an exterior belt co-extensive with the range of the mountain line from the north of the Clwyd. Where the carboniferous limestone is partially interrupted by the mountain of Selattyn the coal shales rest immediately on the transition slate, of which that mountain is composed. (Conybeare and Phillips, p. 419.) The greatest length of the district in which the coal-measures are found is about thirty miles, but it must by no means be understood that coal is worked throughout. At Oswestry there is a very small detached piece, not more than three miles long and half a mile broad; there is then an interval of some miles. Near Chirk another coal tract commences, and runs north for about five miles; then another interval occurs; and a little to the north of Wrexham the principal portion begins, and thence extends to the coast and forms a narrow belt along it to the termination at the west cape of the Dee. The beds dip from one yard in four to two in three, sink beneath the æstuary of the Dee, re-appear on its opposite side, and finally sink beneath the strata of the newer red sandstone. This position of the coal-measures has led to the conjecture that they are connected with the beds of the Lancashire coal-field. The coal formation here commences with the same strata as those of Derbyshire. The beds of coal vary in thickness from three quarters of a yard to five yards. In the Baggalt mines three seams are worked, varying from three feet and a half to seven feet. Common, cannel, and peacock coal are found.

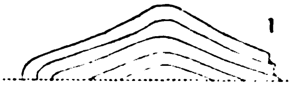
3. *The Coalbrook Dale Coal-field* rests on transition rock: it extends from Wombridge, in the parallel of Wellington, to Coal Port, on the Severn, a length of about six miles; its greatest breadth is about two miles. The coal-measures are composed of the usual alternating strata, which occur without much regularity, except that each bed of coal is always immediately covered by indurated or slaty clay, and not by sandstone. The strata are eighty-six in number. In Madely colliery a shaft is sunk 729 feet through all the beds. The first coal seam, which occurs at the depth of 102 feet, is very sulphureous, and not more than four inches thick; nine other beds of a similar nature, but rather thicker, occur between this and the depth of 396 feet. This coal is called 'stinking coal,' and is only employed in the burning of lime. The first seam of coal that is worked is 496 feet deep and five feet thick. Two other beds of coal occur, one ten inches and the other three feet thick, before the bed of 'big flint' sandstone, which is found at the depth of 576 feet: nine beds of coal occur, of the aggregate thickness of 16 feet, between the 'great flint' and the 'little flint' bed (an interval of 100 feet). Beneath the 'little flint' and the lowest bed of the whole formation, there is a sulphureous eight-inch coal. This account of the strata refers more particularly to the Madely colliery. The coal of this field is usually a mixture of slate-coal and pitch-coal.

West of the Coalbrook Dale field there are a few detached, narrow, and broken coal-fields in the plain of Shrewsbury, at the other side of the Wrekin.

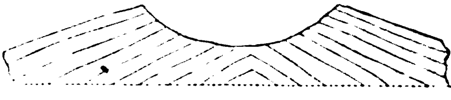
Several small coal-fields occur in the Brown Clee Hill and the Titterstone Clee Hill, which rise a few miles south of the Coalbrook Dale-field; the latter hill is about four miles south of the former. The coals in the Brown Clee Hill only lie in thin strata, while the principal stratum in the Titterstone Clee Hill is six feet thick. The coal-fields on the Titterstone Clee Hill are represented as six detached portions, or separate basins, cut asunder and rendered irregular by a vast basaltic dyke, more than 100 yards wide, which intersects the hill. These coal-measures are more interesting to the geologist than the miner.

On the east of these hills, and between them and the Severn, a coal-field extends from Dense Hill and Billingsley on the north, to the borders of Shropshire and Worcestershire on the south, a length of about eight miles, coal being worked in several points along this line. Coal is also worked near Over Arley, on the Severn, adjoining the tract on the west. Only a few miles from the Billingsley coal-field at Pensex, near the foot of the Abberley Hills, is 'a small patch (rather than field) of coal-measures,' and another similar piece about three miles to the west.

The South-Western Coal District comprehends the several coal-fields near the æstuary of the Severn and the Bristol Channel, including parts of the adjacent counties of Gloucester, Somerset, Monmouth, and Glamorgan. The various coal-fields distributed over this district are apparently insulated, yet they have several points of connection. 'They all rest on one common base of old red sandstone; they all appear to have been formed by similar agency, and at the same era, to have been subject at a later period to the same revolutions, and lastly to have been covered partially by similar overlying deposits.' (*Geol. Trans.*, vol. i., 2nd series.) Messrs. Buckland and Conybeare have found that the several basins in the coal formation are divided by lines (which they term '*anticlinal*') formed by the saddles of the strata or meetings at the surface of their vertical angles, on each side of which the strata dip in opposite directions.[*]



1



2

The coal-measures are thus surrounded by exterior bands of mountain limestone and old red sandstone, in the order of the outcrop of the subjacent beds. This district includes three principal coal basins, together with some smaller ones, adjacent to and closely connected with the two last. First, the South Welsh coal basin; second, that of South Gloucester and Somerset; third, that of the Forest of Dean.

1. *The Coal-field of South Wales* is upwards of 100 miles in length, and the average breadth in the counties of Monmouth, Glamorgan, Caermarthen, and part of Brecon, is from eighteen to twenty miles; it becomes much narrower in Pembrokeshire, being there only from three to five miles. This area extends from Pontypool on the east, to St. Bride's Bay on the west, and forms a vast basin of limestone, in which all the strata of coal and ironstone are deposited. The deepest part of the basin is between Neath and Llanelly: from a line ranging nearly east and west through Neath, all the strata rise on the south towards the south, and on the north towards the north, cropping out at the edges. The limestone crops out at the surface all round the coal, except where its continuity is interrupted by Swansea and Caermarthen Bays. The depths from the surface to the various strata depend upon local situations. The upper coal seam does not extend a mile either north or south beyond Neath, and not many miles in an east or west direction, and its utmost depth is not above fifty or sixty fathoms; the next stratum of coal and those likewise beneath, being deeper, crop out at greater distance from the centre, and so of the rest in proportion to their depth. The lowest bed is 700 fathoms deep at the

---

[*] 'Sometimes these lines follow the crests of the chains of hills (*fig.* 1); sometimes they are to be traced along the course of valleys (*fig.* 2): the hills in the latter case being formed not by the saddles of the strata, but by the denudments cutting through them.'

centre, and all the principal strata lie from 500 fathoms deep to this depth. But this district is intersected by deep valleys, which generally run in a north and south direction, intersecting the coal. By driving levels in the hills, the beds of coal are found without the labour and expense of sinking shafts; there are also many pits in the low valleys. (Martin, *Phil. Trans.* for 1806.) This basin contains twelve beds of coal, from 3 to 9 feet thick, making an aggregate of 70½ feet; and there are eleven more, from 18 inches to 3 feet, together equal to 24½ feet; the whole thickness is therefore 95 feet. A number of smaller seams likewise occur. On the south side of the basin, from Pontypool to Caermarthen Bay, the coal is principally of a bituminous nature; on the north-east it is a coking coal; on the north-west, stone coal. Great faults occur in this field, which traverse it generally in a north and south direction, and throw the strata out of their level 40, 60, 80, or 100 fathoms. These dislocations are not often shown on the surface. A principal fault occurs at Cribbath, where the strata of limestone stand erect: another of considerable magnitude lies between Ystradvellte and Penderryn. These dykes are usually filled with clay, but one of some magnitude has been observed near Swansea, which is many fathoms wide, and filled with fragments of the disrupted strata, the level of which differs by more than 240 feet. The rich ironstone of this basin supplies extensive iron-works in the neighbourhood. The principal beds of ironstone occur in the lower part of the coal-measures; the most valuable bed is found beneath the lowest coal. The strata of this coal formation dip much more rapidly on the south than on the north; on the south they make an angle of 45° with the horizon, and on the north dipping only 10°. The coal from the South Wales basin supplies the whole of Wales with the exception of the more northern counties, the whole of Cornwall, and the western half of Devonshire.

2. *South Gloucester and Somerset Basin.*—This basin occupies an irregular triangular space, bounded on the south by the Mendip Hills, which are a high range of mountain limestone resting on an arch of old red sandstone. The vertex of the triangle is on the north, at the village of Tortworth in Gloucestershire: the western side from the Mendips to the vertex is formed by three insulated masses of high land, separated by narrow intervals, the widest of which is less than three miles. Near Tortworth the range extending from Almondsbury is deflected suddenly to the south, and this may be considered the north-eastern frontier of the basin; it may also be traced through Wickwar to Sodbury. The south-eastern limit, from Sodbury to near Mells, the eastern extremity of the Mendips, is mostly concealed by overlying deposits. Partial denudations occur at Lansdown, near Wick Rock, where the limestone can be traced in the valleys dipping towards the centre of the coal basin. From Lansdown to the Mendips the continuity of the basin can be well ascertained, the coal-measures being uncovered in some of the valleys in which the principal collieries are situated. In other places shafts have been sunk through the overlying horizontal deposits, beneath which the coal is worked. The greatest length of this area is 25 miles: the width, from the collieries near Bath to those of Bedminster near Bristol on the west, is about 11 miles. In this district there is much local irregularity, and the stratification of the coal-measures is so deranged that they have very different and varying levels. In some parts the beds are denuded, in others concealed by the more recent horizontal deposits, and thus the whole basin is divided into several detached coal-fields.

The uncovered areas are distinguished by Messrs. Buckland and Conybeare ('Observations on the South-west Coal District of England,' *Geol. Trans.*, 1st vol., 2nd series) into the northern, the central, the southern, the eastern, and the western coal-tracts. The northern is the most extensive and elevated: its greatest length, from the vertex of the basin near Tortworth to the village of Brislington on the left bank of the Avon near Bristol, is 12 miles; its greatest breadth from east to west is nearly four miles. The collieries of Iron Acton, Sodbury, and Kingswood, are in this coal-tract. Along the northern limits of the basin, from Sodbury to Cromehall and Titherington, the coal-measures are exposed in immediate contact with the limestone; on the western, southern, and great part of the eastern border of the tract they are skirted by hills of red marl capped by lias. At Pucklechurch shafts are sunk to the coal through both the latter formations.

The central tract, which begins on the south of Dundry Hill, is divided into two parts by a narrow valley; the northern portion, about six miles in length, extends from Burnet on the north-east to Knowl-hill, near Stanton Drew, on the south-west; near Pensford it is about two miles in breadth. The southern division, extending from Temple Cloud on the west to between High Littleton and Timsbury on the east, is about three miles in length. To the south-east of this central coal-tract the coal-measures are entirely concealed by superjacent deposits through a distance of six miles. Throughout this space however many shafts are sunk, some through the red marl of the valleys, and some through the lias which occurs on higher ground. There are several of the latter description in the parishes of Timsbury and Poulton; but the deepest is on Clan Down near Radstock, which is sunk 200 fathoms before its horizontal adits are driven. Another shaft, beginning in the oolite, is sunk on the edge of the same Down near Paulton, but it is not so deep as the former, since here there is a rise in the strata, and the coal seams are in consequence much nearer the surface. On the ascent of the hill above Chilcompton the coal-measures are again exposed to the extent of about an acre.

The southern coal-tract commences near the point where the road between Bath and Shepton Mallet crosses the Nettlebridge stream, and ends between Vobster and Mells; its greatest length is six miles, and greatest breadth two and a half miles. The coal-measures of the eastern coal-tract are laid open in the vale of the Buoyd at Wick and Upton, both in Gloucestershire; they are likewise exposed at Newton St. Leo, on the left bank of the Avon below Bath, dipping towards the interior of the basin. Several seams are worked at Upton and Newton. The western coal-tract lies at the south-east of Leigh Down, near Bristol. Beds of red marl form the upper strata in the shafts of all the coal-pits of this tract between Long Ashton and Bedminster. The coal-field of Nailsea, lying more to the west, is a continuation of this tract.

A great undulation in the strata of the coal-measures which form the coal-basin of Somersetshire and the south of Gloucestershire alters the apparent position of the seams so much that it is very difficult to ascertain the identity of each throughout the various collieries. The local names of the several seams also tend to confuse the geologist.

The chain of hills which limits the western boundary of this coal district presents remarkable anomalies between Clevedon and Portbury, along its northern escarpment. A great fault ranging along the edge effects a very considerable subsidence of the strata. In consequence of this 'the coal-measures, depressed to the level of the old red sandstone, appear to occupy its place, and seem to dip beneath the mountain limestone, on which, in fact, they repose.' (*Geol. Trans.*, vol. iv., 2nd series.)

The following are the principal subdivisions of the coal-measures in this basin, beginning with the highest. The upper coal shale; the Pennant grit (sandstone); the lower coal shale; and the millstone grit. We refer the reader to the Memoir already quoted for a minute description of the various sections of this coal basin.

In the Bedminster colliery on the S.W. of Bristol, there are three seams of good bituminous coal: the deepest and uppermost are wrought; the former is four feet three inches, the latter two feet and a half to three feet thick; the middle seam is only one foot. The interval between the two principal seams is twenty-three fathoms; the lowest shaft sunk is 127 fathoms deep. These beds are obviously referrible to the lower coal shale. Works were established at Cromhall, a few miles north of Acton, about forty-five years ago, but were soon abandoned, in consequence, it is supposed, of the numerous derangements of the strata. They were again resumed, but not very profitably. The coal differed extremely in thickness in different places, varying from thirty to six inches; while in some parts no coal at all was to be seen. It never retained a regular thickness for many yards together, and in some places it diminished gradually in the line of the dip until it disappeared altogether.

The following is a section of the Cromhall colliery, as given in Mr. Weaver's 'Geological Observations on parts of Gloucestershire and Somersetshire,' *Geol. Trans*, vol. i. series 2:—

	yds.	ft.	in.
Soil and clay	2	0	0
Gritstone or sandstone	23	0	0
Clunchy bind, or indurated slate-clay	1	0	0
Coal, bituminous, very binding, yielding only small coal	0	2	3
Stony clunch, or sandy indurated clay	2	0	0
Rock or sandstone, partly compact and quartzy	15	0	0
Duns, or slate-clay	2	2	3
Black duns, being the immediate roof (very tender), or bituminous shale	0	0	9
Coal, bituminous, yielding large coal 16 inches, small coal 14 inches	0	2	6
	47	1	9

The floor consists of clunch, more or less stony; that is, indurated clay, more or less sandy.

In the meridian of Pitcot, situated a little to the N.E. of Nettlebridge, all the strata are vertical: a perpendicular shaft is there sunk to the depth of eighty fathoms in one bed of coal.

The total number of mines worked in this district is probably less than it was formerly, but the whole produce is certainly much greater, owing to improved methods in working. The seams of coal are very thin in comparison with those which are worked in the principal coal-fields of England, and in most of those would be rejected as not worth the working. The aggregate thickness of the seams worked in any single coal-pit scarcely exceeds one of the ordinary seams in the principal district. However, most of the old pits might again be worked to advantage by the present improved methods, and much of the area is still untouched, and ready for future speculation.

3. *The Forest of Dean Coal-basin* occupies an irregular elliptical area, circumscribed by the triangle formed by the Wye, the Severn, and the road from Gloucester to Ross; the largest diameter from N.N.E. to S.S.W. is about ten, the shorter about six miles. All the strata dip uniformly towards the centre of the basin. The whole of this coal tract, together with the high land that surrounds it, constitutes a mountain group, the average height of which above the level of the sea is about 900 feet. The aggregate thickness of the whole strata of the coal-measures is, according to Mr. Mushet, 500 fathoms; he divides the different strata into seven series, in which there are 27 beds of coal.

On the north of the Forest of Dean basin, and at the distance of a few miles, is the Newent coal-field, a very small tract surrounded and concealed by overlying strata of the newer red sandstone. This field has not been sufficiently explored to enable us to give an accurate account of it.

This description of the coal-fields of England contains sufficient examples both of the general position and distribution of the coal-beds, and of the variations to which they have been subjected, to give the reader a pretty complete view of the subject. Many matters of detail however, and some of the highest interest, are necessarily omitted in such a rapid sketch.

Scotch Coal-Fields.—Several small coal-fields occur in Dumfriesshire, forming narrow basins in the valleys of the great southern transition chain of Scotland. In the valley of the Nith, in the parishes of Sanquhar and Kirkconnel, there is one of these coal-basins, about seven miles in length, and two and a half in breadth. Three seams of workable coal have been discovered, averaging in thickness from three to four feet and a half. The range of the seams is in the direction of the Nith; the measures are disturbed by a dyke running north and south, by which the strata are much depressed on the east side. In the parish of Canobie, adjoining Cumberland, coal is worked in two pits: the principal seam is five feet ten inches thick.

The principal coal-district of Scotland occupies the tract which forms the great central lowland of Scotland, and lies between the great transition chain on the south, and the still loftier primitive mountains of the Highlands on the north. 'The whole of this wide tract is occupied by the coal-measures, the carboniferous limestone, and the old red sandstone, associated in every possible manner with vast accumulations of every variety of trap.' (Conyb. and Phil.)

To begin with the most eastern county in this tract in which coal is found: in the parish of Dunbar, on the east coast of Haddington, there are indications of coal, but no seams have yet been found of sufficient thickness for working. In the parish of Ormiston, in the west of the same county, coal is found in abundance; there are three workable seams of coal, varying from twenty-eight to forty-three inches in thickness, and the coal is of good quality.

Coal occurs in Fifeshire, on the north side of the Forth, but it is not at present much wrought. There are mines in the parish of Dysart, where coals were first raised in Scotland more than 350 years ago. There are fourteen beds of coal, three of which are now being worked; they are of the respective thicknesses of five, eight, and five feet. The pits are about sixty or seventy fathoms in depth.

Coal is wrought in several places in Mid Lothian.

In Lanark the coal-fields are numerous and extensive. The Wilsontown coal-basin and the Climpy basin both occur in the parish of Carnwath; the latter is on the west side of the first, the crop of the one nearly approaching the other. There are several seams of coal in these basins. The main coal, or lowest, is called the four-feet coal; another seam is about two feet in thickness. The accompanying strata are sandstone, varying in composition and hardness; bituminous shale, slate-clay, and thin beds of ironstone alternate with the coal. Several small faults, or hitches, as they are here called, traverse the field. On the S.W. part of the field, the main coal is generally fourteen feet below the crow coal, which is the next superior bed; on the N.E. the space between the same beds is only about two feet. These basins form part of the great coal-basin of the Clyde, which extends on both sides of that river, and the centre of which is near Dalziel. On the same side of the river, in the parish of Monkland, there are many collieries, in which the thickest bed of coal is nine feet, and it is of good quality. On the left bank of the river coal is wrought in several places. Five mines are worked in the parish of Rutherglen, and others in the adjoining parish of Cambuslang. There are several also in Hamilton, Stonehouse, and Douglass. Throughout this district seven seams of coal are usually found within 415 feet of the surface; five of these seams are of sufficient thickness and good quality to be wrought. The following shows the situation and thickness of the seams of coal in the pits in the parish of Cambuslang:—

	feet.	in.
Upper soil (earth and clay) from 20 to	30	0
Argillaceous white freestone	20	0
Shale, with vegetable impressions, from 30 ft. to 40 ft.	35	0
1st seam, soft coal	4	6
Interval (hard freestone, &c.)	26	6
2nd seam, soft coal	3	6
Interval (shale)	63	6
3rd seam, shaft coal	5	0
Interval {shale, 20 feet hard ironstone, from 6 to 18 in. shale and freestone}	65	2
4th seam, soft coal	6	0
Interval {shale freestone}	83	0
5th seam, soft coal	3	0
Interval {ironstone shale}	10	0
6th seam, hard coal, good for iron-works, forges, &c.	3	6
Interval (shale)	1	6
7th seam, soft coal	1	6
Till, &c., with thin seams of coal	84	0
	445	8

The thickness of the coal and of the freestone varies considerably in different parts, and the numbers here given must be taken only as an approximation. The strata are frequently deranged by faults, several of which run from east to west. In their general arrangement the strata usually run nearly parallel to each other, although they have always a considerable angle of elevation, and uniformly dip towards the Clyde. A great fault occurs between Hamilton and Quarter, and none of the principal seams are wrought for some miles north of this spot, the coal-beds being sunk nearly 100 fathoms lower than those out of the fault. The main seam worked at Quarter is five feet six inches thick, and consists of four distinct varieties of coal.

This coal-basin of the Clyde extends into Renfrew, where there are many collieries. Coal is wrought in the parish of Eastwood, in that county, in several seams of various thickness; but none exceed two feet six inches. The whole are of good quality. Five of them are wrought in pits varying in depth from ten to forty fathoms. The coal measures here consist of the usual series of freestone, shale, &c., dipping generally to the S.W. This coal formation partly surrounds the loch of Castle Semple, and continues without interruption into Ayrshire, around Kilbirnie Loch, and onward to Ardrossan. Coal occurs in different places in Dumbarton, where, among other parishes, it is wrought in Easter Kilpatrick. It is also found abundantly in Stirlingshire, along the southern base of the Lennox hills. Coal likewise occurs throughout Linlithgow, and is worked extensively in that county; it is likewise found in Clackmannan, and in the south of the counties of Perth and Kinross.

Irish Coal-Fields.—Mr. Griffiths, in his 'Report on the Leinster Coal District,' gives an excellent summary of the Irish coal-fields, from which what follows is taken. 'If we except the Leinster district, my knowledge of the coal-fields of Ireland is as yet very limited: and though each in its turn will form the subject of a separate report, I think it right to draw attention to them in this place, by giving such general information as I possess respecting their situation and circumstances. Coal has been discovered in more or less quantity in seventeen counties* of Ireland; but I believe the island contains but four principal coal-districts, viz., the Leinster, the Munster, the Connaught, and the Ulster. The two former contain carbonaceous or stone-coal, and the latter bituminous or blazing coal.

'The Leinster coal-district is situated in the counties of Kilkenny, Queen's county, and county of Carlow. It also extends a short distance into the county of Tipperary, as far as Killenaule. This is the principal carbonaceous coal-district. It is divided into three detached parts, separated from each other by a secondary limestone country, which not only envelops, but in continuation passes under the whole of the coal-district; a fact which was indisputably, though accidentally, proved by the Grand Canal Company, who sank a pit through eighteen yards of black slate-clay and flinty slate into the limestone in search of coal. The Leinster coal-district is therefore of subsequent formation to the limestone.

'The Munster coal-district occupies a considerable portion of the counties of Limerick and Kerry, and a large part of the county of Cork. It is by much the most extensive in Ireland; but as yet there is not sufficient information respecting the number, extent, or thickness of the beds of coal it may contain.

'Coal and culm have been raised for near a century in the neighbourhood of Kanturk, in the county of Cork. At Dromagh colliery, I understand, the work has been carried on to a very considerable extent, and its annual supplies of coal and culm have materially contributed to the agricultural improvement of an immense extent of the great maritime and commercial counties of Cork and Limerick, which must otherwise have continued neglected and unreclaimed.

'Many circumstances combine to make the examination of this district of peculiar interest and importance; and as a recent application has been made by the Cork Institution to the Dublin Society to aid the undertaking, it is probable that this immense district will shortly be minutely explored. From all that has been ascertained, it is very clear that the dip of the beds and the quality of the coal differ materially from those of the Leinster district. In the Munster district the beds run east and west, and dip to the south, forming an angle of 45°. In the Dromagh colliery, where all the beds which have been discovered have been successively and in general successfully wrought, four beds incline on each other, and at no greater distance than 200 yards. The first of these beds is a three-feet stone-coal, and is the leading bed. All faults, checks, and dislocations, similar to those which are discoverable in this bed, are in general to be encountered in the other three. The names of the four beds are, the *coal-bed*—this lies farthest to the north; the *rock-coal*, so called from its being comparatively of harder quality than the other beds; the *bulk-bed*, so called from its contents being found in large masses or bulks; and *Bath's bed*, so called from the name of a celebrated English miner, by whom it had been many years ago discovered and worked. The coal-bed consists of three-feet solid coal, and is not sulphureous; the rock-coal is nearly of the same thickness with the leading bed, but is very sulphureous, and, having the soundest roof, is the most easily wrought. The other beds are of the culm species, but of peculiar strength. * * * The bulk-bed forms immense bulks and masses of culm, in which the miners have frequently been unable to retain the ordinary directions of roof and seat.

'No work has been undertaken in the Munster coal-district to a greater depth than 80 yards. The present work at the Dromagh colliery is at that depth; it is heavily watered, and consequently expensively wrought. The quality of the coal and culm improves as the work descends. * * *

'The Connaught coal-district stands next in order of value and importance to the Leinster and Munster, and possibly may be found to deserve the first place when its subterranean treasures shall be explored. At present nothing is known, except that the outer edges of several beds of coal have been observed, but they have not been traced to any distance, so that their extent is by no means ascertained. The coal is of the bituminous species. This coal is particularly adapted to the purposes of iron-works, foundries, &c. &c.

'The Ulster coal-district is of trifling importance when compared with the foregoing. It commences near Dungannon, in the county of Tyrone, and extends in a northern direction to Coal Island, and in continuation to the neighbourhood of Cookstown. No beds of coal worth working have hitherto been discovered between Coal Island and Cookstown, but certainly the coal strata extend there. The principal collieries are at Coal Island and at Dungannon. The coal of this district is bituminous. I understand that indications of coal have been observed at Drumquin, in the county of Tyrone; and also at Petigoe, to the north of Lough Erne. Possibly the coal-formation may extend from the neighbourhood of Cookstown westward to the north of Lough Erne.

'Besides the foregoing principal coal-districts, there are others of less consequence. Bituminous coal has been found in the neighbourhood of Belturbet, in the county of Cavan, and at the collieries of Ballycastle, in the county of Antrim; but the Antrim coal-district is not very extensive. These collieries have been wrought for a number of years. The coals are of a slaty nature, and greatly resemble both the coal and the accompanying rocks which occur in Ayrshire, and probably they belong to the same formation.'

Continental Europe.—In the centre and south of France some small coal-fields occur in the valleys of the Loire, the Allier, the Creuse, and the Dordogne, the Aveyron [Aveyron], and the Ardèche, between ridges proceeding from the primitive central group connected with the Cevennes; and, in a few localities, some of the thickest beds of coal yet discovered have been found. In the north of France, the coal-formation occupies a very large tract of country, running westward from Hardinghen, near Boulogne, by Valenciennes, and thence up the Scheldt and down the Meuse to Eschweiler, beyond Aix-la-Chapelle. [Belgium.] The district along the Meuse, between Namur and Liege, is said to resemble in its geological structure, as well as picturesque features, the Somersetshire and South Gloucester district: the strata being broken and deranged, exhibit, if possible, still more contorted and inverted positions of the respective beds. The defiles of the Sambre and the Meuse (*Geol. Trans.*, vol. i., 2nd series) present an exact counterpart of those of the Avon and the Wye. The coal-districts in the north of Germany are probably the prolongation of the Belgium formation. On the north-east and south-east of the Harz mountains, near Ballenstadt and Neustadt, the coal-formation occurs resting on the transition rock of that group. In Saxony coal is found in many places along the northern foot of the Erzegebirge. It is extensively worked near Zwickau and near Dresden. There is a very extensive coal-district in Bohemia, extending into Upper Silesia. This district lies between the great primitive chain of the Erzegebirge and the Riesengebirge, on the north, and the great district of primitive slate which occupies the larger part of Bohemia south of the Beraun and Upper Elbe. More than forty beds of coal are supposed to be worked in this district.

---

* The counties are Antrim, near Ballycastle; Donegal, north of Mount Charles; Tyrone, in the Ulster coal-district, and at Drumquin; Fermanagh, north continuation of the Connaught coal-district, and at Petigoe; Monaghan, near Carrickmacross; Cavan, near Belturbet; Leitrim and Roscommon, in the Connaught coal-district; Westmeath, near Athlone; Queen's county, Kilkenny, and Carlow, in the Leinster coal-district; Tipperary, continuation of the same; and Clare, Limerick, Kerry, and Cork, in the Munster coal-district.

Good coal has been found in Southern Russia, near Toula, lat. 54°, long. 37°, where it is worked; but the quantity is so small, and the difficulty of working it beneath a loose and half-liquid bed of quicksand is so great, that it seems unlikely to be of much utility. Coal has also been worked at Bakhmont, lat. 48°, long. 38°, in the government of Katerinoslaf. (Mr. Strangways on the Geology of Russia. *Geol. Trans.*, vol. i., 2nd series, p. 35.) In Sweden coal occurs to the south of the primitive tract, near Helsingborg, at the entrance to the Baltic. Coal is also worked in the island of Bornholm. [BORNHOLM.]

Laborde mentions coal as occurring in Spain; in eight places in Catalonia, in three in Aragon, and one in New Castile. Coal, it is conjectured, will be found in several parts of continental Greece. On the north of Constantinople coal is said to be found.

Asia.—In Asia coal has long been worked in China, but what has hitherto been obtained is said to be very slaty. Coal is likewise found in the countries immediately around the Persian Gulf, but of a very indifferent description. In most parts of Cutch, coal occurs in abundance, and of good quality; it ignites quickly, and burns to a white ash. Coals are also found in Bundelcund. There are large mines in a district called Burdwan, 130 miles from Calcutta, now worked to the extent of 14,000 or 15,000 tons annually. They are situated on the banks of a river connected with the Hooghly, and were first worked about eighteen years ago, but they have not been in extensive operation more than ten or eleven years; the principal seam is about 9 feet thick, and is about 90 feet from the surface. Coal has likewise been got from a mine opened near Bhaugulpoor, on the Ganges, about 300 miles from Burdwan. Another coal-field has been discovered on the banks of the Hooghly, at a place called Merzipore, about 40 miles from Calcutta; the coal is found close to the surface, and the thickness of the principal seam is said to be two feet. Coal of good quality likewise occurs in the Birman empire.

In the United States of North America, east of the Appalachian range, there is an extensive coal-field in Virginia, twelve miles west of Richmond: it is about ten miles wide, and has been traced near forty miles. It is surrounded by primitive rocks, and said to lie also on primitive rock. This coal-field supplies the town of Richmond, and also Washington and other places to which it can be taken by land-carriage. In the great secondary formation west of the Appalachians, which consist of limestone, sandstone, slate-clay, and freestone, with vegetable impressions, a bed of coal is said to extend from the Ohio to the Tombigbee in Alabama. The coal commences at Cumberland, in the state of Maryland, between the Alleghany and Tuscarora ranges; and west of this town it occurs generally in beds varying from an inch to ten feet in thickness. About Wheeling, on the Ohio, a great quantity of coal is used for manufacturing purposes. The sandstone in this part is considered as the lowest member of the formation. The consumption at Pittsburg is also considerable. West of the Mississippi the argillaceous sandstone is associated with beds of coal and ironstone. The Ozarks contain beds of coal.

In the southern provinces of Chile there is an extensive coal-field, that is partially worked.

Nova Scotia contains a great quantity of coal. The great coal-field of Pictou has been traced from Carriboo Harbour to Merigomish, comprising an area of more than 100 square miles. The seams of coal resemble much more those of Staffordshire than those in the north of England. One bed is described by a practical miner, who went to Nova Scotia to superintend the opening of the mines, as 40 feet in thickness; it is not however equally good throughout, and it was thought advisable to work only 10 feet of the upper part. According to Bouchette the seams of this field vary in thickness from 1 foot to 50 feet. The coal is highly bituminous and burns well. There is another coal-field, also of considerable extent, in the north-west part of the county of Northumberland, between the river Macan and the shores of the Chignecti Channel. In this district there are eight strata of coal, varying from one to four feet in thickness. This coal is not considered so good as that of Pictou. There are also indications of coal in the township of Londonderry and at Onslow; on the north shore of the Mina's basin; at the head of Pomket Harbour, in the upper district of the county of Sydney; and on the south shore of Wallace Harbour, in the county of Cumberland. (Bouchette.)

Coals of excellent quality are got in Cape Breton. The coal-measures have been traced in the western part of the island, on Inhabitants River, at Port Hood, and at Mabou. On the east the Sydney coal-field is of great extent; it commences at Miray Bay and runs along the coast to the Great Bras d'Or, being in length about 40 miles, and averaging 5 miles in breadth. 'From a minute calculation, after deducting harbours, bays, and all other interpositions, it appears that there are 120 square miles of land, containing available veins of coal.' (Bouchette.) The measures in this district contain fourteen beds of coal, varying from 3 to 11 feet in thickness. The coal is wrought at Sydney Harbour and at Lingan.

Coal is found very abundantly in Australia, and is worked extensively in the Newcastle district, on the Hunter's River. A coal formation likewise occurs in Van Diemen's Land.

COAL PLANTS. That coal is the result of the mineralization of vegetable remains is abundantly proved, both by the numerous impressions of plants found in connection with it, and by the traces of organization which are still discoverable in it. Mr. Hutton has shown that it is possible to prepare the different varieties of bituminous coal in such a way as to render slices of them partially transparent, when the microscope shows the elementary tissue of the plants which have produced them. Cannel coal, he says, seems to retain traces of its structure through its whole mass, while it exists in fine coal in small patches only, which appear as if mechanically entangled. (*Fossil Flora*, ii., 25.)

In general the impressions of plants occur chiefly in the shale of the coal-measures, that is, in the mud which separates the seams of coal, or in the sandstone or ironstone associated with the coal formation; and as such impressions are much more distinct than any that occur in the coal itself, it is chiefly from them that our ideas of the vegetation from which coal has been produced have been derived. They are often present in inconceivable beauty and abundance, as may be imagined from Professor Buckland's graphic account of those in the coal-mines of Bohemia. In his 'Bridgewater Treatise,' he says, 'The finest example I have ever witnessed is that of the coal-mines of Bohemia just mentioned. The most elaborate imitations of living foliage upon the painted ceilings of Italian palaces bear no comparison with the beauteous profusion of extinct vegetable forms with which the galleries of these instructive coal-mines are overhung. The roof is covered as with a canopy of gorgeous tapestry, enriched with festoons of most graceful foliage, flung in wild irregular profusion over every portion of its surface. The effect is heightened by the contrast of the coal-black colour of these vegetables with the light ground-work of the rock to which they are attached. The spectator feels himself transported, as if by enchantment, into the forests of another world; he beholds trees, of forms and characters now unknown upon the surface of the earth, presented to his senses almost in the beauty and vigour of their primeval life; their scaly stems and bending branches, with their delicate apparatus of foliage, are all spread forth before him, little impaired by the lapse of countless ages, and bearing faithful records of extinct systems of vegetation, which began and terminated in times of which these relics are the infallible historians.'

Such remains consist chiefly of impressions of leaves separated from their branches, and of casts of trunks more or less in a broken state; and with them occur now and then pieces of wood or remains of trees, in which the vegetable texture is to some extent preserved. Of the leaves the greater part is more or less mutilated; those of ferns, which are extremely numerous, have lost their fructification in the majority of instances; and it frequently happens that the leaflets of compound leaves have been disarticulated either wholly or partially. Stems or trunks are in all cases in a state which must be supposed to result from decay previously to their conversion into coal; destitute of bark, or with the principal part of that envelope gone, and often pressed quite flat, so that all trace of their original convexity is destroyed. Where ripe fruits are met with, they are not in clusters as they probably were when alive, but separated into single individuals. Of flowers there is no trace that can be satisfactorily identified; for Antholithes Pitcairniæ, the most perfect that has yet been discovered, is altogether of a doubtful nature. The authors of the 'Fossil Flora' represent it as having been so much decayed at the time it was imbedded in the shale, that all its parts are blended together, and no longer distinguishable as separate organs.

If remains such as these, although of recent plants, were submitted to a botanist for examination, he would find it impossible to form any other than a general idea of their nature, and he would be unable to speak with any confidence as to the precise plants which produced them. Such being the case with recent fragments, where colour, texture, odour, flavour, and many other points would exist, of which a skilful botanist would avail himself, independently of the more important points of structure of which systematic writers principally make use, it is obvious that the difficulty of determining the nature of the fossil remains of plants must be far greater; for with them the evidence upon which an opinion is to be formed is of the most circumscribed and sometimes doubtful nature: so great indeed is the difficulty, that a French botanist of no mean reputation is known to have declared that all speculations upon the nature of antient vegetation ought to be referred to the romance of natural history, and have no concern with science. There is little doubt now that some of the theories to which the study of the vegetable remains of the coal-measures has given rise are romantic enough; but on the other hand it is equally certain that they furnish some most important and precise evidence as to the nature of the vegetation with which our planet was clothed in the earliest ages of the existence of organic matter.

Coal plants may be divided for practical purposes into three classes: 1, those of which only wood still containing organic structure has been found; 2, those which have an obvious analogy with recent plants; 3, those with which no existing analogy has been traced. We select a few of the most remarkable cases under each of these heads.

1. *Coal plants of which wood only containing organic structure has been found.*

The existence of wood in the coal formation with its texture still preserved, is a discovery of very modern date. Mr. Nicol, of Edinburgh, claims the credit of having first invented the art of preparing fossil wood so as to show its structure microscopically; Mr. Witham has investigated the subject extensively, and he has been followed by Messrs. Lindley, Hutton, and others. The result of these inquiries has been, that wood still preserving its texture exists in a mineral state extensively throughout the coal-mines of the North of England; that it in most cases has a structure analogous to, although not identical with, that of recent coniferous wood; and that in those cases in which its structure is not coniferous, it is unlike that of any existing trees.

Coniferous wood is known among other things by the presence of small disks upon the sides of its woody tubes; differences in the arrangement of these disks have given rise to the formation of the genera *Peuce* and *Pinites*, to one or other of which all the coniferous coal-wood seems referrible. Mr. Nicol believes that it may all be referred to either the existing genera Pinus or Araucaria. Specimens of this kind of wood occur sometimes of considerable size. A trunk of Pinites Brandlingi has been found 72 feet long, and another of Pinites Withami 36 feet long.

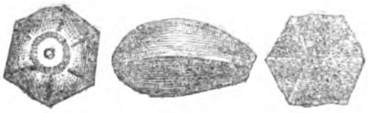
The wood, to which Mr. Witham's genus *Anabathra* apparently belongs, is known by its longitudinal section representing tubes marked by parallel transverse lines resembling the steps of a ladder. This is very uncommon, and is stated by Messrs. Lindley and Hutton to belong to the genus *Stigmaria*, which will be mentioned hereafter.

One specimen in iron-stone also has occurred of the wood of the genus Lepidodendron; it consists principally of loose cellular tissue, having near the centre a zone of spiral vessels, connected with the bases of the leaves by arcs of spiral vessels, and having rudiments of wood on the outside of the zone. (*Fossil Flora*, 2. tt. 98 and 99.)

2. *Coal plants which have an obvious analogy with recent plants.*

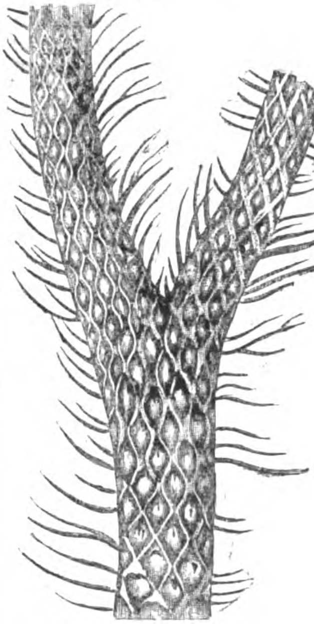
Coniferous plants have left few remains, except wood, by which they can be recognised. A cone of *Pinus anthracina* has been met with, and there is reason to believe that certain stems called *Bothrodendron*, having numerous minute dots upon their surface, and deep circular oblique concavities, four or five inches across, at intervals of ten or eleven inches, are also remains of trees of this description. It is probable moreover that some of the fossils referred to the genus *Lepidodendron* are really coniferous plants, especially *Lep. longifolium;* but upon this point nothing certain is known.

Palms occur occasionally, but in solitary fragments; they are among the rarest of well-identified coal plants. Their trunks have not been discovered; their leaflets are mostly of a wedge-shaped figure, resembling those of Caryota or Wallichia: their fruit, to which the name of *Trigonocarpum* is given, are more frequent, and are always found in clusters, but separate from each other. It would seem as if the bunches of their fruit had lain in water till the pulpy parts rotted away, and the nuts fell asunder and settled down into the mud, where they were finally imbedded. These remains are generally oblong, three-sided or six-sided bodies, not more than an inch long. The following represents some states of Trigonocarpum Nöggerathi.

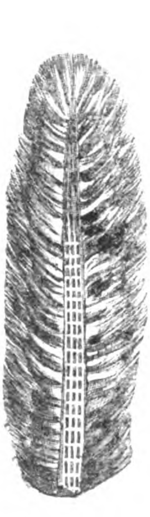


[Trigonocarpum Nöggerathi.]

Lycopodiaceous plants, or what are considered analogous to them, form a very large proportion of the vegetable remains of the north of England coal-field. They are represented by impressions closely covered either with lozenge-shaped spaces disposed in a spiral manner, or by small scale-like leaves, which are supposed to have produced those spaces by falling off. When they branch, they have often been observed to do so in a forked or dichotomous manner. Sometimes they are minute, and no larger than existing Lycopodia, but they are occasionally found of considerable size, some having been seen which, although mere fragments, were between forty and fifty feet long, and more than four feet in diameter. An idea of their appearance will be gained from the accompanying figure of Lepidodendron Sternbergii.



[Lepidodendron Sternbergii.]



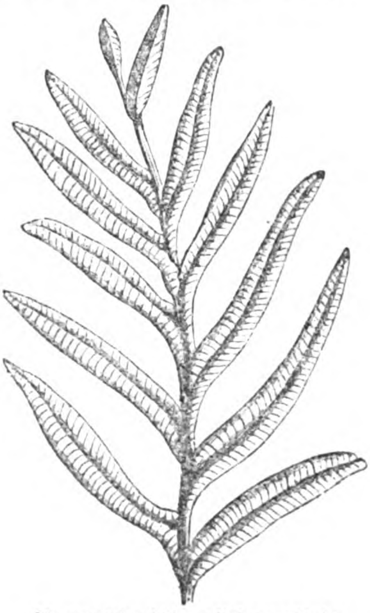
[Lepidostrobus variabilis.]

Associated with them are narrow sharp-pointed leaves, resembling scales, which no doubt belonged to them, but which are distinguished by the name of *Lepidophyllum*. In the same formations are found cones of different sizes, consisting of small sharp-pointed lax scales, in the axils of which were seeds: these have been supposed to be the fructification of Lepidodendron, but as there is no actual certainty of the fact, they bear the name of *Lepidostrobi*. The above figure represents Lepidostrobus variabilis.

Lepidodendra are usually quoted as an instance of antient species belonging to the same genus as modern plants of very humble stature (for existing Lycopodia, although they acquire sometimes the length or height of three or four feet, are always more like mosses than trees), having arrived at gigantic dimensions in the remote ages when coal was deposited. But it is highly probable that this notion is altogether unfounded; for, in the first place, there is no certainty whatever that the most gigantic Lepidodendra were not fir-trees, analogous to Araucaria; a conjecture which is rendered the more probable by Mr. Nicol's discovery that some of the specimens of fossil coniferous wood are nearly identical with the wood of that genus. Now the Norfolk Island pine, which is a species of Araucaria, is one of the largest of known trees. In the second place, it has been proved that Lepidodendron Harcourtii at least is not a Lycopodiaceous plant at all, but an extinct genus, intermediate in organization between Coniferæ and Lycopodiaceæ, connecting Gymnosperms and Acrogens more directly and satisfactorily than any known plant. It is impossible to say how many other species of Lepidodendron may not agree with L. Harcourtii, and it must be obvious that, being an extinct form, we have no more reason to be surprised at its being larger than the genus Lycopodium now is, than we should have at finding a tree fern, like Alsophila brunoniana, whose stem is between forty and fifty feet high, in the same natural order with the common Polypodium of our hedges. With regard to the small species of Lepidodendron, it is more probable that they belonged to the genus Lycopodium; but there is nothing remarkable in their stature.

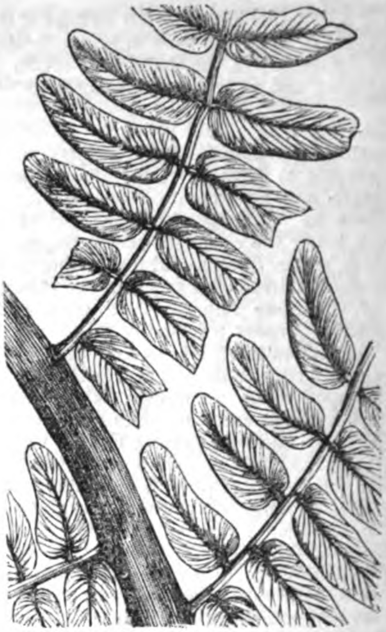
Ferns are the most abundant of all plants in the shale of the coal, almost every yard of it being more or less marked by their impressions, and very often containing them in great multitudes. It has been estimated that of the vegetable remains belonging to the Coal Flora, one-half at least of the species are ferns. They are in most cases destitute of fructification, so that they cannot be arranged according to the system in use for recent species; and consequently M. Adolphe Brongniart, the great writer upon these subjects, has divided them into genera characterized chiefly by the way in which the veins are disposed. The number of ferns renders it convenient that some such classification should be formed, and M. Brongniart's plan has been adopted by all other writers. It is no part of our object to go into such details in this place, but it will be useful to many of our readers to know what the differences are between some of the most common of these fossil genera. Such are the following:—

Pecopteris consists of species whose leaves are once, twice, or thrice pinnated, with the leaflets either adhering by the whole breadth of their base, or by the centre only. The midrib runs quite through to the point, and the veins are planted upon it somewhat perpendicularly.



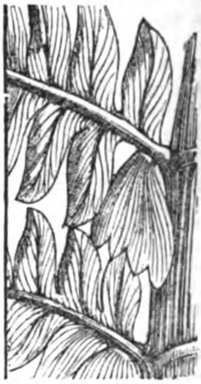
[Pecopteris lonchitica, a little magnified.]

Neuropteris has leaves divided like those of Pecopteris, but the midrib does not reach the apex of the leaflets; on the contrary, it divides off right and left into veins, and gradually disappears.



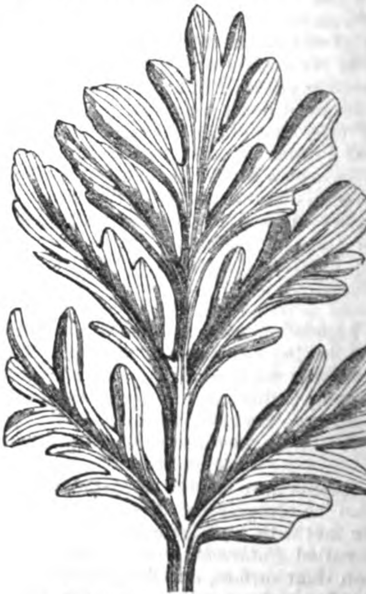
[Neuropteris gigantea.]

Odontopteris has leaves like the last, but its leaflets adhere to the stalk by their whole base; there is no midrib; and the veins spring side by side at once from the base of the leaflet, passing onwards towards the point.



[Odontopteris Brardii.]

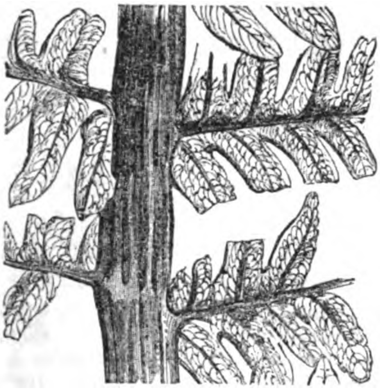
Sphenopteris has twice or thrice pinnatifid leaves; th leaflets are narrowest at the base, and the veins generall



Sphenopteris artemisiæfolia, magnified.

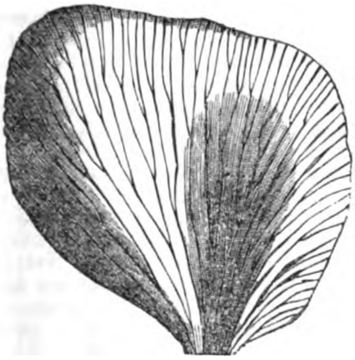
arranged as if they radiated from the base; the leaflets are more frequently wedge-shaped than any other figure.

Lonchopteris has the leaves several times pinnatifid, and the leaflets more or less united to one another at the base; there is a distinct midrib, and the veins are reticulated.



[Lonchopteris Bricii.]

Cyclopteris has the leaves simple, and either altogether undivided, or only lobed at the margin; they are more or less orbicular, and are filled with veins radiating from the base; there is no midrib. Specimens of this genus are common in ironstone nodules.



[Cyclopteris orbicularis.]

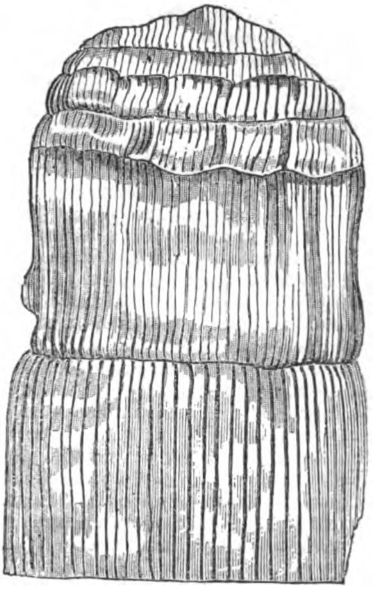
Schizopteris is like the last, except that the leaf is deeply divided into numerous unequal segments, which are usually lobed and taper-pointed.

Under the name of *Caulopteris* are comprehended all the kinds of stems of tree ferns. They are found in the form of short, round, or compressed truncheons, marked externally by oblong scars of considerable size, much wider than the spaces that separate them, and having their surface irregularly interrupted by projecting points. Such appearances are owing to the manner in which the woody parts of the leaf when fresh were connected with the stem. The fragments to which this name is given no doubt belong to leaves bearing other names; but as the stems and leaves are never found united, it is impossible to identify them. Remains of tree-fern stems are of such rare occurrence, that up to the present time not more than two or three specimens have been found in the rich coal-fields of Great Britain.

3. *Coal plants with which no existing analogy has been satisfactorily traced.*

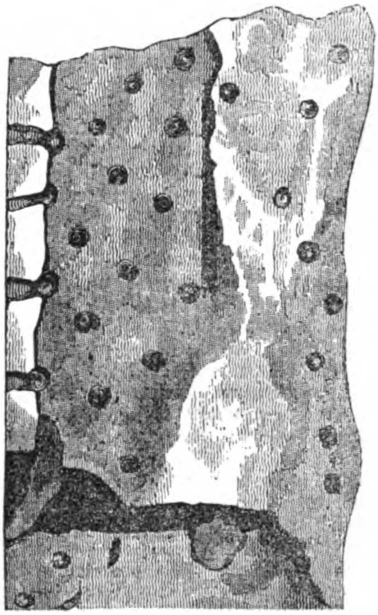
Calamites are fossils found in short, jointed, cylindrical, or compressed fragments, with channels furrowed in their sides, and sometimes partially surrounded by a bituminous coating, the remains of a cortical integument.

They were originally hollow, but the cavity is usually filled up with the substance into which they themselves are converted. They were separable at their articulations, and, when broken across at that part, show a number of striæ originating in the furrows of the sides, and turning inwards towards the centre of the stem, which however they do not reach. It is not known whether this structure was connected with an imperfect diaphragm stretched across the hollow of the stem at each joint, or whether it merely represents the ends of woody plates of which the solid part of the stem was composed. Their extremites have been discovered either to taper gradually to a point, or to end abruptly, the intervals becoming shorter and smaller. The latter are believed to have been the root end of these plants, the others the extremity of their branches. Various speculations upon the nature of these plants are to be found in M. Adolphe Brongniart's works, and in the 'Fossil Flora.' The former botanist concludes that they were plants allied to Equisetum, only of a more gigantic stature. (Equiseta are slender, weak-stemmed, erect plants, not more than two or three feet high; while Calamites have been found with a diameter of fourteen inches.) Later botanists, on the contrary, adduce what they consider ample evidence to show the supposition that Calamites were analogous to Equiseta to be unfounded; and that they more probably were a race of plants which have now become extinct. It is particularly urged that the presence of bark in Calamites, the existence of which M. Adolphe Brongniart admits, is quite conclusive that those plants did not even belong to the same natural class.



[Calamites dubius.]

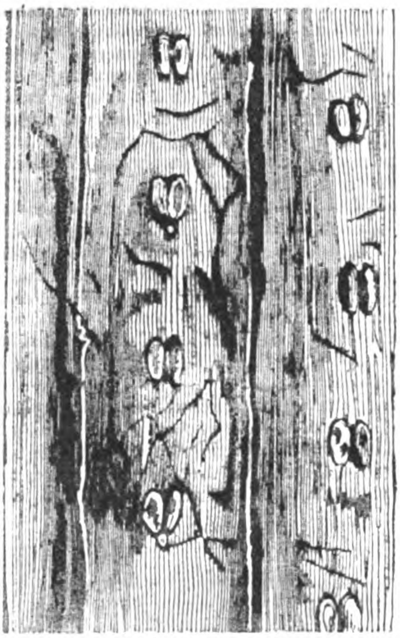
Stigmaria is one of the most common of all plants in the coal formation; not a mine is opened, nor a heap of shale thrown out, but there occur fragments of an irregularly compressed roundish form, apparently portions of a stem, marked externally with small cavities in the centre of slight tubercles



[Stigmaria Ficoides.]

arranged irregularly, but somewhat in a quincuncial manner. The axis of these fragments is often hollow, or different in texture from the surrounding part. From the tubercles arise long ribbon-shaped bodies, said to have been traced to the length of 20 feet. For a long time no more was known of these plants. A few years ago Mr. Hutton discovered that such fragments as we have just described are portions of the extremity of the arms of a huge dome-shaped body which divides into twelve limbs, each of which spreads horizontally from the edge of the dome, usually dividing into two arms. From more recent observations it has been ascertained that the arms of this plant consisted of a mass of cellular substance, having in its centre a hollow cylinder composed exclusively of spiral or scalariform vessels, and destitute of medullary processes. It is useless to enumerate the conjectures which have been formed concerning the real nature of this strange production; all that can safely be asserted about it is, that it was unquestionably a vegetable, for even that might have been doubted in the absence of some of the evidence that now exists. We are very much of opinion that it will eventually be ascertained to be something altogether different from any plant with which it has been yet contrasted: see observations further on.

Sigillaria comprehends all those columnar gigantic stems which occur commonly in the sand-stone of the coal in an erect or nearly erect position, but which are prostrate and crushed flat in the coal-shale, and which are marked by flutings with a single row of small scars between them. In diameter they vary from 6 to 36 inches, and they must have sometimes been full 40 or 50 feet high.

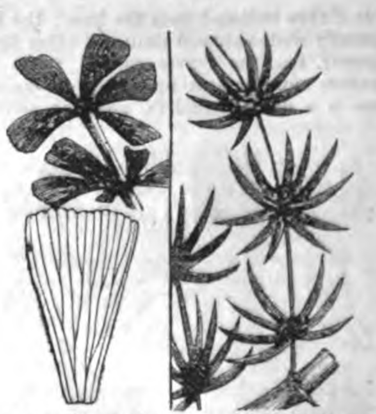


[Sigillaria reniformis.]

It is believed, from the very compressed state of many specimens, that these plants must have been of a soft nature, and, from the general absence of scars of large size, that they must have been very little branched. The presence of a distinct bark proves them to have been Exogens of some kind. They have been supposed to be tree-ferns, but that is highly improbable; again, they have been conjectured to be analogous to the torch-thistles (Cacti) of the Tropics, which is far more probable. But in fact no evidence exists upon which a precise opinion can be formed. Is it quite impossible that Sigillarias and Stigmarias are both the same thing, the former being the stem, the latter the roots? Compare with each other tab. 54, the base of *fig.* 1 and *fig.* 2, with tab. 31, *fig.* 2, of the 'Fossil Flora.'

Asterophyllites are very common plants, with narrow pointed, whorled leaves, which vary in figure and in size, but which, together with the slenderness of the stem to which they belong, give the plants much the appearance of the modern genus Galium.

Sphenophyllum, with many of the characters of the last genus, has broad wedge-shaped leaves, the veins of which are forked. That circumstance has led to the notion that it was related to ferns, especially to the genus Marsilea.



[Sphenophyllum Schlothaimii.] [Asterophyllites foliosa.]

Such are the more common of the plants whose remains are traced in the coal-measures. One of the first things which strikes us in casting the eye on the list is the little variety of form apparent in the old Flora. Instead of the infinite diversity of plants which are contained in a modern forest, nothing here presents itself except fir trees, ferns, a very few palms, and a small number of species whose nature is unknown. Not a trace is found of grasses, or the numerous herbs and shrubs that are now met with in all regions clothed with vegetation; and of the vast class of Exogens not one authentic instance occurs. Ferns, too, would seem to have constituted in themselves one-half of the entire Flora, and yet it is only in a few rare cases that they have been met with in a state of fructification. These circumstances have led to the hasty inference that in the beginning nature was in reality but little diversified; that a few forms of organization of the lower kind only were all that clothed the face of the earth; and that it was only in after ages that Nature assumed her many-coloured ever-varying robe. And yet it has been at the same time admitted that in those early days vegetation was more luxuriant and vigorous than at the present hour. It is not a little singular that the true explanation of this circumstance should not have been hit upon without any direct experiment having been instituted for the purpose of demonstrating how it is really to be explained; for considering that all geologists are of accord in the opinion that the plants which formed coal were for a period of some duration floating in water, a partial destruction of them might easily have been supposed to be the result. Professor Lindley has recently proved that plants are capable of enduring suspension in water in very different degrees, some resisting a long suspension almost without change, others rapidly decomposing and disappearing. One hundred and seventy-seven plants were thrown into a vessel containing fresh water; among them were species belonging to the natural orders of which the Flora of the coal-measures consists, and also to the common orders, which, from their general dispersion over the globe at the present day, it might have been expected should be found there. In two years one hundred and twenty-one species had entirely disappeared; and of the fifty-six which still remained, the most perfect specimens were those of coniferous plants, palms, lycopodiaceæ, and the like; thus showing in the clearest manner that the meagre character of the Coal Flora may be owing to the different capabilities of different plants of resisting destruction in water. The same experiment accounts for the want of fructification in fossil ferns; for it showed that one of the consequences of long immersion in water is a destruction of the fructification of those plants.

A much more important fact is the presence of certain tropical forms of vegetation, such as palms and tree-ferns, in the coal; and the quasi-tropical character of other species, as Araucaria-like Coniferæ. This is the more startling when connected with another fact, that the coal-measures of Newcastle are of the same age as those of Newfoundland, and even of Melville Island, in 75° N. lat.

From this it has been inferred that the northern parts of the world enjoyed in remote ages a climate where frost and snow, and the inclement seasons of Arctic regions, were unknown; that they were at least as hot as equinoctial countries now are; and that the inhospitable hyperborean plains of Melville Island at one time displayed the noble scene of a luxuriant and stately vegetation. Palms, it has been said, were there, and they are the especial and princely denizens of the tropics; tree-ferns occur, and they now only exist in the primeval forests of the torrid zone, haunting their deepest recesses, breathing a damp and equable atmosphere, and living, like vegetable eremites, without even a parasite to fix itself upon their trunks and keep them company. Stigmarias, Sigillarias, and even Calamites, have been enlisted in the cause of this theory, notwithstanding that no one can say what they may have been. And in confirmation of all this, the preponderance of ferns has been appealed to as having its parallel no where except in the hottest and dampest islands of Polynesia.

The advocates of these opinions have not however been permitted to hold their ground in peace. It has been asserted that the presence of these tropical forms of vegetation in northern latitudes is no proof of what the climate in which they were deposited formerly was, because they may have been drifted to their present situations by currents. The perfect state of many of the remains offers however great difficulties in the way of this supposition; for although they are very much broken, yet the angles of most fossil plants are by no means water worn, and in Sigillarias, &c., are as sharp as they ever were. Nor is the state of those tropical stems and fruits, which in modern times reach the coasts of Ireland and Norway, at all like that of the buried plants of the coal-measures.

Another difficulty in the way of admitting a high temperature in northern regions in former days is suggested by considering the duration of the days. Without a diurnal change of light and darkness plants cannot exist: absence of light blanches them, by the accumulation of undecomposed carbonic acid; absence of darkness destroys or dwarfs and deforms them, by the incessant decomposition, of their carbonic acid. Now, however this may be reconciled with a country like England, in which the winter days are of moderate length, it is less reconcilable with the northern parts of North America, and not at all with Melville Island, in which there are 94 days when the sun is never above the horizon, and 104 days that he never sets; and it will hardly satisfy the objection to call in the aid of long-continued auroræ boreales, because it is solar light, and solar light only, which, so far as we know, will stimulate the digestive functions of plants. To admit therefore the presence of a tropical vegetation in former days in Melville Island, or Baffin's Bay, seems to carry with it the necessity of also admitting that a change has occurred in the position of the earth's axis of rotation—an assumption for which we have no evidence at all.

These points were adverted to in a lecture given by Professor Lindley at the London University on the 16th March, 1836, and at the same time some views of his own were sketched out, with which we conclude the present article.

He, in the first place, adopted entirely the opinion that the plants of the English coal-measures had not been drifted from any considerable distance, but had grown at the most within a few hundred miles of the places where they are now deposited, and probably in their very vicinity. But from this statement was excepted the coal of Melville Island; for he asserted that, although the vegetable impressions in the English coal-measures were by no means water worn, yet those in the British Museum from Melville Island were so rubbed and damaged, that they might have travelled from the very equator before they were deposited. This rendered it unnecessary to discuss the question of the possibility of plants growing without light under a supposed high temperature, and to a considerable size, because it cannot be denied that an English winter at the present day has light enough to answer all the purposes of a vigorous vegetation; and the same is true of Newfoundland, and those parts of the United States of America in which the coal plants are most unequivocally of the same nature as those of Newcastle.

The great point for consideration was the evidence which, it is asserted, the coal-measure plants afford of the climate of Great Britain, and the north of Europe generally, having formerly been tropical. This opinion has been founded upon three classes of facts, each of which requires separate examination: the one, the excessive development of certain forms of vegetation; another, the presence of the remains of palms and tree-ferns, which are usually considered incapable of existing unless in a tropical atmosphere; the third, the excessive disproportion of ferns to other plants.

Sigillarias, Stigmarias, Lepidodendra, and Calamites, have been asserted to be enormous forms of natural orders, now known only in a comparatively pigmy state. Sigillarias have been called huge tree-ferns, Stigmarias and Lepidodendra have been described as gigantic Lycopodiaceæ, and Calamites have been considered an excessively developed ultra-tropical form of Equisetum. But these assertions are of the most gratuitous kind, and are incapable of being maintained upon admissible botanical reasoning. Whatever Sigillarias, Stigmarias, and Calamites may really have been, there is no reason for supposing them either related to tree-ferns, Lycopodia, or Horsetails; and Lepidodendron has been demonstrated to have been a genus intermediate between Lycopodia and fir-trees. It is almost certain that all these plants are in reality destitute of living analogies; and therefore as we do not know what they were, we have no means of judging what kind of climate they required. Supposing that some of the Lepidodendra were closely allied to the modern genus Araucaria, as is highly probable, yet that fact does not afford any proof of a tropical climate; for Araucaria Dombeyi now inhabits the cold mountains of Southern Chile, and is at this day uninjured in the severest of our English winters; while Cunninghamia sinensis, and species of Callitris or Dacrydium, with which other remains of Lepidodendra may be compared, although not European, are by no means of tropical habits, but are found on the mountains of New Zealand and Van Diemen's Land, where they are exposed to a far from temperate climate. Moreover Salisburia adiantifolia, which would certainly be considered a tropical form of Coniferæ, if found in an extinct state only, is one of the hardiest of trees, and a native of the rigorous climate of Japan. Further than this, it was observed that supposing Sigillarias and Stigmarias could be found to have been succulent plants, allied to Cactaceæ or Euphorbiaceæ, as some think, still no real evidence of their having required a tropical climate for their development would be afforded by them, because there is nothing in the mere organization of succulent plants which unfits them for cold climates. A capability of enduring cold is something immaterial and independent of organization, about which nothing can be judged *à priori;* for turnips, cabbages, Jerusalem artichokes, houseleek, and many other hardy plants, are in parts as succulent as Cactaceæ. All arguments therefore to prove that the north of Europe was formerly tropical, deduced from the presence of such plants as those now mentioned, are inadmissible.'

Nor are those derived from the presence of palms and tree-ferns of much greater force. For, in the first place, it is to be remembered that such remains are exceedingly rare; secondly, that they are much damaged, as if they had been dashed about a good deal before they were deposited; and thirdly, that such plants are among those which are capable of resisting the action of water for a considerable period. Independently however of these considerations, there are others which are of more importance. Neither palms nor tree-ferns are exclusively tropical: it is true that at the present day the principal part of such species do inhabit the tropics, but there is a sufficient number of exceptions to justify the opinion that others may have existed of still more hardy habits. To say nothing of the date-palm itself, which is cultivated in Sicily, and even at Bordighiera, in Liguria; or of the palmetto (Chamærops humilis), found as far north as Nice; or of the New Zealand Areca, which is seen in places where the ground is sometimes covered with snow for several days; or of the doubtful Palma magellanica, which Humboldt states certain Spanish voyagers to have seen in 53° S. lat.—there is the gigantic wax-palm of the Andes [CEROXYLON], which rears its lofty trunk in climates too inhospitable for any other palm. It is chiefly, says Bonpland, among the snow-clad summits of Tolima, San Juan, and Quindiu, that this palm occurs. 'The elevation above the sea of this species presents a very striking phenomenon with reference to botanical geography. Usually in the tropics, palms are not found at elevations exceeding 3000 feet, the cold of higher regions preventing them from approaching nearer to the limits of perpetual snow. The palm of Quindiu offers a very rare exception to this law of nature. It is hardly seen in the plains; it first begins to appear at an elevation of 5400 feet, which is about that of the Puy de Dôme, or the Passage of Mont Cenis. It therefore appears to shun the excessive heats of less elevated localities. Its lowest limit is higher than that of the Cinchona. We observed it plentifully at the height of

5700 feet, which is 6000 feet higher than species of palms are usually met with, and not more than 2400 feet from the region where the soil is occasionally covered with snow.' (Humb. and Bonp., *Pl. Æquinoct.*, vol. i.)

As for tree ferns, we have them in New Zealand, and especially on the south side of Van Diemen's Land, where the mean temperature probably does not exceed 54° Fahrenheit. So that, all things considered, it is by no means safe to take the remains of these plants as good evidence of a tropical climate, or indeed of a climate materially unlike that which we now experience.

The only remaining argument to be considered is that derived from the great preponderance of ferns in the Coal Flora. It is said by Adolphe Brongniart, that as it is only in damp tropical regions that we now find ferns equal in the number of their species to all the species of other plants, and as this same proportion is found in the Coal Flora, that therefore the climate under which the Coal Flora was produced must have been damp and tropical. But as, by the experiment already mentioned, it was shown that when a given number of plants of entirely different habits are plunged into the same vessel of water, by far the greater part is decomposed before ferns begin to be affected, it is obvious that no estimate of what the proportion of ferns to other plants really was can now be formed; and consequently this argument also falls to the ground.

These statements must, we think, render it apparent that geologists have been too hasty in coming to the conclusion that the north of Europe was formerly tropical; and that if the facts we actually possess are soberly examined, they do not amount to more than this:

1. That coal is of vegetable origin.
2. That at the period of its deposit, the earth was covered with a rich vegetation, of which only a small portion has been preserved, and that of this portion all the species and several of the races are totally unknown at the present day.
3. That the climate may possibly have been something milder than it now is, but that there is no evidence in the vegetable kingdom to show that it was materially different from that of the present day.

It may possibly have been expected that in the course of these remarks we should have touched upon the modern theory that species have been gradually becoming more and more completely organized from the earliest period of the creation to the present day; that the simplest forms were those which first appeared; that they were succeeded by others of a more complicated structure, and that it is only in these later days that the most perfectly constructed species have appeared. Upon this subject we have only to remark, that so far as the vegetable kingdom is concerned, the theory is not supported by a shade of evidence; and we therefore do not think it necessary to give it further notice.

COAL TRADE. The quantity of coals shipped coastwise from ports of Great Britain to other ports of Great Britain and to Ireland amounted, in the year 1835, to 6,117,993 tons; and the quantity exported to the British colonies and to foreign countries, in the same year, was 736,060 tons; making an aggregate of 6,854,053 tons of coals sea-borne from the maritime districts. The market of London alone required a supply of 2,298,811 tons, for the conveyance of which 7958 ships (which make repeated voyages) were employed. The great towns of Lancashire, of the three Ridings of Yorkshire, of Nottinghamshire, Derbyshire, Leicestershire, Warwickshire, and Staffordshire, are supplied by canals or by land-carriage from collieries in the respective counties here enumerated. In 1816 a committee of the coal-owners of Northumberland and Durham was commissioned to inquire as to the quantity of coals then sent by inland navigation and by land-carriage to different parts of the kingdom. The result of their inquiries was that 10,808,046 tons were annually so sent. There can be no doubt that if this estimate were correct at the time, the quantity must have been greatly increased during the last twenty years. In estimating the annual consumption of the country, it is also necessary to take into account the quantities used upon the spots where the collieries are situated. The town of Sheffield alone requires for manufacturing and domestic purposes more than half a million of tons annually drawn from collieries on the spot; and it has been estimated that the iron-works of Great Britain, most of which are situated in spots where coal is found, require every year, for smelting the ore and converting the raw material into bars, plates, &c., more than five millions of tons. The total consumption of coals within the United Kingdom has been variously stated at from fifteen to thirty millions of tons per annum; recent parliamentary inquiries lead us to conclude that the larger estimate is not much, if at all, exaggerated. Mr. Taylor, whose experience in the various branches of mining operations is equal to that of any person living, has given the following estimate, which agrees substantially with estimates formed by Mr. Stevenson and Mr. Bakewell, previously to the inquiries to which reference has just been made:—

	Tons.
'The annual vend of coals carried coastwise from Durham and Northumberland is	3,300.000
Home consumption, say one-fifth	660,000
	3,960,000
Which quantity supplies about 5,000,000 persons; and supposing the whole population of Great Britain to be 15,000,000, this must be trebled; for though these two-thirds of population are perhaps less able to afford fuel, yet, taking into consideration the manufacturing districts and the cheapness of coal in the interior, the estimate will not be too high	11,880,000
Consumed by iron-works, say 600,000 tons of metal, to produce which requires at least four times the quantity of coal in making even pig metal; and the extraordinary consumption in the Cornwall, &c. mines	3,000,000
Consumed in Great Britain	14,880,000
Exported to Ireland, say	700,000
Total tons, exclusive of foreign exportation	15.580,000'

It is probable that the foregoing estimate is considerably short of the present consumption, which has increased with the increasing population, and with the growth of the manufacturing interests. The following estimate, which can still only be offered as an approximation, is made upon the same principle as that assumed by Mr. Taylor, but applying to it the actual quantities ascertained from recent parliamentary returns:—

	Tons.
The quantity of coals carried coastwise from Durham and Northumberland, in 1835, was	43,68,144
Home consumption, one-fifth, which is probably much under the truth, from the recent multiplication, in those counties, of manufactures in which the cost of fuel is a principal consideration	873,629
	5,241,773
This quantity trebled, upon the principle assumed by Mr. Taylor, will amount to	15,725,319
Consumed by iron-works and mines, double the quantity estimated by Mr. Taylor, who has taken no account of that consumption as regards iron-works beyond the first process, in which alone, because of increased production, the full allowance of 3,000,000 tons are now used, say	6,000.000
Consumed by Great Britain	21,725,319
The shipments to Ireland in 1829, the last year as to which any specific parliamentary return has been made, were 840,246 tons. These shipments had then (1829) been for some years steadily increasing at the rate of 100,000 tons annually; and as the causes for that increase have since continued to operate, it may be fairly assumed that the shipments now amount to	1,000,000
Waste by screening, as explained below	6,628,218
Total, exclusive of foreign exportation	29,353.537

It was long considered politic to check the exportation of coals to other countries, both through fear of exhausting the mines, and because it was imagined that our superiority as manufacturers might be endangered. A heavy export duty was accordingly levied, amounting to 17*s.* the chaldron Newcastle measure, or 6*s.* 5*d.* per ton upon large, and 4*s.* 6*d.* the chaldron, or 1*s.* 8*d.* per ton, upon small coals.

In 1831 these duties were modified to 3*s.* 4*d.* per ton upon large, and 2*s.* per ton upon small coals; and in 1835 they were repealed, with the exception of an ad valorem duty of 10*s.* per cent. A considerable revenue was for many years raised from all coal carried coastwise by sea from one part of the kingdom to another. When first imposed, in the reign of William III., this tax was 5*s.* per chaldron, but was raised during the war of the French revolution to 9*s.* 4*d.*, at which rate it was continued until 1824; it was then reduced to 6*s.*, and in 1831 was wholly repealed. Although the government has remedied the evil so far as the public revenue is concerned, the consumer is still burthened in some places with local or municipal duties, &c. Thus in the city of London the corporation was empowered, by the Acts 10 Geo. IV., c. 136, and 11 Geo. IV., c. 64, to levy eight pence per ton 'for providing for the payment of the interest and ultimate liquidation of monies borrowed for making the approaches to London bridge.' One penny per ton is also levied under the Act 47 Geo. III. for establishing a market for the sale of coals; and under the Act 1 and 2 William IV., c. 76, four pence per ton 'for metage by prescription and charters,' making together 1*s.* 1*d.* per ton upon all coals brought coastwise to the port of London. By letters patent granted by Charles II., the duke of Richmond was entitled to receive 1*s.* per chaldron, Newcastle measure, on all coals shipped in the river Tyne to be consumed in England; and on the average of ten years ending 1799, the amount of that duty had been 21,000*l.* a year. On the 19th of August, 1799, the Treasury agreed with the duke for the purchase of this luty by an annuity of 19,000*l.*, which sum was charged upon the consolidated fund, to be paid quarterly. The sum issued by the Exchequer at three several periods for the purchase of a perpetual annuity of 19,000*l.* instead of those Exchequer payments was 490,833*l.* 11*s.* 6*d.*; but the bargain has proved by no means an improvident one on the part of the public, the sums received by the Custom House, as the representative of the duke of Richmond, from August, 1799, up to March, 1831, when all coasting duties ceased, having exceeded the payments made from the Exchequer by 315,000*l.* The total revenue derived from the coasting duties on coals in 1830, the year preceding its repeal, was 1,021,862*l.*

The quantity and declared value of coals, culm, and cinders exported from the United Kingdom to British colonies and foreign countries, in each year from 1827 to 1835, have been as follows:—

	Tons.	£.		Tons.	£.
1827	368,679	153,387	1832	588,446	228,615
1828	357,864	145,943	1833	634,448	231,344
1829	371,271	147,309	1834	615,255	220,746
1830	504,419	184,464	1835	736,060	244,898
1831	510,831	199,760			

The British colonies and foreign countries to which shipments were made in 1835, together with the quantity and value sent to each, were as follows:—

	Tons.	Value.		Tons.	Value.
Russia	42,061	£.11,425	Mauritius	1,039	£. 650
Norway	5,602	1,697	East India Company's Territories and Ceylon	2,775	1,784
Sweden	16,076	3,741	Indian Islands	126	50
Denmark	83,109	20,658	Philippine Islands	201	126
Prussia	43,675	9,336	China	429	175
Germany	66,055	15,177	N. S. Wales and V. D. Land	20	8
Holland	115,138	35,032	Brit. N. A. Colonies	38,565	16,359
Belgium	599	178	Brit. W. Indies	61,054	36,872
France	104,138	31,647	Hayti	43	23
Portugal	11,981	2,894	Cuba and Foreign W. Indies	339	52
Spain	2,393	1,049	United States of America	19,585	10,015
Gibraltar	8,373	3,145	Mexico	11	5
Italy	8,377	3,320	Brazil	5,352	2,043
Malta	4,865	1,833	Rio de la Plata	1,544	751

Turkey and Continental Greece	6,098	2,301	Peru	58	43
Morea and Greek Islands	60	20	Guernsey, Jersey, Alderney, and Man	68,482	25,154
Egypt	6,910	2,589			
Tripoli, Barbary, and Morocco	5,154	1,770			
W. Coast of Africa	30	25			
Cape of Good Hope	1,828	1,021			
Saint Helena	297	270			

The owners of the greater part of the collieries in the counties of Durham and Northumberland have entered into a mutual agreement under the denomination of 'The Limitation of the Vends,' which has continued in operation with some interruptions from the year 1771 to the present time. The object of this compact is to apportion among the different collieries the quantity to be raised and sold, according to the quality of the coal and the power of raising it, and with reference also to the probable demands of the different markets in the kingdom. The nature of the regulation was explained by Mr. Brandling to a committee of the House of Commons, in 1830, in the following terms:—

'When it is understood by the coal-owners that all the parties interested in the coal trade on the Tyne and Wear are willing to enter into an arrangement of this nature, a representative is named for each of the collieries; these representatives meet together, and from amongst them choose a committee of nine for the Tyne, and seven for the Wear. This being done, the proprietors of the best coals are called upon to name the price at which they intend to sell their coals for the succeeding twelve months; according to this price the remaining proprietors fix their prices: this being accomplished, each colliery is requested to send in a statement of the different sorts of coal they raise, and the powers of the colliery, that is, the quantity that each particular colliery could raise at full work; and upon these statements the committee, assuming an imaginary basis, fix the relative proportions as to quantity between all the collieries, which proportions are observed, whatever quantity the markets may demand. The committee then meet once a month, and according to the probable demand of the ensuing month they issue so much per 1000 to the different collieries; that is, if they give me an imaginary basis of 30,000, and my neighbour 20,000, according to the quality of our coals and our power of raising them in the monthly quantity, if they issue 100 to the 1000, I raise and sell 3000 during the month, and my neighbour 2000; but in fixing the relative quantities, if we take 800,000 chaldrons as the probable demand of the different markets for the year, if the markets should require more, an increased quantity would be given out monthly, so as to raise the annual quantity to meet the demand, were it double the original quantity assumed.'

The single circumstance upon which the committee forms its estimate of the quantity to be issued, is the price in the London market. If this has been greater during the previous month than the price fixed by the coal-owners, as already explained, added to the freight and other charges of conveyance to London, permission is given to raise a larger quantity; and on the contrary, if the price has been below a remunerative one, thus calculated, then the supply is limited till the requisite price is reached. In the agreement entered into among the owners of collieries, it is stipulated that no one without leave of the committee shall sell below the fixed price agreed on as the price to be charged by such colliery, under a penalty of 5*s.* for every chaldron so sold in excess; and every colliery giving overweight, and in that way evading the terms of the agreement, is to forfeit 2*s.* 6*d.* for every hundredweight of excess. It has been usual for each of the parties to deposit in the hands of the chairman of the committee a promissory note for a considerable amount, proportioned to the quantity allotted as the annual vend of the particular colliery, as a security for the payment of any fines that may be incurred; but during the last two years this part of the plan has not been insisted on.

This combination on the part of the coal-owners is defended on the plea that if through the free competition of the collieries a glut should be created in the market, so that any great reduction in the price should be occasioned, many of the collieries must soon cease to be worked: the effect of which would be, that those collieries which should survive the shock would then raise the price so as to indemnify themselves for the loss they may have sustained, by which means the consumer might be permanently injured. In support of this position, it is urged that in those years when the trade was free, low prices uniformly prevailed to such a degree as to involve the coal-owners in great losses, which must have ruined the weak parties, and have led to the results just described, had not the whole body felt it much for their advantage again to have recourse to the regulation of the vend. It seems however that the competition of coal-owners in other districts, when there is any failure of supply from Durham and Northumberland, would, in a considerable degree, prevent that great rise in price which has been looked for as an indemnification for previous losses. The regulation made by the committee for the year 1828 fixed the prices too high, the consequence of which was an immediate influx of coals from Scotland, Wales, and Yorkshire, into London; so that when the engagement was entered into for 1829, the price was fixed 1*s.* per chaldron lower. Had this reduction been made at first, it might have prevented the competition, which, having been once created, still exists, and has been constantly increasing. The existence of competitors, who are continually creating greater facility of communication with the great London market, must in time altogether break up the monopoly which the coal-owners of Durham and Northumberland are attempting to perpetuate. The manner and degree in which the consumers, and especially the London consumers, of the coals of Durham and Northumberland are affected by the regulation of the vend, and the impolicy to the coal-owners themselves of its continuance, may be understood from the evidence of Mr. Wood, the managing partner in an extensive colliery, given before a committee of the House of Commons, in June, 1836. Mr. Wood is of opinion, 'that the effect of the regulation is, that an inferior coal is sold at the price a better one would be supplied at in an open trade; that by abolishing the regulation the present price would be reduced 1*s.* 6*d.* per ton by the coal-owner, and many of the inferior sorts, in that case, could not be worked at a profit; there would consequently be a larger proportion of good coals, and not so much risk of admixture as at the present time; that there are no peculiarities in the coal market to prevent its adjusting itself to an open trade; no peculiarity in the application of capital in the coal trade to prevent a regular and ample supply: that an open trade would urge to economy in working; and as a case in point, he states that the manager of a colliery who in 1827 thought that the price of 24*s.* per Newcastle chaldron was the lowest at which he could supply them, now sells the same coals at 17*s.* 6*d.*; that in fact a low steady price would be ultimately better for the coal-owner than the great changes which have taken place. Under an open trade, he doubts whether there would be any profit for some time; but it would settle down to a remunerative price, as all other trades do, and the supply would then be made by those who could sell the best coals cheapest; that the best effects would follow from the most unrestricted and free exercise of every man's discretion in conducting his own trade, both at the place of purchase and of sale: and that the present prices leave an extravagant profit to the coal-owners; more than a fair remuneration.'

Another regulation affecting the coal trade from the Tyne and the Wear has been established by Act of Parliament (6 Geo. IV. c. 32), under the provisions of which every ship must be loaded in her turn; and if any colliery refuse to sell, a penalty is imposed of 100*l.*; but this regulation may be and has been evaded by the coal-owners towards ships the owners of which refuse to be bound by their regulations in the port of discharge, and the mode of evading it is to fix an exorbitant price upon their coal, which may be done although a price below the regulation is not allowed, and by this means the vessels are either brought into conformity with the regulations in the port of discharge, or forced out of the trade. The regulations here alluded to were made in June, 1834, at a meeting of the coal-factors in London, and are to this effect:—'That whenever a greater number than eighty ships reach market on any one day, the factors shall offer them for sale according to the rotation of entry; and that not more than forty of such ships shall be offered for sale on one market-day, unless the prices of best coals be 20*s.* or upwards, and in that case to be at liberty to sell such further number of ships as each factor may think proper, giving to every vessel with the same coals her fair and regular turn of sale, by which arrangements the ships will experience little or no detention, and the evil be avoided of pressing for sale at a reduced price a larger quantity of coals than the average demand of the market requires.' This rule was altered as follows in January, 1835, as far as regards the number of ships, the cargoes of which may be offered for sale in one market-day:—

'When the price of the best Sunderland coals has been on the previous market-day 21*s.* or less, the number of cargoes to be offered for sale shall be .. 40

When 21*s.* 3*d.* or 21*s.* 6*d.* 50

21*s.* 9*d.* or 22*s.* 60

22*s.* 3*d.* .. .. 70.'

Some alteration has since been made in this scale, but on the 3rd of March, 1836, it was again adopted, and has since been acted upon. Vessels loaded with coal for gas companies begin to work upon arrival, and also all vessels whose cargoes are for the use of the Government.

The effect of the regulation which fixes the minimum p[illegible] which the different qualities of coals are to be sold, is further injurious to the public, because, in order to raise the actual value more nearly to the prescribed rates, it induces the owners to screen the coal. By thus separating the least valuable part an immense waste is occasioned. The managers of collieries sell as much of the small coal as possible at the mouth of the pit, but the demand being necessarily limited to the wants of the surrounding district, a great proportion is wholly unsaleable, and is actually set on fire to clear the ground. This loss would of course be saved if the trade were made permanently free. The waste by screening is said to be always from one-fourth to one-third of the total quantity raised, and was greater even than this proportion before January, 1832, when the sale of coals by measure was abolished in and about London. Coals that are shipped to other parts, or exported to foreign countries, are less screened than those sent to London, and are consequently sold at 4*s.* to 6*s.* per chaldron cheaper.

		No. included in regulation.
The number of collieries on the Tyne, in June, 1836, was	47	41
on the Wear	17	9
on the Tees	16	9

The basis of the regulation for the vend, as settled in the preceding April, was—

		Tons.
on the Tyne 959,500	Newcastle chal., or	2,542,675
on the Wear 564,000	„	1,494,600
on the Tees 176,000	„	466,400

The coals sent from the Tees are all carried down from the collieries to the place of shipment by the Stockton and Darlington Railway. When this work was first projected, the coal-owners of Newcastle and the Wear petitioned against it on the ground that it would exonerate the owners of the collieries through or near to which it was to pass from a great portion of the expense of transport to the ship. Their opposition at that time was fruitless; but, acting upon the same principle, a meeting of the coal-owners of the Tyne, Wear, and Tees, was held at Newcastle in April, 1836, at which it was determined to oppose the progress of the Durham Junction and South Durham Railway bills, and a subscription was entered into to defray the expense of such opposition. These bills were both thrown out by the House of Lords.

The following statement shows the price per ton of the best Newcastle and Sunderland coals at the place of shipment and in London, in June and July of each year from 1813 to 1835:

	Year.	Price at Newcastle.	Price in London.
Duty 7*s.* 6*d.* per Ton.	1813	13*s.* 0*d.*	42*s.* 0*d*
	1814	13 0	44 8
	1815	13 0	39 0
	1816	13 0	34 8
	1817	13 0	31 9
	1818	13 0	32 9
	1819	13 0	30 7
	1820	13 0	30 7
	1821	12 8	32 6
	1822	11 11	30 4
	1823	12 8	33 4
Duty 4*s.* per Ton.	1824	13*s.* 0*d.*	33*s.* 4*d*
	1825	12 8	23 6
	1826	13 6	25 3
	1827	13 6	28 3
	1828	13 6	27 6
	1829	12 9	23 6
	1830	12 4	27 6
Duty repealed.	1831	12 4	22 9
	1832	12 3	19 6
	1833	10 6	15 9
	1834	10 9	19 0
	1835	11 0	20 3

The charges upon the transmission of a cargo of coals from Sunderland and upon the delivery in London, as well as the proportions in which the price paid by the dealer is divided between the coal-owner and the ship-owner, will be seen in the following account sales: viz.,

	£.	s.	d.	£	s.	d.
Night office and entry	0	4	6			
City dues on 298 tons, at 1*s.* 1*d.* per ton	16	2	10			
Metage on 293 tons, at 3*d.* (half borne by ship-owners)	1	16	7			
				18	3	11
Tret, discount, and scorage, allowed the buyer				9	6	6
Factorage, 3*d.* per ton	3	13	3			
Del Credere commission, 10*s.* per cent.	1	10	11			
				5	4	2
Insurance 160*l.*, at 15*s.* per cent.	1	4	0			
Policy duty	0	2	6			
				1	6	6
				34	1	1
Paid coal-owner for 112 chaldrons of 53 cwt., at 28*s.* 6*d.* per chaldron (10*s.* 9*d.* per ton)				159	12	0
Balance for freight to the ship on 293 tons				115	15	11
				309	9	0
293 tons sold at 21*s.* per ton, with 1½*d.* per ton metage				£309	9	0

Out of the freight, which in this case amounted to 7*s.* 11*d.* per ton, the ship-owner had to pay 9*d.* per ton delivery charges, and 1½*d.* per ton half metage.

The quantity of coals and the number of ships, including their repeated voyages, in which the same was brought into the port of London in each year from 1825 to 1835, were as follows:—

Years.	Ships.	Tons.	Years.	Ships.	Tons.
1825	6,564	1,856,606	1831	7,006	2,045,292
1826	6,810	2,040,291	1832	7,528	2,139,078
1827	6,491	1,882,321	1833	7,077	2,010,409
1828	6,750	1,960,569	1834	7,404	2,078,685
1829	6,992	2,018,975	1835	7,958	2,298,812
1830	7,108	2,079,275			

The ports from which the above shipments were made in 1835 were—

	Ships.	Tons.
Newcastle	3,897	1,266,300
Sunderland	2,182	629,544
Stockton	965	229,885
Blyth	231	65,046
Scotland	249	40,955
Wales	142	35,420
Yorkshire	251	27,394
Sundry Places	6	367
Small Coal	4	744
Culm	11	3,147
	7,958	2,298,812

COALBROOK DALE. [Coal.]

COAST, GOLD, is a part of Upper Guinea, but its boundary is not exactly determined. Geographers state that Cape Three Points (2° 30′ W. long.) constitutes its western boundary; but our navigators extend it farther west to the small river Assinee (about 5° W. long.), nearly 70 miles east of Cape Lahoo. On the east, the eastern mouth of the river Lagos (4° 20′ E. long.) is generally considered as constituting its boundary towards Benin, though the most eastern districts are often distinguished by the name of the Slave Coast. In the interior are the powerful kingdoms of the Ashantees and Dahomey, on which most of the small states along the coast are dependent.

Nearly in the centre of the coast is the English fortress of Accra. The country west of it has an undulating surface, with a small proportion of level ground: the hills are covered with shrubs and timber of small growth. The coast, though rarely high, is rocky and bold. At Accra the low country begins, and extends without interruption to the eastern boundary and still farther. It is a fertile, open, and level plain, which contains extensive savannahs covered with high grass; but in some parts it is thickly wooded with fine trees. The shores here are flat and sandy. There are no harbours along the whole line of the coast, not even for vessels of a moderate size; and as the surf is very violent, the trading vessels are obliged to anchor four or six miles from the beach. In many places landing can only be effected in calm weather; in others there are reefs, from 100 to 1000 yards from the shore, upon which the surf breaks its force, and consequently the intermediate space offers facility for landing at all times. The principal European settlements are built near such places.

The whole of this coast being near 5° N. lat., is considered one of the hottest countries on the globe; yet, according to Adams, the mean temperature is only 78°, and in the cold season the thermometer sometimes falls to 73° or 74°. Monrad also states, that on the coast it rarely attains 90°, though in the interior it reaches 94° or 95°, and in some ill-ventilated places even 100°. This comparatively low degree of heat is attributed to the circumstance that the sky is nearly always clouded. Adams says that the prevailing south-western and western winds load the atmosphere with moisture, so as to give it a haziness, which diminishes the intensity of the sun's rays and renders them more supportable than in the West Indies, where the sun shines with a brilliancy seldom seen in this part of Africa. Monrad attributes the same haziness during the eastern winds to a fine dust with which the air is filled. It is further observed, that the nights are commonly cloudless, except in the rainy season, and that the moon and the stars shine with unusual brightness in a clear blue sky.

During the Hamattan season, which begins about the middle of December and lasts to March, and is the driest and coolest part of the year, the wind blows from north-east. This wind takes the skin off, yet Monrad thinks this more healthy than the other seasons. The great rainy season begins in March and continues to the beginning of June. At first the rain pours down continually, and as the dry earth cannot absorb it quick enough, the whole country is covered with water. The rain however gradually diminishes; but during the whole season it is frequent and heavy. From June to the end of September is the warm season, which is the most unhealthy, especially the month of August, when the fogs are denser than at other times, and generate fevers. September however and October, which are the hottest months, are considered healthy. In October and November showers of rain are frequent, and hence this part of the year is called the little rainy season. Except during the Hamattan season, the winds blow from the west in the middle of the day, from eleven to three o'clock, but in the evening from south-west, and in the morning from north-west.

The climate is in general unhealthy, especially to Europeans on their arrival. Every person is attacked by a fever, which is called the seasoning, and many die of it; but when Europeans have become acclimatized, and adopt a regular manner of life, they may enjoy good health for many years. Monrad however observes, that he never saw a European who had attained the age of fifty.

This coast was formerly much resorted to by European and American vessels for slaves. When we consider that during more than a century nearly 100,000 persons were annually removed from this country as slaves, we must admit that the interior of this portion of Africa is much more populous than is commonly supposed. Many of the slaves however were brought from distant parts of the interior. At present a few vessels fetch gold and ivory: they give in exchange fire-arms, iron and iron ware, tobacco, rum, and some other articles. Many of the numerous factories and forts formerly erected on this coast for the protection of the slave-trade, have, since its abolition, been broken up and abandoned.

West of Cape Three Points the Dutch had three forts, and the English had one, Apollonia, which have all been abandoned, except the Dutch forts of Axim or S. Antony, which is the second best of the Dutch forts on this coast, and affords good landing. East of Cape Three Points is the English fort Dixcove, with a small cove under the guns of the fort, capable of sheltering a few small boats: it is the only place on the whole coast where craft can be repaired. East of it were five Dutch forts, Boutry or Boutrou, Tacorary, Succondee, Chama, and Comenda, all of which are now abandoned, as well as the English fort at Comenda.

Farther east is the Dutch fortress Elmina, or S. George della Mina, the oldest European establishment on the coast. It was erected in 1411, by the Portuguese, under the command of Don Diego d'Azambuja: the Dutch took it from the Portuguese in the beginning of the seventeenth century. It is the best fortified place on the coast, and is defended by the castle of S. Jago. The reefs along the coast form a harbour for small vessels, and the Dutch have built piers and wharfs for landing goods. The town is the only one on the coast built of stone, and the only one that is paved, but it is badly laid out, the houses being all built close together. The population is about 8000.

A few miles farther east is the principal English fortress, Cape Coast Castle, which covers a considerable space, and contains comfortable apartments for the officers, and good barracks for the privates. There are some spacious warehouses. It is built on a rock close to the sea. The town, which is behind the fortress, is considerable; but the houses are of mud, and huddled together.

East of Cape Coast Castle is the Dutch fortress of Mouree, which is now abandoned; and the next, which is the English fortress Annamabo, has a safe landing-place, and is surrounded by a town with 4000 inhabitants. The English forts Tantum and Winnebah are abandoned, and also the Dutch fortress of Berku. Near it is the English fortress of Accra, which is situated in a fine open plain several miles in length. The Dutch fortress of Crevecœur, near it, is abandoned.

East of Accra, but at no great distance from it, is the Danish fortress of Christiansburg, and farther east Friedensburg, which also belongs to the Danes. The smaller Danish forts, as Prinzerstein, have been abandoned. At a considerable distance from them, on the Slave Coast, is the last of these fortified settlements, the English fort of Whydah. In its neighbourhood the Portuguese had two small fortresses, but we do not know if they are still retained by them. The possessions of the Europeans are entirely limited to the fortresses, and their governors have no authority over the places near them, which are almost entirely inhabited by natives.

Palmas to the River Congo; Monrad's *Gemählde der Küste von Guinea.*)

COBALT. This metal is said to have been employed as early as 1540 for the purpose of giving a blue colour to glass. It was however first procured in a separate state by a Swedish chemist named Brandt, in 1733. Various processes have been recommended for obtaining this metal in a state of purity, which however is not a matter of importance for the various purposes to which it is applied. The following may perhaps answer the purpose as well as any on the small scale. Suppose the ore to contain cobalt, arsenic, copper, and nickel, dissolve it, after roasting to get rid of the greater part of the arsenic, in nitric acid; immerse a plate of iron, to precipitate the copper; then boil the solution with excess of soda, which will throw down the cobalt, nickel, and iron: dissolve this in muriatic acid, and add the solution to excess of ammonia, which will dissolve the oxides of nickel and cobalt; to the solution add potash, which will throw down the oxide of nickel, and after some days' exposure to the air, or more quickly by heat, the cobalt will be precipitated nearly or quite pure in the state of oxide. By heating it very strongly mixed with black flux it will be reduced to the metallic state. The properties of cobalt are, that it is of a reddish-grey colour, and weak metallic lustre. Its specific gravity is 7·834, according to Dr. Turner. It is not acted upon by exposure to air or water, but together they oxidize it. It fuses at a high temperature, probably rather below that of iron, and when cooling it crystallizes. It is stated that it obeys the magnet, but this is questionable.

Oxygen and Cobalt combine to form two distinctly-marked compounds; and a third, which, if not regarded as a compound of them, is a $\frac{4}{3}$ oxide. The protoxide of cobalt may be obtained by calcining the metal at a high temperature in the air, or by dissolving it in nitric acid.

Protoxide of Cobalt is obtained by dissolving the metal in nitric acid, and decomposing the solution, or that of any other salt of the metal, by carbonate of potash; the carbonate precipitated, after due washing, is to be dried, and then decomposed at a red heat without the access of air. This oxide is of an ash-grey colour; it is insoluble in water, but readily dissolved by acids, and by ammonia and its carbonate, forming with them a solution of a fine red colour. It is not soluble in the alkalis, potash or soda, or in their carbonates. When exposed to a red heat in the air, it gradually absorbs oxygen and becomes peroxide. It is the basis of all the salts of cobalt, and they usually have a red colour. It is composed of

1	equivalent of cobalt	30
1	„ oxygen	8
	equivalent	38

When a solution of nitrate of cobalt is decomposed by potash, a blue hydrate is precipitated, which absorbs oxygen from the air, and becomes of a dirty green colour, and this is stated to be a hydrate of the $\frac{4}{3}$ oxide.

Peroxide of Cobalt.—When a solution of chloride of cobalt is mixed with one of hypochlorite (or chloride) of lime, a black precipitate is obtained, which consists of peroxide of cobalt combined with two equivalents of water; the water may be expelled at a heat of about 600°, but it is difficult to expel the whole of the water, without at the same time getting rid of some of the oxygen. It does not combine with any acids; and when treated with hydrochloric acid, chloride of cobalt is formed, and chlorine gas evolved. This oxide is applied to no use, and consists of

2	equivalents of cobalt	60	or 1	30
3	„ oxygen	24	1½	12
	equivalent as peroxide	84	as sesquioxide	42

Oxide of Cobalt is procured when carbonate of cobalt is gently heated in an open fire. It is of a dark brown colour. The same oxide is obtained by heating the peroxide to redness, by which such a portion of its oxygen is expelled as reduces it to a compound of

3	equivalents of cobalt	90
4	„ oxygen	32
		122

It suffers no change by continued heat, and is therefore the most stable oxide of cobalt.

Chlorine and Cobalt may be made to unite by direct action, but the best method of forming this salt is to dissolve the protoxide of the metal in hydrochloric acid, when water and the chloride are formed. By evaporation small pink-coloured crystals are obtained, which are a hydrate. By evaporation to dryness a white scaly chloride is obtained: it is volatile at about a red heat; but when air is present, it is decomposed, chlorine is expelled, and peroxide formed. The solution when concentrated is of a deep green colour, but by dilution with water it becomes of a pale pink; when a dilute red solution is heated so as to evaporate the water, a green chloride is left, which by exposure to the air attracts moisture and becomes again colourless. This has been called Hellot's sympathetic ink.

Chloride of cobalt consists of

1	equivalent of cobalt	30
1	„ chlorine	36
	equivalent	66

The bromide, fluoride, and iodide of cobalt, are but little known, and are unimportant compounds.

Sulphur and Cobalt unite in three different proportions, forming the sulphuret, sesquisulphuret, and bisulphuret. The sulphuret may be obtained by heating to redness a mixture of oxide of cobalt and sulphur: light is disengaged during their combination, and the sulphuret which is formed fuses. It is of a yellowish-grey colour, crystalline, and has a metallic lustre. It may also be formed by passing a current of hydrosulphuric acid gas into a solution of a neutral salt of cobalt.

Sulphuret of cobalt is composed of

1	equivalent of cobalt	30
1	„ sulphur	16
	equivalent	46

Sesquisulphuret of Cobalt.—When sesquioxide of cobalt is heated in hydrosulphuric acid gas, taking care not to carry the heat to redness, sesquisulphuret of cobalt of a deep grey colour is obtained. This compound also occurs in nature. It consists of

1	equivalent of cobalt	30
1½	„ sulphur	24
	equivalent	54

Bisulphuret of Cobalt may be formed by heating the sesquioxide with three times its weight of sulphur to about the temperature at which sulphur is volatilized. When hydrochloric acid is added to the residue, it decomposes any protosulphuret which may have been formed; by a solution of potash any excess of sulphur may be dissolved, and pulverulent bisulphuret of cobalt of a black colour, but no metallic lustre, is left. Hydrochloric acid does not act upon it. It consists of

1	equivalent of cobalt	30
2	„ sulphur	32
	equivalent	62

Phosphuret of Cobalt is obtained by adding phosphorus to the ignited metal, or by heating a mixture of superphosphate of lime, oxide of cobalt, and charcoal. It is very fusible, brittle, of a bluish-white colour, and tarnishes on exposure to the air. Its exact composition has not been determined.

Selenium and Cobalt combine very readily with the production of heat; when the mass is heated to redness, the excess of selenium is expelled, it liquefies, and yields a product of a metallic appearance, a grey colour, and laminated fracture.

Cobalt and the metals combine, or at least cobalt unites with several of them, but the resulting alloys are by no means important.

Arsenic and Cobalt combine with facility; and the compound occurs in some of the ores. The arseniuret of cobalt fuses at a high temperature into a white brittle mass. It occurs in nature.

Antimony and Cobalt form a brittle alloy.

Tin and Cobalt yield a bluish-white alloy, which is somewhat ductile.

Zinc and Cobalt combine, if at all, with so great difficulty, that some chemists have denied the possibility of it.

Bismuth and Cobalt do not combine.

Lead and Cobalt unite with difficulty. The alloys in general possess the characters of the predominating metal; they are all but slightly malleable, and are harder than lead.

Mercury and Cobalt do not amalgamate.

Silver and Cobalt do not combine, and when they are melted together they separate on cooling. Still however the silver retains a little cobalt, which renders it brittle, and the cobalt a little silver, which gives it a lighter colour.

Gold and Cobalt may be combined in several proportions. Gold, with $\frac{1}{12}$ of cobalt, gives a dull yellow alloy, which is not at all malleable, nor is it when it contains only $\frac{1}{20}$, but when it amounts to only $\frac{1}{30}$ the alloy may be forged.

Platinum and Cobalt form a fusible alloy.

Acids and Cobalt form various salts, of which the protoxide is always the base. As they are not very important compounds, we shall describe only a few of them.

Nitrate of Cobalt.—This salt is easily procured by dissolving either the metal or the protoxide in dilute nitric acid. The solution is of a red colour, and by evaporation yields crystals of a deep brownish-red colour, the form of which does not appear to have been ascertained. Their taste is bitter and acrid, and they redden litmus paper; they are deliquescent, very soluble in water, and dissolved also by alcohol. When moderately heated the crystals fuse, and part with their water of crystallization; afterwards, when the heat is increased, they become blue, but the red colour returns on cooling; if still more strongly heated, the nitric acid is decomposed, and peroxide of cobalt remains. This salt is composed of

1 equivalent of	nitric acid .	54
1 „	oxide of cobalt .	38
6 „	water . .	54
	Equivalent .	146

Carbonate of Cobalt may be prepared by adding a solution of carbonate of potash to one of nitrate of cobalt, washing and drying the precipitate, which is the carbonate of cobalt. It is of a light pink colour, tasteless, unaltered by exposure to the air, and insoluble in water, but readily decomposed by acids. It consists of

1 equivalent of	carbonic acid .	22
1 „	oxide of cobalt .	38
1 „	water . .	9
	Equivalent .	69

A sesquicarbonate may probably be formed.

Sulphates of Cobalt, of which there appear to be three, viz. the neutral sulphate, bisulphate, and subsulphate. The neutral sulphate is obtained by adding carbonate of cobalt to dilute sulphuric acid; the solution is of a red colour, and by evaporation yields rhombic prismatic crystals of sulphate of cobalt, which are of a deep red colour. This salt has a sharp, bitterish, metalline taste; it is soluble in twenty-four parts of cold water, but insoluble in alcohol. When moderately heated the crystals lose their water of crystallization, and become opaque without melting, and may be made red-hot without suffering decomposition. This salt is constituted of

1 equivalent of	sulphuric acid .	40
1 „	oxide of cobalt .	38
6 „	water . .	54
	Equivalent .	132

The *Bisulphate of Cobalt* is prepared by adding acid to the neutral sulphate; the crystals are red four-sided prisms, which effloresce when exposed to the air; they contain twice as much acid and half as much water as the sulphate.

Subsulphate of Cobalt is formed when a quantity of soda or potash is added to the sulphate insufficient totally to decompose it. It is a flesh-red powder, insoluble in water; its exact composition does not appear to have been ascertained.

Phosphate of Cobalt is prepared by double decomposition. When phosphate of soda is added to sulphate of cobalt, a violet-coloured precipitate is formed, which becomes rose-coloured on drying in the air. It is insoluble in water, not decomposable by heat, but is so when charcoal is mixed with it. Its composition has not been accurately ascertained. It is used in making a pigment known by the name of Thenard's or Cobalt Blue.

The distinguishing characters of the salts of cobalt are, their red or brownish-red colour; they are not decomposed by hydrosulphuric acid, but the hydrosulphites throw down black sulphuret of cobalt; the caustic alkalis give a blue or green precipitate, ferrocyanide of potassium a greyish-green, and the alkaline carbonates a bright red. Cobalt is not precipitated by zinc.

Cobalt is very extensively employed. Its oxide gives an intense and beautiful blue colour to glass, and hence is used in colouring both glass and porcelain. Blue glass reduced to a fine powder is called *smalts* or powder blue, and is used for relieving the yellow tint of writing-paper and linen. Phosphate of cobalt has been already mentioned as entering into the composition of a blue pigment.

COBALT ORES. Cobalt is not found in the native state, and its ores, though not numerous, require a more minute examination than they have hitherto received. We shall notice those which are best known.

Bright White Cobalt or White Cobalt occurs crystalline and massive; the primary form is a cube, the planes of which are usually striated; colour silver-white; streak greyish-black; lustre metallic; hardness 5·5, yielding with difficulty to the knife, and not very frangible; specific gravity 6·3—6·5; fracture uneven; cleavage parallel to the faces of the cube; before the blowpipe on charcoal gives arsenical fumes; and tinges borax of a deep blue.

It is found in fine crystals at Tunaberg in Sweden, in Norway, Silesia, and Cornwall.

It is met with also amorphous, arborescent, botryoidal, and stalactitic.

Analysis of the crystals from Tunaberg by

	Klaproth.	Stromeyer.
Cobalt . .	44	36·7
Arsenic . .	55	49·0
Sulphur . .	00·5	5·6
		6·5
	99·5	97·8

Tin-White Cobalt or Hard White Cobalt occurs massive and crystallized in cubes and octohedrons; colour tin white, but sometimes externally tarnished; fracture fine-grained and uneven; lustre metallic; it yields with difficulty to the knife, and is hard and brittle; specific gravity variously stated, from 6·74 to 7·7; yields arsenical vapour when heated with the blowpipe, and tinges borax deep blue.

The massive is amorphous, arborescent, botryoidal, &c. The amorphous occurs in Cornwall, and the crystallized at Skutterud in Norway. Analysis of the crystals by Stromeyer:—

Cobalt . .	33·10
Arsenic . .	43·46
Iron . .	3·23
Sulphur . .	20·00
	99·79

Grey Cobalt occurs massive and crystallized; primary form a cube; colour greyish tin-white; streak greyish-black; lustre metallic; hardness 5·5; specific gravity 6·466; fracture uneven; cleavage indistinct.

The massive occurs amorphous and reticulated. It is found principally at Schneeberg in Saxony, and is used in the manufacture of smalt.

Earthy Cobalt occurs massive, amorphous, botryoidal, pulverulent, &c.; colour yellowish-brown and bluish-black; specific gravity 2—2·4; the fracture of the massive is earthy and dull, but polished by friction, and yields to the knife readily; when heated on charcoal gives an arsenical odour, and a deep blue colour with borax: it is found in Hesse, Saxony, Bohemia, and also in Cheshire and Cornwall.

Sulphuret of Cobalt occurs yellowish-white and steel-grey; streak grey; it is amorphous or botryoidal, and externally brilliant; fracture uneven. According to Hisinger it consists of

Cobalt . .	43·2
Copper . .	14·4
Iron . . .	3·53
Sulphur . .	38·50
Earthy matter . .	·33
	99·96

Arseniate of Cobalt—Cobalt Bloom—Red Cobalt—occurs fibrous, massive, and crystallized; primary form an oblique rhombic prism; colour various shades of red passing into crimson; sometimes greyish; translucent, transparent; it is soft, light, and flexible; specific gravity 2·948; the massive variety amorphous, botryoidal: structure fibrous, radiating; below the blow-pipe emits arsenical odours, and tinges borax blue: it occurs in Saxony, Bohemia, Scotland, and Cornwall, &c.

Analysis by Bucholz:—

Arsenic acid . .	37·9
Oxide of cobalt .	39·2
Water . . .	22·9
	100

Sulphate of Cobalt—Red Vitriol—is of a pale rose-red colour, and occurs investing other minerals, in small masses and in stalactites; the masses are semi-transparent and crystalline; it is soluble in water; translucent; lustre vitreous, often dull externally: it occurs among the mining heaps near Hanau and in Salzburg.

COBB. [GULL.]

COBBETT, WILLIAM, was the son of a farmer and publican at Farnham, in Surrey, where he was born, it is supposed, in 1762. He has himself related the incidents of the first portion of his life in 'The Life and Adventures of Peter Porcupine,' first published in 1796. This tract contains a most interesting account of his self-education, carried on under circumstances of difficulty, and with an ardour and steadiness of purpose that have never been surpassed. He was trained up to country work, and so employed from an early age till the autumn of 1782, when, on a visit to the neighbourhood of Portsmouth, he first beheld the sea, and the next day made an unsuccessful attempt to get employment on board a man of war. In May, the following year, on the impulse of a sudden thought which took him at Guildford fair, he came to London, and soon, by the assistance of a friend, obtained a situation as copying clerk to Mr. Holland, of Gray's Inn. After remaining here nine months, he went to Chatham, where he enlisted in a regiment of foot, which was sent out to Nova Scotia, and was eventually ordered to New Brunswick. For his excellent conduct he was made a corporal before the regiment left England; and soon after its arrival in America he was raised at once, over the heads of thirty serjeants, to the rank of serjeant-major. In New Brunswick he made his acquaintance with his future wife, then a girl of thirteen, the daughter of a serjeant-major of artillery. His own account of his courtship and marriage is, it may be fairly said, one of the most beautiful moral pictures ever drawn. Cobbett's regiment did not get back to England till the end of the year 1791, when, at his earnest request, he obtained his discharge, with a testimonial from his commanding officer, declaring that he had served honestly and faithfully for the space of eight years, and was discharged 'in consideration of his good behaviour and the services he had rendered the regiment.' He now engaged in a proceeding, of his conduct in which and the motives by which he was actuated no intelligible explanation has ever been given; we mean his bringing charges of peculation against four officers of his late regiment, and then, when a court-martial was appointed to try them, and every arrangement connected with it made in the manner he himself required, declining to come forward to prosecute. When, on the day of trial, to the surprise of all concerned, he did not make his appearance, after forty-seven witnesses named by him had been brought up from Portsmouth to London, the court, in the notion that some accident might possibly have happened to him, adjourned to the third day after, and in the mean time search was made for him in all directions; but he had crossed over to France. He remained in that country for six months, and then sailed from Hâvre de Grace for New York, where he arrived in October, 1792. About two years after this date he made his first appearance as a public writer, in an attack upon Dr. Priestley, then newly arrived in the United States from England, under the title of 'Observations on the Emigration of a Martyr to the Cause of Liberty, by Peter Porcupine.' This pamphlet attracted much notice, and was followed by a long succession of others in the same violent anti-democratic strain, and with the same signature. The whole were afterwards collected and reprinted in England in 1801, in twelve volumes octavo. The outrageous recklessness and personality of his invective, however, at length exposed him to several prosecutions for libel; and the inconveniences in which he was thus involved induced him, in June, 1800, to quit America for England. On arriving in London, he immediately started a Tory daily paper, under the title of 'The Porcupine;' but it was discontinued after an existence of only a few months. Upon this he commenced his 'Weekly Register,' which rapidly attained a large circulation, and which he kept up without the failure of a single week from its first publication till his death, a period of above thirty-three years. In the course of this time, however, it wholly changed its politics, having eventually become the most determined among the assailants of the government and the champions of democracy. The first indications of this change appeared in the course of 1803; but it was not till some years later that the conductor of the Register had completely reversed his original position. In the year 1804 two verdicts had been given against him for libel; in consequence of the first of which (for libels on the Earl of Hardwicke, then lord lieutenant of Ireland, Lord Redesdale, lord chancellor of that country, and other persons connected with the Irish government) he was fined 500*l.*; and by the second of which he was cast in 500*l.* damages to Mr. (now Lord) Plunket, then the Irish solicitor-general. In 1810 he was again tried on an information at the instance of the government for certain observations in the Register of the 10th July, 1809, on the flogging of some local militia-men at Ely; and the result was a conviction, on which he was sentenced to pay a fine of 1000*l.* to the king and to be imprisoned for two years. When he came out of prison, he set in motion a new engine for the annoyance of the administration, in the series of papers which he called his 'Twopenny Trash,' the circulation of which is said at one time to have amounted to 100,000 copies. In April, 1817, however, professedly to escape from the operation of the Six Acts, but partly also, as it is believed, in consequence of certain pecuniary embarrassments, he again visited America. While there he still continued the publication of his Register in London, the manuscript being regularly transmitted across the Atlantic. He returned to England in 1819, and soon after commenced a daily paper, which lasted only two months, involving him in further losses. Other two actions for libel immediately followed, in both of which he was cast; the damages awarded in the first (brought by Mr. Cleary) being only 40*s.*, but in the second (brought by Mr. John Wright) 1000*l.* Amidst all these troubles, neither the regularity nor the spirit of his literary labours ever relaxed. His Register was only one of many productions which his untiring and ever vigorous pen was constantly giving to the world. In 1820 he made his first attempt to get into parliament, by standing a contest for the city of Coventry, in which he was defeated. In 1826 he was again unsuccessful in a similar attempt at Preston. In 1829 and 1830 he attracted much attention by a number of political lectures which he delivered in several of the principal towns of England and Scotland. In July, 1831, he was again tried on a prosecution for libel, the charge being grounded on an article which had appeared in the Register, and which was alleged to have been published with the intent of exciting the agricultural labourers to acts of violence and to destroy property. He defended himself on this occasion in a speech of six hours; and, the jury not being able to agree in a verdict, the trial ended in his discharge.

In 1832 Cobbett was returned to the first reformed parliament as one of the members for Oldham. In the course of his parliamentary career he made several effective speeches; but his success in this new field did not, on the whole, come up to expectation, and on more than one occasion he damaged himself by those strange blunders which here and there mark every portion of his history. His death took place unexpectedly, and after a very short illness, on Thursday, the 18th of June, 1835.

A complete catalogue of Cobbett's publications would occupy more space than we can afford. Among those not already mentioned that have attracted most attention, are his 'Year's Residence in America;' his 'Emigrant's Guide;' his 'Poor Man's Friend;' his 'Cottage Economy;' his 'Village Sermons;' his 'History of the Protestant Reformation in England and Ireland;' his 'Advice to Young Men and Women;' his 'Grammar of the French Language;' his 'English Grammar,' in a Series of Letters to his Son; and his 'Rural Rides;' reprinted from the 'Register.' He also translated from the French Marten's Treatise on the 'Law of Nations;' and is understood to have been the projector and original conductor of the 'Parliamentary History,' which, for some years, bore his name.

On the subject of the intellectual character of this remarkable man, there is already a more general agreement of opinion than might have been expected, considering the vehement partisanship of the greater portion of what he has written. His mind was one of extraordinary native vigour, but apparently not well fitted by original endowment any more than by acquirement for speculations of the highest kind. Cobbett's power lay in wielding more effectively perhaps than they ever were wielded before, those weapons of controversy which tell upon what in the literal acceptation of the words may be called the common sense of mankind, that is, those feelings and capacities which nearly all men possess in contradistinction to those of a more refined and exquisite character which belong to a comparatively small number. To these higher feelings and powers he has nothing to say; they and all things that they delight in are uniformly treated by him with a scorn, real or affected, more frank and reckless certainly in its expression than they have met with from any other great writer. He cares for nothing but what is cared for by the multitude, and by the multitude, too, only of his own day, and, it may be even said, of his own country. Shakspeare, the British Museum, antiquity, posterity, America, France, Germany, are, one and all, either wholly indifferent to him, or the objects of his bitter contempt. But in his proper line he is matchless. When he has a subject that suits him, he handles it, not so much with the artificial skill of an accomplished writer, as with the perfect and inimitable natural art with which a dog picks a bone. There are many things that other men can do, which he cannot attempt; but this he can do as none but himself can or ever could do it.

COBBLE. [DIVER.]

COBI. [GOBI.]

COBI'TIS, a genus of fishes belonging to the Abdominal Malacopterygii and family Cyprinidæ. This genus includes the *loaches*, fishes generally of diminutive size, which may be distinguished by their having the head small; mouth but slightly cleft, without teeth, and furnished with barbules on the upper lip; body elongated, covered with small scales, and invested with a mucous secretion; ventral fins situated far back, dorsal fin placed above them; gill openings small; branchiostegous rays three in number.

The loach, which is common in most of our running waters, will afford a good illustration of this genus. It is about four inches in length, and of a dirty pale-yellow colour, mottled with brown; its upper lip is furnished with six barbules, one of which springs from each corner of the mouth, and the others are situated on the fore part.

Like fishes in general which have barbules, the loaches feed at the bottom of the water. The species above described spawns in March or early in April, and is very prolific.

The *spined loach* (*Cobitis tænia*, Linn.) is a far less common species than the above; its form is more compressed; the barbules are very short, and consequently less conspicuous: the principal character however consists in its having two spines, one before each eye. From this character and some other differences of minor importance, this fish, with several others having the same structure, have been separated from the true loaches, and now constitute the genus Botia of Mr. Gray.

The loaches are extremely restless during stormy weather, when they generally rise to the surface of the water, which from their restlessness is kept in constant agitation.

COBLENZ, an administrative circle or division in the province of the Lower Rhine, belonging to Prussia. It is divided by the Rhine into two unequal parts, the larger portion being on the south bank. It lies between 50° and 51° of N. lat. and 6° and 9° E. long.; it is bounded in part on the east by the grand duchy of Hesse and the duchy of Nassau, and on the south by Rhenish Bavaria, Oldenburg, and Hesse Homburg. Its area is about 2300 square miles, of which about 567,000 acres are arable land; 16,900 gardens; 123,000 meadow and pasture land; 17,300 vineyards, and 556,000 forests and woods. Coblenz contains 12 minor circles, 34 towns, 19 market-towns, 917 villages, and 463 hamlets. The population, including the military, was, in 1817, 359,204; in 1825, 399,235; and in 1831, 436,828. The number of Roman Catholics, in 1828, was 268,329; of Protestants 129,682· and Jews 6724. The surface of the country is generally hilly. The left bank of the Rhine, which is the most fertile, is traversed by a portion of the Eifel, and the Hundrachen, of which the highest summit is the Druidenstein, on the north bank of the Rhine, a basalt rock 1579 feet above the sea. The rivers of this circle are:—On the left bank of the Rhine, the Nahe, the Moselle, and the Nette; on the right, the Lahn, Sayn, and Wied. The breadth of the Rhine between Coblenz and Bingen is 1160 feet; between Coblenz and Neuwied 1230; and at Neuwied 1400. The average breadth of the Moselle, between Trarbach and Coblenz, is 595 feet.

The circle is well cultivated, and the landscape is agreeably diversified with deep valleys, fertile plains, vineyards, and naked rocks. The hills, along the banks of the Rhine and Moselle, are covered with vineyards, and the declivities with corn fields and meadows. The stock of cattle in 1831 was 12,590 horses; 169,753 horned cattle; 143,070 sheep; 11,478 goats, and 49,630 swine. The chief manufactures are woollen yarn, leather, iron and iron ware, potashes, earthenware, tobacco, mill-stones, &c.

The circle consists of 12 minor circles:—

Coblenz, cap. Coblenz, 14,724; St. Goar—Boppart, 3700; Kreuznach—Kreuznach, 7900; Simmern—Simmern, 2700; Zell—Zell, 1890; Kocheim—Kocheim, 2350; Mayen—Mayen, 3920; Adenau—No town; Ahrweiler—Ahrweiler, 2450; Neuwied—Neuwied, 5350; Altenkirchen—No town; Wetzlar—Wetzlar, 4500.

The seat of the provincial administration is at Coblenz. The ecclesiastical affairs of the Protestants are distributed among eleven superintendentships, under the provincial consistory at Coblenz; the Roman Catholics, among eleven deaconries, under the bishop of Treves.

COBLENZ, the capital of the circle of the same name, and of the whole province of the Lower Rhine, lies in a beautiful situation at the conflux of the Moselle and Rhine, whence the city obtained its antient name of Confluens, Confluentia, or Confluentes. After the conquest of Gaul by Cæsar, it came under the dominion of the Romans. Drusus erected, on the right bank of the Moselle, a castle called Confluens, which subsequently came into the possession of the Frankish monarchs. After the division of the monarchy among the sons of Lewis, in 843, Coblenz fell to the share of Lotharius, and was included in Lothringia, which province was alternately in the possession of the French and Germans till it was finally annexed to the Germanic empire by Henry I.

In 1018 the Emperor Henry II. gave this city, with its many privileges, to the archbishop of Treves; since which period Coblenz has remained attached to that archbishopric, though no longer among its temporalities. It was the occasional residence of many of the German emperors, and it was here that Conrad of Hohenstaufen was elected emperor in 1150. Here also (1338) Edward III. of England, when he laid claim to the throne of France and sought the assistance of Germany, met the Emperor Louis with other princes and several archbishops.

Coblenz was antiently fortified with walls and ramparts, traces of which still exist, and this part retained, for many centuries after it had been considerably extended, the name of Old Town. Coblenz is very irregularly built, with narrow streets and old houses. In what is still denominated 'the Old Court' stood the Roman castle, which became subsequently the palace of the Frankish monarchs, the German emperors, and the Archbishops of Treves. The 'Clement,' or New Town, which is very handsome, was built by the last electoral prince, Clement Wenceslaus of Metternich. Coblenz contains at present four Roman Catholic and two Protestant churches, and one synagogue: among the former the principal is the collegiate church of Saint Castor, built in 836, which was the place of meeting of the Council of 860, when three kings were present. The collegiate church of St. Florian, said to have been founded by the Empress Helena, has been fitted up for Protestant worship. The antient residence of the electoral princes is now the palace of justice; its chapel is built in a style of noble simplicity and adorned with paintings. There is a theatre. The castle yard is planted with trees and decorated with a pyramid 60 feet in height; the castle in the New Town has, since the French revolution, been converted into an hospital and magazines, &c. There are two bridges: one of stone, over the Moselle, 480 paces long, consisting of 14 arches, which was commenced in 1344 by Archbishop Baldwin; the other of wood, built in 1819 across the Rhine to the valley of Ehrenbreitstein, is 485 feet in length, and rests on 38 pontoons. The old Jesuits' College, now the Gymnasium, has 300 scholars, besides 200 in the elementary school attached to it; it has a considerable revenue, and a fine library formed out of the remains of the monastic libraries. There are various schools for children, a Catholic seminary for schoolmasters, a musical institution, house of industry, ladies' benevolent association, savings' bank, an orphan asylum, and various other charitable institutions. Besides the valuable town library, there are many private collections of paintings, coins, and antiquities.

Coblenz is the head-quarters of the 8th corps of the army, the residence of the superior president (ober-president) or lieutenant-governor of the province, and the seat of the provincial administration. It has a linen and a cotton manufactory and an extensive one of Japan wares; besides manufactories of furniture, carriages, and other articles. There is scarcely any wholesale business carried on, and its trade is confined to exporting the productions of the neighbouring provinces, the importation of articles of home consumption, and the transport of goods along the Rhine and Moselle. Many of the inhabitants are engaged in the cultivation of the vine.

In connection with Ehrenbreitstein, Coblenz is strongly fortified, and an important military post. The population in 1817 was, including the military, 12,238; in 1822, 13,689; in 1825, 14,333; in 1828, 14,724 (of whom 13,888 were Catholics, 576 Protestants, and 260 Jews); and, in 1831, exclusive of the military, 12,214. 50° 21′ N. lat. and 7° 30′ E. long.

COBRA CAPELLO. [Asp. Viperidæ.]

COBURG, the most southern of the independent principalities of Saxony, is bounded by the territories of Schwarzburg, Meiningen, Hildburghausen, and Bavaria; it lies between 50° 9′ and 50° 24′ N. lat., and 10° 30′ and 11° 13′ E. long., including the newly acquired territories of Königsberg and Sonnenfeld: its area is about 200 square miles, about one-fourth more than the area of Rutlandshire. It is composed of the great valley of the Itz, which is bordered on the north by the Thuringian mountains, and is traversed by the rivers Itz, Rodach, Steinach, Nasslach, Lanter, and others. Besides Coburg, properly so called, the principality now comprehends the whole of the duchy of Gotha, and the principality of Lichtenberg, which lies on the left bank of the Rhine: the whole constitutes the duchy of Saxe-Coburg-Gotha. 'Coburg Proper' belonged formerly to the counts of Henneberg; it came by marriage to the house of Saxony, whence it passed into the Ernestine line, and in 1735 to the branch of Saalfeld. The principality of Lichtenberg was added to it in 1816, and the duchy of Gotha (with the exception of some small districts) in 1826, in consequence of that house having become extinct by the death of Duke Frederic IV., when it was made over to the house of Saxe-Coburg-Saalfeld, by virtue of a family compact among the ducal-Saxon branches, in exchange for the duchy of Saalfeld and several other districts. Thus arose the present duchy of Saxe-Coburg-Gotha, containing altogether about 1000 square miles, nearly as large as Dorsetshire, and 153,700 inhabitants, which shows an increase of upwards of 8000 since the year 1826, when their numbers were 145,893; it has eleven towns, ten market-towns, 253 villages and hamlets, and about 28,100 houses.

Coburg Proper contains 32,000 inhabitants; and, including the lately acquired districts of Königsberg and Sonnenfeld, 38,000, of whom the majority are Lutherans: the Catholics (about 11,000) enjoy the free exercise of their religion. By the constitution of the 8th of August, 1821, the right of citizenship is enjoyed by natives only, who are all equal in the eye of the law, without regard to their religious profession. The legislative body consists of a single chamber, composed of six deputies from the nobility, and eleven from the magistracy, towns, and rural districts.

The climate is mild, especially in the fruitful valley of the Itz. The agricultural products are timber and fuel, grain, particularly peas, beans, hops, vegetables, &c. Iron, copper, cobalt, coals (but none of them in large quantities), limestone, sandstone, marble, alabaster, gypsum, porcelain earth, &c. are found here. The inhabitants are chiefly occupied in the manufacture of linen, woollens, and cotton, wooden toys, and the rearing of cattle. The principal articles of export are fatted cattle and grain; besides butter, leather, wood, wool, linen, and other manufactured goods. The duke takes the fifth rank among the Saxon dukes, and with them has the twelfth place at the diet, and a separate voice at the Plenum, or in the full assemblies of the diet.

Besides Coburg, the principality contains Rodach, a town on the river of the same name, with a ducal mansion, a church, 300 houses, and about 1430 inhabitants; Sonnenfeld, a market-town of about 600 inhabitants; Königsberg, upon a hill, and on the Nasslach, with a grammar-school, and about 750 inhabitants; and Neustadt, at the foot of Mount Mupp, with about 230 houses and 1400 inhabitants, having a tobacco-manufactory, hop-grounds, and some trade. [Saxe-Coburg-Gotha.]

COBURG, a bailiwick (Amt), in the principality of the same name, situated on both banks of the Itz. Exclusive of the precinct of Coburg the capital, it occupies about 66 square miles, has one market-town, 69 villages and hamlets, 1688 houses, and about 9700 inhabitants.

COBURG, the capital of the principality of the same name, in a picturesque valley on the banks of the Itz, is surrounded by walls, and, with its long suburbs, is divided into nine quarters, which have two market-places, 36 streets, 752 houses, and about 9060 inhabitants. It is far from being a handsome town; the houses are small, the streets rough, and in many places overgrown with grass. The ducal palace of Ehrenburg (burg of honour), which name it received from Charles V., has been made into a very elegant residence by the reigning duke, and has a library of 26,000 volumes, and a collection of natural history, minerals, coins, and prints. There are also the government buildings, in the Italian style of architecture; the town hall; five churches, of which Saint Maurice's church contains the ducal vault and some good monuments; the arsenal, orphan asylum, three hospitals, &c. The gymnasium, founded in 1605, by Duke John Casimir, hence called Casimirianum, has all the rights and privileges of a university. There are besides two public libraries, a collection of natural history, an observatory, with a normal school (pädagogium) attached to it; various schools, a Sunday school for mechanics and apprentices, which, in 1823, was attended by 25 mechanics and 175 apprentices; a technological society; a society of the arts and sciences, &c. There are likewise two infirmaries, a savings' bank, a ladies' benevolent association, and other charitable institutions.

The inhabitants carry on manufactures of woollens, cottons, linen, furniture, buckles, dyeing, especially the real Turkey red; gold and silver articles, chocolate, salammoniac, tools, &c. They have also a considerable trade in wool, cloth, cottons, horse-hair, flour, seeds, &c. There are several pleasure-grounds round the town, as well as many delightful rides and walks—among other places, to the ducal country seat, Rosenau, which was an old baronial castle, and has been restored in the Gothic style. Near the town are marble-polishing mills, and iron and copper works. On a lofty hill in the vicinity, which commands a beautiful prospect, is the antient fortress of Coburg, surrounded with a strong wall and five bastions. It contains many interesting remains of antiquity, arms, armour, &c. It was for some time the residence of Luther, where he delivered many of his discourses; it now contains a well-conducted house of correction, the inmates of which are employed in grinding spectacles. There are also, in the neighbourhood of Coburg, the picturesque ruins of the castles of Callenberg and Lauterberg. 50° 15′ N. lat., 10° 50′ E. long.

COCA, the dried leaf of Erythroxylon Coca, is one of those stimulating narcotics which belong to the same class with tobacco and opium, but is more remarkable than either of them in its effects upon the human system. The plant is found wild in Peru, according to Pöppig, in the environs of Cuchero, and on the stony summit of Cerro de San Cristobal. It is cultivated extensively in the mild but very moist climate of the Andes of Peru, at from 2000 to 5000 feet above the sea: in colder situations it is apt to be killed, and in warmer districts the leaf loses its flavour.

A detailed account of it is given by Pöppig and Sir William Hooker in the 'Companion to the Botanical Magazine,' whence we extract the following information. It forms a shrub from four to eight feet high, the stem covered with whitish tubercles, which appear to be formed of two curved lines set face to face. The leaves are oblong, acute at each end, three-ribbed, on short petioles, with a pair of intrapetiolary brown acute stipules. Flowers in little fascicles; peduncles sharply angled; calyx five-cleft; petals oblong, concave, wavy, with a jagged plaited membrane arising from within their base; stamens ten; styles three; fruit a one-seeded oblong drupe.

[Erythroxylon Coca.]

The effects of this drug are said to be of the most pernicious nature, exceeding even opium in the destruction of mental and bodily powers. The coca leaf is chewed by the Peruvian, mixed with finely-powdered chalk, and brings on a state of apathy and indifference to all surrounding objects, the desire for which increases so much with indulgence in it, that a confirmed coca-chewer is said never to have been reclaimed. Pöppig describes such a person in his usual graphic manner:—

'Useless for every active pursuit in life, and the slave of his passions, even more than the drunkard, he exposes himself to the greatest dangers for the sake of gratifying this propensity. As the stimulus of the coca is most fully developed when the body is exhausted with toil, or the mind with conversation, the poor victim then hastens to some retreat in a gloomy native wood, and flinging himself under a tree, remains stretched out there, heedless of night or of storms, unprotected by covering or by fire, unconscious of the floods of rain and of the tremendous winds which sweep the forest; and after yielding himself, for two or three entire days, to the occupation of chewing coca, returns home to his abode, with trembling limbs and a pallid countenance, the miserable spectacle of unnatural enjoyment. Whoever accidentally meets the *coquero* under such circumstances, and by speaking interrupts the effect of this intoxication, is sure to draw upon himself the hatred of the half-maddened creature. The man who is once seized with the passion for this practice, if placed in circumstances which favour its indulgence, is a ruined being. Many instances are related to us in Peru, where young people of the best families, by occasional visiting of the forests, have begun using the coca for the sake of passing the time away, and, acquiring a relish for it, have, from that period, been lost to civilization; as if seized by some malevolent instinct, they refuse to return to their homes; and, resisting the entreaties of their friends, who occasionally discover the haunts of these unhappy fugitives, either retire to some more distant solitude, or take the first opportunity of escaping when they have been brought back to the towns.'

The immoderate addiction of the Peruvians to the use of this drug is such that their forests have long since ceased to be able to supply their wants, and the cultivation of the plant has been carried to a very great extent, not only under the Incas, but beneath the local government of the Spaniards, who seem to have been no more able to resist the temptation of a large revenue from the monopoly of this article than European nations from the consumption of ardent spirits. It is said that in the year 1583 the government of Potosi derived a sum of not less than 500,000 pesos duros from the consumption of 90 to 100,000 baskets of the leaf. The cultivation of coca is therefore an important feature in Peruvian husbandry, and, it is added, so lucrative that a coca plantation, whose original cost and current expenses amounted to 2500 pesos duros during the first twenty months, will, at the end of ten months more, bring a clear income of 1700 pesos duros. Pöppig states that coca has now become a sort of necessary evil; that thousands of persons would be deprived of their means of existence if its consumption were put a stop to; and that the value of it in Peru and Bolivia amounts to above 2½ millions of pesos duros a year.

The exciting principle of the coca has not yet been inquired into. It is stated by Pöppig to be of so very volatile a nature that leaves only 12 months old become perfectly inert and good for nothing. 'Large heaps of the freshly-dried leaves, particularly while the warm rays of the sun are upon them, diffuse a very strong smell, resembling that of hay in which there is a quantity of *melilot*. The natives never permit strangers to sleep near them, as they would suffer violent head-aches in consequence. When kept in small portions, and after a few months, the coca loses its scent and becomes weak in proportion. The novice thinks that the grassy smell and fresh hue are as perceptible in the old state as when new, and this is to be expected with the Peruvian, who never uses it without the addition of burnt lime. Without this, which always excoriates the mouth of a stranger, the natives declare that *coca* has not *its true taste*, a flavour, by the bye, which can only be detected after a long use of it. It then tinges green the carefully-swallowed spittle, and yields an infusion of the same colour. Of the latter alone I made trial, and found that it had a flat grass-like taste, but I experienced the full power of its stimulating principles. When taken in the evening it was followed by great restlessness, loss of sleep, and generally uncomfortable sensations; while, from its exhibition in the morning, a similar effect, though to a slight degree, arose, accompanied with loss of appetite. The English physician, Dr. Archibald Smith, who has a sugar plantation near Huanuco, once, when unprovided with Chinese tea, made a trial of the coca as a substitute for it, but experienced such distressing sensations of nervous excitement that he never ventured to use it again. The Peruvian increases its effects by large doses, utter retirement, and the addition of other stimulating substances... The inordinate use of the coca speedily occasions bodily disease, and detriment to the moral powers; but still the custom may be persevered in for many years, especially if frequently intermitted, and a *coquero* sometimes attains the age of fifty, with comparatively few complaints. But the oftener the orgies are celebrated, especially in a warm and moist climate, the sooner are their destructive effects made evident. For this reason the natives of the cold and dry districts of the Andes are more addicted to the consumption of coca than those of the close forests, where, undoubtedly, other stimulants do but take its place. Weakness in the digestive organs, which, like most incurable complaints, increases continually in a greater or less degree, first attacks the unfortunate *coquero*. This complaint, which is called *opilacion*, may be trifling at the beginning, but soon attains an alarming height. Then come bilious obstructions, attended with all those thousand painful symptoms which are so much aggravated by a tropical climate. Jaundice and derangement of the nervous system follow, along with pains in the head, and such a prostration of strength that the patient speedily loses all appetite; the hue of the whites assumes a leaden colour, and a total inability to sleep ensues, which aggravates the mental depression of the unhappy individual who, spite of all his ills, cannot relinquish the use of the herb to which he owes his sufferings, but craves brandy in addition. The appetite becomes quite irregular, sometimes failing altogether, and sometimes assuming quite a wolfish voracity, especially for animal food. Thus do years of misery drag on, succeeded at length by a painful death.' (Pöppig, *Reise in Chile, &c.*, vol. ii.; Hooker, *Compan. to Bot. Mag.* i. and ii.)

COCCINE'LLA. [TRIMERA.]

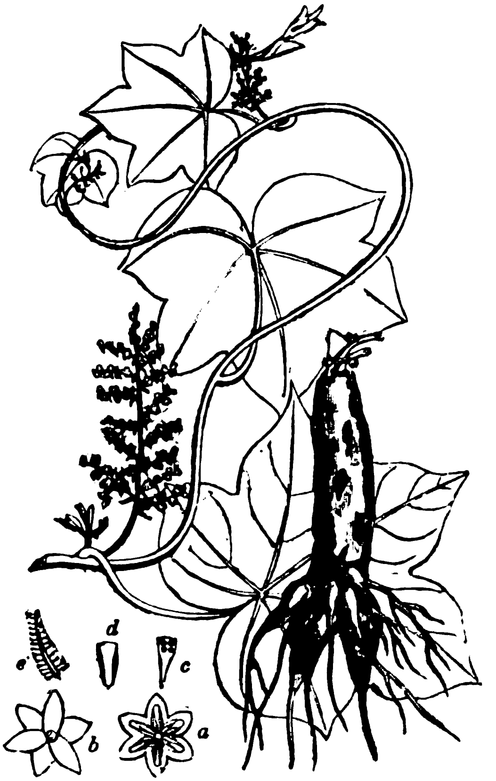
COCCOTHRAUSTES. [GROSBEAK.]

CO'CCULUS, a genus of Menispermaceous plants, consisting of climbers, whose leaves are usually more or less heartshaped, and the flowers small, and either white or pale green, in loose panicles or racemes; in most cases they are diœcious, and are always very minute. The most recent character of the genus is given by Messrs. Wight and Arnott, from whom it appears that the essential distinctions are, six sepals in two whorls, a corolla of six

petals, three or six distinct stamens, terminal two-celled anthers opening vertically; three, six, or more ovaries; and one-celled one-seeded drupes. The species are usually powerful bitter febrifuges. Cocculus crispus, a twining plant found in Sumatra and the Moluccas, with a tubercled or warted stem, is employed by the Malays for the cure of intermittent fevers. Owing to its intense bitterness and twining habit it was called *Funis felleus* by Rumf. Another plant, the Menispermum fenestratum of Roxburgh, is in great repute among the Cingalese, who slice it, steep it in water, and swallow it along with the infusion as a stomachic.

Cocculus villosus, a plant common in the hedges of Bengal, with variable downy leaves and axillary solitary female flowers, succeeded by deep purple berries the size of peas, is a species of considerable importance to the Hindoos. The juice of its ripe berries makes a good durable bluish-purple ink, according to Roxburgh, who adds some further particulars concerning its uses. 'A decoction of the fresh roots, with a few heads of long pepper, in goats' milk, is administered for rheumatic and old venereal pains; it is reckoned heating, laxative, and sudorific. The fresh leaves taste simply herbaceous; rubbed in water they thicken it into a green jelly, which is sweetened with sugar, and drank when fresh made to the quantity of half a pint twice a day, for the cure of heat of urine in gonorrhœa. If suffered to stand for a few minutes, the gelatinous or mucilaginous parts separate, contract, and float in the centre, leaving the water clear, like Madeira wine, and almost tasteless. Curry is made of the leaves, for people under a course of its roots, or jelly of the leaves.'

The species most important to Europeans is that which produces the celebrated Calumbo root, *Cocculus palmatus*, from which a valuable bitter is procured. This plant is a native of Mozambique and Oibo, abounding in the thick forests that cover the shores of those countries, and extending inland for fifteen or twenty miles. The Africans of those parts call it *Kalumb*. It has a large fleshy deep-yellow root, divided into many irregular forks or fangs, which are amputated by the collectors, cut into slices, strung on cords, and hung to dry in the shade. The stem is covered with a thick whitish-green glandular fur: the leaves are large, roundish, heartshaped, and deeply divided into from five to seven sharp-pointed lobes. The plant is now cultivated in the Isle of France.



[Cocculus palmatus.]
male flower; *b*, under side, showing calyx; *c*, stamen; *d*, petal; *e*, bractea.

The name given to this genus is that of a kind of seed imported from the East Indies under the name of *Cocculus Indicus*, possessing a powerful, bitter, poisonous principle, which, according to Goupil, exists principally in the kernel. It is found in the forests of Malabar, and when transplanted to the botanic garden, Calcutta, grew in a few years so as to extend over a large mango-tree, with a stout woody stem as thick as a man's wrist, covered with deeply cracked, spongy, ash-coloured bark. The leaves were very exactly cordate, entire, obtuse, or emarginate, of a hard texture, shining on the upper surface, and from 4 to 12 inches long, by from 3 to 8 inches broad. This plant is the *Menispermum cocculus* of Linnæus, the *Cocculus suberosus* of De Candolle; but according to Messrs. Wight and Arnott, it does not properly belong to the latter genus, having the stamens combined into a central column and no corolla. They call it *Anamirta cocculus*.

Cocculus Indicus berries are the fruit of the Cocculus suberosus (Decand.), the Menispermum Cocculus (Linn.) 'The medical jurist,' says Dr. Christison, 'should make himself well acquainted with its external characters, because, besides being occasionally used in medicine, it is a familiar poison for destroying fish, and has also been extensively used by brewers as a substitute for hops—an adulteration which is prohibited in Britain by severe statutes.' This fruit is a berried drupe, varying in size from that of a pea to that of a laurel (or bay) berry; subglobose, emarginate, dark-brown, opaque, rough, and wrinkled; the external integument, or husk, is very brittle; within is the seed or kernel, lunulate, oily, with a nauseous and intensely bitter taste. The kernel contains about one part in the hundred of picrotoxia, or menispermia, as some term it. Upon this principle its poisonous properties depend. It seems to act by exhausting the irritability of the heart, and if the dose be considerable, its fatal effects are very speedily displayed. What renders it a more redoubtable agent, is the circumstance of its leaving scarcely any trace of its presence on the coats of the stomach. Cocculus Indicus is never used internally in the practice of medicine, but an ointment formed of the powdered berries is very efficacious in some cutaneous diseases, such as Porrigo capitis, and Sycosis menti. It speedily allays the inflammatory state; but its employment requires great care. Creasote will probably supersede it in such cases.

Calumba is the root of the Cocculus palmatus, a native of the forests on the east coast of Africa, whence it is sent to Ceylon, and thence to Europe. It occurs in the form of transverse sections, the bark of which is thick and easily separable; the woody portion is spongy, of a yellow colour, and when old much perforated by worms. The odour is faintly aromatic, the taste bitter and slightly acrid. It contains much starch, a yellow azotized matter, a yellow bitter principle, traces of a volatile oil, woody fibre, salts (chiefly of lime and potassa), oxide of iron, and silex. The active principle is Calumbine, which may be obtained either by alcohol or æther. As Calumba contains nothing which can decompose the salts of iron, it may be given along with them. The powder is a good form: the infusion soon spoils, but is otherwise a very excellent form; a tincture or extract retains the virtues and keeps a long time.

Other roots are often fraudulently substituted for Calumba. Some of these are supplied by America, others by Africa. The American, which is the most common in England and the north of Europe, is the root of the Frazera Waltera (Mich.), a native of the marshes of Carolina. It may be distinguished from the true by its whiter colour, lighter texture, the presence of longitudinal pieces, and the taste being at first sweetish, and not nearly so bitter as genuine Calumba. Chemical tests further assist in discriminating them: solution of proto-sulphate or of permuriate of iron, does not trouble the tincture of the real, while it gives the false a dark green colour: the tincture of the genuine yields with tincture of galls a copious dirty grey precipitate, but the false none. The substance of the true is rendered blue by iodine, the false brown. In large doses the spurious causes vomiting, but the genuine allays that action.

Slices of bryony root are often employed to adulterate Calumba root.

Calumba acts chiefly upon the mucous membrane of the stomach, and upon the secretion and quality of the bile. It is not however without power over the nervous system, as its efficacy in allaying the vomiting of pregnancy testifies. In diarrhœa, after proper evacuants, and in bilious vomiting, it is superior to all other medicines. The vomiting and nausea of the early months of pregnancy are much alleviated by it: while the want of appetite, accompanied with general debility, of feeble children, is often removed by Calumba along with preparations of iron.

Dr. Percival states that infusion of Calumba will remove the disagreeable odour of putrefying ox-gall.

CO'CCUS. [GALLINSECTA.]

COCCUS CACTO. [COCHINEAL.]

COCCYZUS. [CUCULIDÆ.]

COCHABAMBA. [BOLIVIA.]

COCHIN-CHINA is in that part of Eastern Asia which commonly goes by the name of India without the Ganges, of which it forms the eastern portion. It extends from 8° 40′ to about 23° N. lat., and from 102° to 109° 20′ E. long. Its length from north to south is about 980 miles, but in width it varies from 100 to 300 miles. Crawfurd assigns to it an area of only 98,000 square miles; but Berghaus makes its surface one third larger, or about 147,000 square miles. This country, therefore, is about 33,000 square miles more than the British islands.

On the west it borders on the kingdom of Siam, or Shan; on the north-west on the unknown regions of Laos, or Lactho; and on the north on the Chinese provinces of Yunnan, Quang-si, and Quang-tong (Canton). To the east of it extends the sea, called by the Chinese Nan-Hay, or the Southern Sea, which here forms an extensive gulf between the northern province of Cochin-China and the island of Hai-nan, called the Gulf of Ton-kin. To the south of Cochin-China extends the southern part of the China Sea.

The character of the most northern part of the coast is not known; in our charts a great number of islands and cliffs are laid down. At 21° N. lat., or near the mouth of the river Song-ca, and farther to the south, the shores are low, and partly sandy and swampy. Between 20° and 18° N. lat., opposite the island of Hai-nan, there is said to be a number of lagunes near the low shore, connected with one another, so as to form an inland navigation of great extent. These lagunes are not inserted in our maps. Near 17° N. lat. the shores begin to be high, forming capes several hundred feet in elevation, between which large bays run deep into the land. This is the general character of the coast between 17° N. lat. and Cape James (10° 17′ N. lat.) This coast is lined with a great number of small rocky islands and cliffs, but it contains numerous safe and excellent harbours. The remainder of the coast from Cape James to the very boundary of Siam is low and mostly swampy, being formed by the alluvial deposits of the river Maekhaun, or Camboja.

Cape James is the southern extremity of an extensive mountain range, which as far as the parallel of Cape Padaran (11° 20′ N. lat.) runs north-east, and then turns to the north, in which direction it continues to 14° N. lat., whence it continues with a north-north-western course to 16° N. lat. Farther north the range is little known, and it is conjectured that it joins the high mountains in the Chinese province of Yunnan. This range occupies perhaps a hundred miles in width, and seems to consist of a number of parallel ridges. Its height, which is not ascertained, appears to be considerable. A road leads over it between the towns of Sai-gun and Phu-yen, which is described as very difficult and dangerous.

Several short offsets which branch off towards the sea cover the greatest part of the maritime districts between 10° 20′ and 17° N. lat.; some of them are known to attain the height of 4000 feet above the sea. The most remarkable of these lateral ranges is that which forms the boundary between Cochin-China and Ton-kin, in about 17° 30′. It contains a depression, forming a mountain pass, about six miles in width, which is shut in by a wall, traversed by an artificial road, which leads from Huè to Kecho, and is so well made that it is said not to be inferior to any road in Europe; the length of this artificial road is estimated at 400 or 500 miles.

The boundary between Cochin-China and the Chinese province of Quang-si is partly formed by the river Ngannan-kiang, and partly by a mountain range, which seems to be a lateral range of the Yu-ling, a mountain system of southern China. Over this range there is a pass, which constitutes the boundary line of both countries, and is also shut in by a wall, on each side of which a military post is maintained by each country.

The northern part of Cochin-China, which formerly constituted the separate kingdom of Ton-kin, comprehends an extensive plain, surrounded, except where it borders on the gulf of Ton-kin (between 19° 30′ and 21° N. lat.), by mountains, which increase in height as they recede from the sea. This plain appears to extend above 100 miles in length and width. Being very low, a great portion of it is annually inundated by the river Song-ca, which fertilizes the soil, so that two or three crops of rice are annually cut. It is by far the most fertile and populous part of the country. The valleys which run up far into the mountains are equally fertile: the greatest part of them may easily be irrigated, and the mountains themselves are rich in metals. The Song-ca, or Sang-coy, the principal river of this country, rises in the mountain-region of Yunnan in China, in two branches; the Ho-ti-kiang and Li-sien-kiang, which run nearly parallel in a south-eastern direction, till they enter Cochin-China, where they unite, and take the name of Song-ca (Great River). Before this river enters the sea it divides into numerous branches, two of which are navigable. The northern arm, which formerly was visited by large European vessels, is said now to afford access only to vessels of 200 tons burden. The southern arm is navigated by Chinese junks.

The country east of the mountain-range, between 19° 30 and 15° N. lat., consists of an alternation of small plains and intervening mountain ridges. The plains often extend nine or ten miles in width, and terminate in the west with valleys. The mountains, which do not seem to rise to a great height, are in some places bare, and in others covered with forests. In many places cultivation extends to a considerable height on their sides. Most of the plains are irrigated and well cultivated. The rivers which traverse them have a short course, but supply abundance of water for irrigation, and most of them are navigable for some miles. In some places the plains are traversed by canals.

The country which extends from Cape Avarella to the neighbourhood of Cape James may be considered as entirely covered with mountains. The rocky masses approach so close to the sea as to leave a level tract along the beach only in a few places. In its numerous indentations a few narrow valleys of small extent occasionally appear, mostly inhabited by fishermen. But though this country (formerly called Chiampa) is unfit to maintain any great population along the coast, the interior is said to contain much cultivated ground, and to be pretty well peopled.

That portion of Cochin-China which lies to the west of the mountain-range constituted till lately the principal part of the independent kingdom of Camboja. [CAMBODIA.] The southern portion, which is imperfectly known, consists, except near the boundary of Siam, of an immense plain, which appears to be formed of the alluvium of the great river by which it is traversed. The shores and the adjacent country, as far as the tide ascends, which renders the water of the river salt, are covered with trees and bushes. About thirty miles from the sea the ground begins to be cultivated, and is exceedingly fertile. In the interior a great number of fresh-water lakes and swamps are said to cover a considerable part of the plain.

Two large rivers traverse this plain. The Sai-gon or Saung, which runs through its eastern portion, has been navigated by European vessels as far up as the town of Sai-gon, but farther northward its course is not known. Its course is said to be more than a thousand miles. Towards its mouth it sends off two or more branches, which join the eastern arm of the great river of Camboja, or the Maekhaun.

The great river of Camboja, called by the Burmans Maekhaun, is probably that which in the Chinese province of Yun-nan is called Lan-thsang, and rises on the high table-land of Eastern Asia, at no great distance from the upper course of the Yang-tse-kiang. In the province of Yun-nan this river is navigable: but where it descends from that table-land and leaves the territories of China, it breaks through an extensive mountain-region, in which its course, lying between high and steep mountains, is frequently interrupted by rocky ledges and cataracts. Where its valley begins to grow wider, it is said to send off a branch to the right, which joins the Menam, or river of Siam, between 18° and 19° N. lat. Its course farther south is unknown, but it is said to send off various lateral branches, which fertilize the country through which they flow, and then re-unite with the river. About 150 miles from its mouth is the antient capital of Camboja, Pontaipret, to which European vessels ascended in the seventeenth century, but this navigation has been discontinued. Some distance below this town the river sends off to the west and south-west numerous arms, which enclose and traverse an extensive delta, that stretches out into the sea with an acute angle. Most of these arms are navigable for large river-barges during the rainy season. To make the navigation continuous through the whole year, a canal was made from it in 1820, which joins the principal river some miles south of Panompeng, the modern capital of Camboja. The three principal mouths of the Maekhaun lie on the eastern side of the delta, and are all navigable for vessels of considerable burden up to the capital of the country.

The climate of the plain of Camboja resembles that of Bengal. The rainy seasons last from the end of May or the beginning of June to September. In August the thermometer was at six o'clock in the morning 79°, at noon 82°, and at six o'clock in the evening 80°. The climate of the countries east of the mountains is similar to that of Coromandel. The mountains interrupt the clouds brought by the south-west monsoon, and accordingly the dry season prevails in that period: the north-east monsoon brings rain. The wet season sets in at the end of October, and continues until March. In the greatest summer-heat the thermometer never rises above 103°; in the greatest cold it never falls below 57°. In the countries on the shores of the Bay of Tonkin, the south-west monsoon brings the rain, and the wet season begins in May and terminates in August. The heat is occasionally very excessive, and the cold in December, January, and February, very sharp: the weather is often rendered unpleasant by heavy fogs, as in Lower Bengal. Typhons and hurricanes rage with the utmost fury in the Gulf of Tonkin and on the adjacent coasts; more southward, especially below 16° N. lat., they are rarely felt; and west of Cape James the sea and land are entirely exempt from them. They are commonly accompanied with heavy and incessant rains; and Crawfurd mentions that after a continued rain of forty-eight hours, the sea in the bay of Touron was covered with a stratum of fresh water, so that the casks of the vessels were filled with water good enough for the cattle and poultry. All the country seems to have a very healthy climate, for Europeans as well as for natives.

The iron mines of Tonkin are about six days' journey from Cachao, and the gold and silver mines about twelve days' journey, both in a western direction. The annual produce of the silver mines of Tonkin is estimated at about 213,600 ounces; that of the gold mines is unknown. All these mines are worked by Chinese: the number of miners is stated to be between 20,000 and 30,000. Cochin-China is said to have tin, which however is not worked.

Rice, which is the principal article of food, is very extensively cultivated in the plains of Tonkin and Camboja. Indian corn, earth nuts (*Arachis hypogæa*), and the *Convolvulus batatas*, are also cultivated. The sugar-cane is extensively cultivated on the coast, south of 16°; much sugar of an inferior quality is sent to China, and a small quantity to Malacca and Singapore. The true cinnamon (*Laurus Cinnamomum*) is probably indigenous; and though its bark is much thicker than that of Ceylon, it is preferred by the Chinese: from 250,000lbs. to 300,000lbs. are annually exported from Faifo.

Cotton is cultivated every where, and largely exported to China, where it fetches twenty per cent. more than that brought from Bengal. Silk is in Tonkin and Cochin-China a general object of attention with the peasantry; that of Tonkin is of better quality, but still inferior to that of China. Tea of a coarse kind is grown in the neighbourhood of the capital Hué, and called Hué tea. It is largely used by the lower classes.

The French missionary, M. de la Bissachère, states the population of Cochin-China at twenty-two millions, of which he assigns eighteen millions to Tonkin. The French officers at the court of Hué differed considerably in their statements to Crawfurd, one estimating the population at from fifteen to twenty millions, and another at ten millions. Crawfurd thinks all these numbers to be considerably exaggerated; and according to his calculation, Cochin-China contains only 5,194,000 souls. But as all authorities agree in describing the plain of Tonkin as very fertile, and extremely well cultivated and peopled, the estimate of Crawfurd seems too low

The natives call the eastern part of their country Anam, which seems to be derived from the Chinese name, which is Ngan-nan. They belong to the same race as the Chinese and Mongols. Their language is monosyllabic, and the signification of the words is, in a great measure, regulated by their accentuation. But the Anamese language is totally different from the Chinese language. The Chinese characters are only used in printing; for common purposes they use others.

The inhabitants of Camboja, who call themselves Kammer, constitute a different nation; they extend on both sides of the river Maekhaun to 15° N. lat. They do not differ from the Anamese in their physical character, but, according to Crawfurd and Dr. Leyden, they speak a different language. Klaproth however thinks that it is only a dialect of the Anamese. In manners, laws, religion, and state of civilization, they bear a nearer resemblance to the Siamese than to the inhabitants of Cochin-China Proper.

On the mountain-range live two independent nations. The Loye or Loi extend from Cape James at least as far as 15° N. lat. They once extended to the very coast, and occupied all Chiampa, but having been expelled from it, they retired into the mountain-fastnesses. Their language differs essentially both from the Anamese and Cambojan. To the north of 15° N. lat. the interior districts of the mountain-range are occupied by another independent nation, called Moi, which extends over a tract of country lying between Laos and Cochin-China, about 120 miles in length, and from 20 to 30 in breadth. They are said to be an uncivilized and inoffensive people. Very little is known of them.

The political division coincides nearly with the historical division of the country. Anam, or the eastern portion, is divided into two provinces—Tonkin the northern, and Cochin-China the southern, and the boundary-line between them, at about 19° N. lat., is nearly the same line which separated the antient kingdom of Tonkin from Cochin-China; only two small provinces have been detached from the former, and added to the latter. That portion of Camboja which has been united to Cochin-China constitutes a province by itself.

1. Tonkin or Tongking comprehends the most northern portion of Anam, or the plain which extends on both sides of the river Song-ca, and is bounded by the mountain-ranges within on all sides. It is the most fertile and most populous portion of Cochin-China, producing rice, cotton, and silk, in great abundance, and exporting extensively all these articles. Its mountains abound in gold, silver, and iron. The capital, Cachao or Cecho, called by the natives also Bakthan, is a large town with 150,000 inhabitants, situated on the banks of the Song-ca, about 80 or 90 miles from the sea. Its commerce in the products of the country is very considerable, especially with China. Hean is on the same river, about 18 miles lower down; the largest junks come up to this place.

2. Cochin-China Proper comprehends the coast from about 19° N. lat. to the neighbourhood of Cape James. The name of Cochin-China is not known to the natives, and was introduced by the Portuguese, who on their arrival in the country found that it was called Koe-chen or Cochin in order to distinguish it from Cochin on the coast of Malabar, they added China, calling it as it were Cochin of China. The natives distinguish it by the name of Dong-traoing or Dang-trong (i. e., the interior or central country); and they call Tonkin Dang-ngoai (the external country). The whole surface is covered with mountains, but towards the north the ridges are separated by wide valleys, sometimes extending to moderate plains, which however towards the south grow narrower, till in the vicinity of Cape Pataran and south of it they become narrow glens. Its principal products are sugar, silk, cinnamon, cardamoms, pepper, &c. The harbours along this coast are numerous, safe, and spacious: there is a considerable number of small towns. The capital is Hué, the metropolis of the whole country. The best and most frequented harbour is Touron or Han. To the south of it is the town of Faifo, with from 5000 to 6000 inhabitants, mostly Chinese, who carry on an active trade with their native country. The large towns of Qui-nhon, Phu-yen, and Nhatrang, are not visited by Europeans. The most southern portion of Cochin-China Proper once formed a separate country, under the name of Chiampa.

3. Camboja extends over nearly the whole of the antient

kingdom of Camboja, only one province of it, Batabang, having been united with Siam. The Chinese name of this country is Kan-phu-tche, from which Camboja is derived. As far as this country is known, it is a level formed by the alluvia of its large rivers, and very fertile and well cultivated. Its principal commercial productions are rice, areca-nuts, betel, spices, and timber. It has mines of iron. Sai-gun, on the river of the same name, may be considered as its present capital, being the seat of the provincial government. Pontaipret or Camboja, on the Maekhaun, was antiently the capital, and a very considerable town when visited by the Dutch in the seventeenth century. Nothing is known of its present condition. Panompeng, or Calompe, was at a later period the capital, and is still the residence of the nominal king of Camboja; it is in a populous and well-cultivated country. Kang-kao is about two miles from the mouth of the Kang-kao river, which forms a shallow port; it has some commerce with Singapore and the countries inhabited by the Malays. The population is about 5000.

The Cochin-Chinese have made some progress in most of the arts of civilized life. Barrow says that they excel in naval architecture, and that their row-galleys for pleasure are remarkably fine vessels; and Crawfurd thinks that the lacker-ware made in Tonkin is preferable to that of Japan. They manufacture great quantities of coarse cotton and silk cloth, but both are inferior to those brought from China. Their articles of filigree work are equal to those of the Chinese, and their vessels of cast-iron are also very good. As they are not acquainted with the art of making steel, their tools are not hard enough, and they prefer the copper tools imported by the Chinese. Fire-arms are largely imported from Europe. Their earthenware is much inferior to that of the Chinese.

The great number of excellent harbours and valuable products would seem calculated to attract foreign vessels to this country. But after the feeble attempts of some European nations to establish a regular trade were frustrated by the long internal wars of the eighteenth century, the commerce of Cochin-China was limited to its intercourse with China. Since the establishment of Singapore, however, an intercourse has been established with that colony, especially by Chinese merchants, and this trade seems to be rapidly increasing. The commerce with China is chiefly limited to the harbours of Cachao, Faifo, and Sai-gun, in Cochin-China, and to Canton, Amoy, Fu-cheou-foo, and Ning-po, in China. In 1822 there were employed in this trade, according to Crawfurd, 116 junks, of about 20,000 tons. They export from Cochin-China rice, cotton, silk, eagle-wood, spices, and some other articles; they import tea, the finer kinds of cotton and silk goods, china, and some other articles of less importance; also opium and English broad-cloth. From Singapore are imported iron, fire-arms, opium, catechu, and terra japonica. Before 1822 this commerce employed a shipping of 4000 tons, mostly Chinese junks; but it is now certainly twice if not three times as extensive. A commercial intercourse is also maintained between Faifo and Sai-gun, and Bang-kok, the capital of Siam, which however is not considerable, as only 40 or 50 small junks are engaged in it. They bring to Bang-kok silk, worked and raw, mattings for sails, &c., and take in return iron, tobacco, opium, and some European goods. (Crawfurd; Barrow; White.)

COCHINEAL is extremely rich in the finest red colouring matter, and has been long employed in scarlet dyeing, and in the manufacture of carmine. [CARMINE.]

Cochineal has been analyzed by Pelletier and Caventou, and they find that it contains—

1. A colouring matter to which they have given the name of carmine, or carminium.
2. A peculiar animal matter.
3. Fatty matter, which is soluble in æther, and consisting of stearine, oleine, and an odorous acid.
4. Phosphate of lime and of potash, chloride of potassium, and carbonate of lime; and potash combined with an organic acid.

Carminium was obtained by Pelletier and Caventou by digesting cochineal in æther; treating the residue repeatedly with boiling alcohol, allowing it to cool; treating the deposit formed with pure alcohol, and then adding a volume equal to its own of pure sulphuric æther; a deposit of carminium is thus formed.

The properties of carminium are that it is solid, uncrystallizable, of a perfect red colour, fuses at 104°; very soluble in water, slightly soluble in pure alcohol, insoluble in sulphuric æther, and in the volatile and fixed oils. Sulphuric acid, nitric and hydrochloric acids when concentrated, iodine and chlorine, destroy carminium; but when diluted, the acids render its colour brighter. Nitric acid, and also ammonia, dissolve it perfectly. Alkaline solutions added to a solution of carminium render it purple, but lime water precipitates it. If gelatinous alumina be added to a solution of carminium, these two substances combine, and the solution is completely decolourized. The lake thus obtained is of a very fine red colour, but it may be rendered crimson by heating it in the liquor in which it is formed. The greater number of saline solutions poured into a solution of carminium render it crimson; sulphate of lime, protochloride of tin, protonitrate of mercury, and submuriate of lead, precipitate it. When heated, carminium is decomposed, but unlike most animal matter, it yields no ammonia by decomposition.

The chief use of cochineal is the dyeing of scarlet; the fine colour which it yields is converted to this tint by means of chloride of tin, usually called muriate of tin, and by the dyer, tin spirits.

The insect which constitutes cochineal feeds chiefly upon the Cactus cochenillifera and C. opuntia. The female insect only is collected. Several varieties are distinguished in commerce, and have different degrees of value attached to them, dependent chiefly upon the different methods employed to kill and dry the insects. When dried they resemble small grains, scarcely so large as a pepper-corn, ovate, convex above, plane below, transversely furrowed, externally blackish-brown, but as if dusted with a white powder, light, friable, the internal substance consisting of extremely small grains, obscurely purple, but when reduced to powder, of a rich purple. Inodorous, but with a bitter-sweet acrid taste. They impart to water or alcohol by digestion an intensely red colour. The colouring principle is termed carmine.

Adulterations are effected either by mixing old insects consisting of the mere skin, or grains artificially prepared, with the genuine.

Cochineal has hitherto been employed mostly as a colouring material, either of tinctures, or of other things, the nature of which it is wished to disguise; but lately it has been stated to possess diuretic and antispasmodic powers, and to be useful in pertussis, or hooping cough. Its claim to this character requires yet to be established by further evidence. Some well-authenticated cases are recorded of the utility of a tincture of cochineal in doses of half a drachm or more twice a-day in removing or mitigating tic-doloureux, or neuralgia faciei douloureux.

COCHINEAL TRADE. (French, *Cochenille;* German, *Koschenilje;* Dutch, *Conchenilje;* Italian, *Cocciniglia;* Spanish, *Cochinilla, Grana;* Portuguese, *Cochenilha;* Russia, *Konssenel.*) Previous to the revolt of the Spanish American provinces almost all the trade in cochineal with the different markets of Europe was carried on through Spain, and chiefly through Cadiz; but since that event, and the consequent removal of the shackles which restricted the trade of Mexico, it has taken a more natural course, and the markets of consumption are supplied with cochineal either direct from the places of production, or from neighbouring stations, to which the article has found its way in the natural course of commerce. Representing a considerable value in a small bulk, cochineal is frequently used, with great convenience to merchants, as a medium for making remittances, and hence the comparatively circuitous route by which the greater part of it reaches the places of ultimate consumption. The trade in this article carried on by this country in each year from 1827 to 1835 has been:—

	Imported.	Re-Exported.	Taken for Consumption.
1827	320,722lbs.	145,756lbs.	171,325lbs.
1828	258,032	158,109	147,819
1829	288,456	153,738	127,954
1830	316,589	100,059	182,217
1831	224,371	168,329	134,222
1832	388,478	138,270	166,900
1833	359,381	130,732	178,246
1834	410,387	255,490	139,860
1835	418,320	352,023	162,596

Of the quantity imported in 1835, two thirds or 278,993lbs. came by way of the British West India Colonies; 42,754lbs. by way of the United States of America; 7218lbs. from various countries in Europe, among which Spain was not included; 2183lbs. from Cuba; and 87,172lbs. direct from the countries of production, Mexico and Guatemala. Of the quantity exported in the same year, Russia took from us 112,854lbs.; Turkey, 53,339lbs.; India, 64,178lbs.; China, 23,284lbs.; Germany, 37,992lbs.; Holland, 22,564lbs.; France, 10,315lbs.; Italy, 13,893lbs.; other European countries, 12,032lbs.; and Egypt, 1572lbs. The present price (Nov., 1836) in the London market runs, according to quality, from 6*s.* 6*d.* to 8*s.* 9*d.* per lb., exclusive of the duty: this duty was reduced in 1825 from 2*s.* 6*d.* per lb. to 4*d.* per lb. when brought from British possessions, and 1*s.* per lb. when from foreign countries: a further reduction was made in 1826 to one-half these rates, at which the duty remains at present.

COCHRANE, CAPTAIN JOHN DUNDAS, R.N., distinguished himself by travelling on foot in a very eccentric manner through France, Spain, and Portugal, and afterwards through Russia and Siberia, to the extremity of Kamtchatka. (See 'Narrative of a Pedestrian Journey through Russia and Siberian Tartary, from the Frontiers of China to the Frozen Sea and Kamtchatka,' 2 vols. 8vo. Lond., 1824.) He subsequently engaged in some of the mining companies in the New World, and died in Colombia at a time, it is said, when he was contemplating a journey on foot through the whole of South America. He tells us in his book, that in January, 1820, immediately before he began his journey to Russia, he made an offer of his services to explore the interior of Africa and the course of the Niger, but this offer was declined by Government. His object, when he left London for St. Petersburg, was to travel round the globe, as nearly as can be done by land, crossing from Northern Asia to America at Behring's Straits. 'I also,' he adds, 'determined to perform the journey on foot, for the best of all possible reasons, that my finances allowed of no other.' But at the seaport of St. Peter and St. Paul's, at the end of the Kamtchatkan peninsula, he became enamoured of a young lady of the country, and his marriage, together with some other circumstances, induced him to return to England, whither he brought his wife. The eccentricities of this most hardy and indefatigable traveller frequently approach to insanity, but his book is amusing from its oddness, and not destitute of curious information concerning countries rarely visited by Europeans.

COCK-PIT, the name for the theatre or area in which game-cocks are made to fight their battles. The sittings of his Majesty's privy council at Westminster are usually held in a room which, being the site of what was formerly the cock-pit belonging to the palace at Whitehall, still bears the name. In a man-of-war the name of cock-pit is given to a place on the lower deck, where there are subdivisions or partitions for the purser, the surgeon, and his mates.

COCK'S-COMB. [CELOSIA.]

COCK'S-FOOT GRASS, a perennial agricultural plant, the *Dactylis glomerata* of botanists, of a coarse, harsh, wiry texture, but capable of growing on the most exposed barren sandy places, and yielding a valuable food for sheep very early in the spring, before its young leaves have had time to become tough.

COCKATRICE. One of the names by which the Basilisk was known. 'Many opinions,' says Dr. Thomas Browne, in his Pseudodoxia Epidemica, 'are passant concerning the basilisk, or little king of serpents, commonly called the *Cockatrice:* some affirming, others denying, most doubting, the relations made hereof.***That such an animal there is, if we evade not the testimony of Scripture and human writers, we cannot safely deny.' This is very true, and it is equally true that the alleged generation of the basilisk, or cockatrice, and the powers attributed to it in antient times, were the most ridiculous fables.

Of basilisks, or cockatrices, there were said to be three, if not four kinds. One species burned up whatever they approached,—a sort of breathing upases, they made a desert wherever they went, for every thing animal and vegetable withered before them; a second were a kind of wandering Medusa's heads, and their look, like Vathek's eye, caused an instant horror, which was immediately followed by death;* the touch of a third caused the flesh to fall from the bones of the wretched animal with which they came in contact; and a fourth, a concentration of evil, was said to be produced from the eggs of extremely old cocks (*ova centonina*), hatched under toads or serpents. There are authors who maintain that this parentage did not belong exclusively to one kind only, but that it was the origin of the whole infernal brood.

The Greek word βασιλισκος is often translated in Latin by the word *Regulus*. When mention is made of these basilisks, or cockatrices, in the Holy Scriptures, nothing appears to occur in the sacred volume beyond words expressive of a very poisonous and deleterious serpent, intended, in the opinion of many commentators, to typify sin, misery, destruction, God's judgments, and the principle of evil, or Anti-Christ. Thus, in Psalm xci. 13, it is written 'super aspidem et basiliscum ambulabis,' which in the old quarto Bible, 'imprinted at London by Robert Barker, printer to the King's most excellent Majestie, 1615,' is translated, 'Thou shalt walke upon the lion and aspe,' and in the more modern editions, 'Thou shalt tread upon the lion and adder.' In the 'Booke of Common Prayer,' by the same printer (Robert Barker), 1613, the passage stands 'Thou shalt goe upon the lion and adder,' and so in the more modern editions. Again, Proverbs xxiii. 32, speaking of the abuse of the wine-cup, 'Mordebit ut coluber et sicut Regulus venena diffundet,' which in the old edition above alluded to is rendered, 'In the end thereof, it will bite like a serpent and hurt like a cockatrice,' and, in the modern version, 'At the last it biteth like a serpent and stingeth like an adder.' So Isaiah xiv. 29, 'Ne læteris, etc., de radice enim colubri egredietur Regulus,' etc., in the old quarto, 'Rejoyce not (thou whole Palestina) because the rod of him that did beate thee is broken: for out of y^e serpents roote shal come forth a cockatrice, and the fruit thereof shall bee a fiery flying serpent:' and lix. 5, speaking of the wicked, 'Ova aspidis rumpunt et telas aranearum texunt; qui comederit de ovis ejus morietur, et quod fructum erit, erumpet in Regulum:' in the old quarto, 'They hatch cockatrice egges, and weave the spiders webbe: he that eateth of their egges dieth, and that which is trod upon breaketh out into a serpent,' which the commentator thus explains, 'Whatsoever cometh from them is poison and bringeth death. They are profitable to no purpose.' The present edition reads, 'They hatch cockatrice eggs and weave the spider's web: he that eateth of their eggs dieth, and that which is crushed breaketh out into a viper.' Also Jeremiah viii. 17, 'Ecce ego mittam vobis serpentes Regulos, etc.,' which the same old edition renders, 'For behold I will send serpents and cockatrices among you, which will not bee charmed: and they shall sting you, saith the Lord;' which the commentator explains as follows: 'God threatneth to send the Babylonians among them, who shall utterly destroy them in such sort as by no meanes they shall escape.' The modern edition scarcely varies from the old quarto, except in the substitution of the word 'bite' for 'sting.'

These basilisks were called kings of serpents, because all other dragons and snakes, behaving like good subjects, and wisely not wishing either to be burnt up, or struck dead, or to have their flesh fall from their bones, although they were in full feast upon the most delicious prey, were supposed, the moment they heard the distant hiss of their king, to turn tail in a *sauve qui peut* style, leaving the sole enjoyment of the banquet to the royal monster.

Of the antient profane writers, Aristotle, as might be expected, says nothing about the wonders of the cockatrice but Pliny, who dearly loved a fable, mentions the basilisk more than once: thus (*Hist. Nat.* book viii. c. 21, and book xxix. c. 4) he enters at length into its deadly attributes, and records the praises with which magicians celebrate the efficacy of its blood, which was considered an admirable antidote against sorcery (veneficia). Dioscorides, Galen, Solinus, Ælian, and others, are eloquent upon basilisks, as are Avicenna, Grevinus, Scaliger, and many more.

---

* Lady Anne, in answer to Richard's observation on her eyes, says—
'Would they were basilisks to strike thee dead!'

Browne (*Pseudodoxia*) is of opinion that what 'we vulgarly call a cockatrice, and wherein (but under a different name) we intend a formal identity and adequate conception with the basilisk, is not the basilisk of the ancients, whereof such wonders are delivered. For this of ours is generally described with legs, wings, a serpentine and winding tail, and a crist or comb somewhat like a cock · but the basilisk of elder times was a proper kind of serpent, not above three palms long, as some account; and differenced from other serpents by advancing his head, and some white marks or coronary spots upon the crown; as all authentic writers have delivered.' The following is Pliny's description (*Hist. Nat.* viii. 21). After stating that the basilisk, like the beast catoblepas, slays with its eye, he proceeds:—'The Cyrenaic province produces him of the greatness of not more than twelve fingers, and remarkable for a white spot, like a diadem, on his head. He drives away all serpents by his hissing, nor does he impel his body like the rest by a multiplied flexion, but advances lofty and upright (celsus et erectus in medio). He kills the shrubs, not only by contact, but by breathing on them, scorches up the green herb, and splits the rocks: such power of evil is there in him. It was formerly believed that if killed by a spear from on horseback, the power of the poison conducted through the weapon killed not only the rider, but the horse also.' To this Lucan alludes in these lines:—

> Quid prodest miseri basiliscus cuspide Mauri
> Transactus? velox currit per tela venenum,
> Invaditque manum.'

Such a prodigy was not likely to be passed over in the legends of the saints. Accordingly we find that a good man (vir quidam justus) going to a fountain in the desert suddenly beheld a basilisk. He immediately raised his eyes to heaven, and with a pious appeal to the Deity, laid the monster dead at his feet. A somewhat similar miracle is related of the abbot St. John, who, by prayer, slew a basilisk that lay hid in the bottom of a deep well, and reduced the monks of a monastery built by him to the greatest distress for want of water. Leo IV., by a similar piety, is said to have delivered Rome from a basilisk whose breath afflicted the inhabitants with a terrible pestilence in his pontificate.

Jonston enumerates the attributes of the basilisk in silence, till he comes to its alleged power of annihilating with the eye; when he sagely remarks, 'Intuitu interimere vix crediderim, quis enim primus vidisset?' 'I would scarcely believe that it kills with its look, for who first could have seen it?' The worthy physician was not aware that those who went to hunt the basilisk of this sort, took with them a mirror which reflected back the deadly glare upon its author and, by a kind of poetical justice, slew the basilisk with its own weapon.

It is curious to observe that Browne, who treats most of the fables about the basilisk with contempt, is still unable to resist the story of its killing with the eye. We think we can trace a little of the sympathetic theory maintained by Sir Kenelm Digby and others, in the following passage: 'According to the doctrine of the antients, men still affirm that it killeth at a distance, that it poisoneth by the eye, and by priority of vision. Now that deleterious it may be at some distance, and destructive without corporal contraction, what uncertainty soever there be in the effect, there is no improbability in the relation. For if plagues or pestilential atoms have been conveyed in the air from different regions; if men at a distance have infected each other; if the shadows of some trees be noxious; if torpedoes deliver their opium at a distance, and stupify beyond themselves; we cannot reasonably deny that (besides our gross and restrained poisons, requiring contiguity unto their actions) there may proceed from subtiller seeds more agile emanations, which contemn those laws, and invade at a distance unexpected. That this venenation shooteth from the eye, and that this way a basilisk may empoison, although thus much be not agreed upon by authors, some imputing it unto the breath, others unto the bite, it is not a thing impossible. For eyes receive offensive impressions from their objects, and may have influences destructive to each other. For the visible species of things strike not our senses immaterially, but, streaming in corporal raies, do carry with them the qualities of the object from whence they flow, and the medium through which they pass. Thus, through a green or red glass, all things we behold appear of the same colours; thus, sore eyes affect those which are sound, and themselves also by reflexion, as will happen to an inflamed eye that beholds itself long in a glass; thsu is fascination made out; and thus also it is not impossible what is affirmed of this animal; the visible raies of their eyes carrying forth the subtilest portion of their poison, which, received by the eye of man or beast, infecteth first the brain and is from thence communicated unto the heart.'

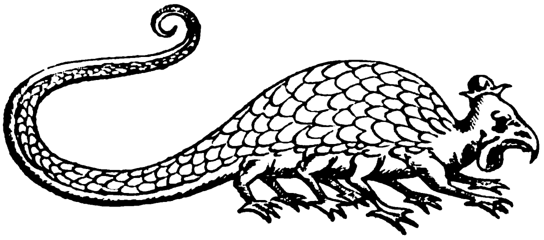
But, if the author of the 'Inquiries into Vulgar and Common Errors' here shows something of the lingering look with which most men regard received prejudices, he makes amends by declaring war against the story of the mode of the cockatrice's production. 'As for the generation,' says he, 'of the basilisk, that it proceedeth from a cock's egg hatched under a toad or serpent, it is a conceit as monstrous as the brood itself.' Jonston, who appears to regard with a proper horror most of the nefarious proceedings of the cockatrice, treats this part of the subject quite professionally. 'Quomodo,' remonstrates the sage doctor of medicine, 'formari a gallo intra ovum possit cum utero destituatur non video.' It is supposed that this idea took its rise from an Egyptian tradition concerning the ibis; 'for an opinion it was of that nation, that the ibis feeding upon serpents, that venomous food so inquinates their ovall conceptions, or eggs within their bodies, that they sometimes came forth in serpentine shapes; and therefore they alwaies brake their eggs, nor would they endure the bird to sit upon them.' (Browne.) Baptista Porta is of opinion that if a hen's egg be placed in a ditch full of serpents, corruption (tabes), arsenic, and other poisons, it will produce an animal noxious to the sight and touch: at the same time he puts the experimentalist on his guard, lest in trying to produce this animal he might (like Frankenstein) give birth to a creature that would do him a mischief.

But what was to attack this terrible and unapproachable monster? There is an old saying 'that every thing hath its enemy;' and the cockatrice quailed before the weasel. (Pliny, Solinus, and others.) The basilisk might look daggers, the weasel cared not;—in he went to the scratch. When it came to biting, the affair became more serious; but the weasel retired for a moment to eat some rue, which, of course, was the only plant the basilisks could not wither, and was always growing where they lay—returned to the charge, and never left the enemy till he was stretched dead before him. So that when men found out the den of a basilisk, they had only to turn in a weasel and the thing was done. The monster, too, as if conscious of the irregular way in which he entered the world, was supposed to have a great antipathy to a cock; and well he might, for, as soon as he heard the cock crow, he expired. This we learn from Ælian; and African travellers, consequently, carried with them the 'bird of dawning' as a specific against cockatrices.

The basilisk was of some use after death. Thus we read that its carcase was suspended in the Temple of Apollo, and in private houses as a sovereign remedy against spiders' webs, and that it was also hung up in the Temple of Diana, for which reason no swallow ever dared to enter the sacred place.

The reader will, we apprehend, by this time, have 'supped full' of absurdities, but still we can imagine his anxiety to know what a cockatrice was like. We therefore subjoin from Aldrovandus, in whose work he will find two others made out of skates (Raia), a couple of figures, one of which he seems to owe to Cardan, and the other to Grevinus. In both it will be seen that

> 'What seemed his head
> The likeness of a kingly crown had on.'



[Basiliscus in solitudine Africæ vivens.]

[Basiliscus, sive Regulus, Grevini.]

In these cuts will be seen an example of the 'Somnia portentaque Thessala,' which have vanished before the light of science. [BASILISK.]

COCKER, EDWARD. This writer, whose name is so well known in England, was born about 1631, as appears from the inscription to one of the portraits cited by Granger in his Biographical History of England. He was an engraver, and a teacher of writing and arithmetic. He is said to have published fourteen books of exercises in penmanship, some of them on silver plates. One of these is in the British Museum, namely, 'Daniel's Copy Book, &c. &c. Ingraven by Edward Cocker, Philomath. London, 1664.' The matter of these exercises in penmanship consists in great part of descriptions of hell-fire, with fiends (or something very like them) in flourishes. We have also 'Cocker's Urania, or the Scholar's Delight,' without date; and 'Cocker's Morals, or the Muses' Spring Garden,' London, 1694 (either a late edition, or a posthumous work). Cocker died before 1677, and certainly later than 1671.

The celebrated work on arithmetic was not published by Cocker himself, but as described in the following title-page:—'Cocker's Arithmetic: being a plain and familiar method, suitable to the meanest capacity for the full understanding of that incomparable art, as it is now taught by the ablest schoolmasters in City and Country. Compos'd by Edward Cocker, late practitioner in the arts of Writing, Arithmetick, and Engraving. Being that so long since promised to the world. Perused and published by John Hawkins, Writing Master near St. George's Church in Southwark, by the Author's correct copy, and commended to the world by many eminent Mathematicians and Writing Masters in and near London.' The first edition was in 1677; the fourth in 1682; the *thirty-seventh* in 1720. We have never seen the first edition: there is no copy of any edition either in the British Museum, the libraries of the Royal Society or London Institution, or (so far as the old catalogues go) in that of Sion College, or of the Faculty of Advocates at Edinburgh. We have copied the title-page from a mutilated copy of the 37th edition, being the only one we ever saw exposed for sale in London.

Cocker's Arithmetic was the first which entirely excluded all demonstration and reasoning, and confined itself to commercial questions only. This was the secret of its extensive circulation. There is no need of describing it; for so closely have nine out of ten of the subsequent school treatises been modelled upon it, that as large a proportion of our readers would be able immediately to turn to any rule in Cocker, and to guess pretty nearly what they would find there. Every method since his time has been 'according to Cocker.'

There are two other works which bear the name of Cocker, and both published by the same John Hawkins. (1.) Decimal Arithmetic, accompanied by Artificial Arithmetic (logarithms) and Algebraical Arithmetic: London, 1684 and 1685. (2.) Cocker's English Dictionary, the second edition of which bears date London, 1715. Now, since in 1677 Cocker had been dead some time, as appears by Hawkins's preface to the Arithmetic, and since Kersey's Algebra, on which Cocker's is professedly founded, was published in 1673, it will appear only just possible that Cocker could have lived to have written this work. Again, the Arithmetic was written by a person who understood Latin, as proved by apt quotations from Oughtred and Gemma Frisius: the Decimal Arithmetic is entirely without quotations, though abounding in subjects on which the author of the Arithmetic might be expected to quote. Lastly, to the preface of the Decimal Arithmetic is annexed a very clumsy attempt at a cipher, which seems utterly unmeaning, unless it be considered as wrapping up a confession of authorship. Deciphered, it is as follows:—'Amico suo amantissimo Johanni Perkes, Ptochotrophii Fohliensis in Comitatu Wigorniensi ludimagistro. Sir, if you pleas to bestow some of your spare hours in perusing the following treatise, you will then be the better able to judg how I have spent mine, and if my paines therein may be profitable to the publick I have my wish, but if not, it is not a good thing now indeed I do say so. Sir, I am your humble servant John Hawkins.' From all that precedes we are inclined to suspect that Hawkins, being in possession of Cocker's papers, and finding the Arithmetic a successful work, published others of his own in Cocker's name, perhaps with some assistance from the manuscripts of the latter.

COCKERMOUTH, a parliamentary borough and market town in the west division of the county of Cumberland. The township is in the parish of Brigham, in the ward of Allerdale above Derwent. Before the alterations effected by the Reform Act, it was co-extensive with the borough; but the borough, since the enlargement of its boundary, includes, besides the township of Cockermouth, those of Brigham, Bridekirk, Papcastle, Eaglesfield, and a portion of the township of Dovenby. The town is 25 miles S.W. from Carlisle, and 299 N.N.W. from London. Its name is derived from its position on the river Cocker, at the point of its confluence with the Derwent. The Cocker flows from Buttermere-water, and after passing through Crummock-water, divides the town of Cockermouth into two equal parts which communicate by a stone bridge. The Derwent, after it has received the Cocker, is also crossed by a handsome bridge, erected in 1822, at a cost of 3000*l*. The township occupies the site of the antient barony of Allerdale. The ruins of the castle which formerly was the baronial seat of the lords of Allerdale, and now the property of the earl of Egremont, stand on the brow of a bold eminence near the confluence of the rivers. It is supposed to have been erected shortly after the Conquest, though the Norman architecture of the remaining walls, which are of prodigious thickness, appears to be of the fourteenth century. The area enclosed by the outer walls consists of two courts. Beneath the gateway between them are two deep and vaulted dungeons capable of containing 100 prisoners: and under a building in the larger court is a spacious chamber with a vaulted roof supported in the centre by a single octagonal pillar. Lysons, in their 'Magna Britannia,' give a detailed description and a drawing of this castle (vol. Cumberland, p. 44. See also Brayley and Britton's *Beauties of England*). It was occupied by the parliament army during the civil war in 1648, and sustained a month's siege by the royalists. Since that time it has gradually been decaying, and is now habitable only in a small part. Among the antiquities which have been found, is a font of green-coloured stone, inscribed with Runic and Saxon characters. It is also worthy of remark that to the north of the town is a tumulus called Foot Hill, and to the west the rampart and ditch of a Roman camp. Cockermouth is pleasantly situated in an agricultural district, and has a promenade a mile in length on the banks of the Derwent, but the streets in some parts are narrow and confined. It is recorded that the plague in 1677 was fatal to nearly 200 of its inhabitants. The number of houses in 1834 was 1002. They are chiefly of stone, with roofs of slate, but only a few are of the better class. The town is well supplied with water, but the streets are deficient in lights and foot-pavements, and the general appearance of the place exhibits no disposition for improvement. The town-house, called Moot Hall, is the only building worthy of particular notice.

The population in 1831 was 4536, of whom 2111 were males, and 2425 females. There were then 128 families employed in agriculture, and 623 families employed in trade, manufactures, and manual labour. The population of the borough, enlarged as stated above, is 6022. Cotton, linen, and woollen fabrics are manufactured; also hats, hosiery, and paper with the tanning and dressing of leather.

The elective franchise was first granted to the borough in the reign of Edward I.; but it appears not to have been exercised until it was renewed under Charles II. It continues to send, as formerly, two representatives to parliament, and it is the place where the court of election is held for the western division of the county of Cumberland. The quarter sessions are alternately held here and at Carlisle. There is a free school which was founded in the time of Charles II., and over the school-house a parochial public library consisting of 500 volumes. There is also a subscription library, a dispensary, a Sunday-school, and four friendly societies. The living is a chapelry, in the diocese of Chester, and places of worship are established by several sects of dissenters. The Rev. John Fell, who wrote on the 'Demoniacs,' 'Rowley's Poems,' &c., was a native of Cockermouth. On the first Monday in May, and on the 10th of October, there are fairs, chiefly for horned cattle and horses. (*Boundary Report*, part i., p. 95; Lysons's *Mag. Brit.*; *Population Report*, 1831.)

COCKLE. [CONCHACEA.]

COCKNEY, a term of contempt for a Londoner, borrowed originally from the kitchen. A cook, in the base Latinity, was called *coquinator* and *coquinarius*, from either of which Cokenay, as Chaucer uses it in the 'Reve's Tale,' might be derived

> 'And when this jape is told another day,
> I shall be halden a daffe or a cokenay.'

In some rhymes ascribed to Hugh Bigot, which Camden published in his 'Britannia,' London itself appears to be alluded to under the name of Cockeney

> 'Were I in my castle of Bungey,
> Upon the river Waveney,
> I would ne care for the king of Cockeney.

The author, says Tyrwhitt, in calling London Cockeney, might possibly allude to that imaginary country of idleness and luxury which was antiently known by the name of *Cokaigne*, or *Cocagne*; a name which Hickes (*Gram. Anglo-Sax.*, p. 231) has shown likewise to be derived from *coquina*. Boileau, in his 'Satires,' speaks as if the French metropolis had the same appellation bestowed upon it (*Sat.* vi.)

> 'Paris est pour un riche un pais de Cocagne.

The name of the festival of *La Cocagna* at Naples, described by Keysler, vol. ii. p. 369, appears to have the same origin.

(Tyrwhitt's *Notes on Chaucer*, 4th edit. vol. ii. p. 437; Brand's *Popular Antiquities*, vol. i. p. 65; Nares's *Glossary, in voce*.)

COCKROACH, the common name for the Blatta orientalis. [BLATTIDÆ.]

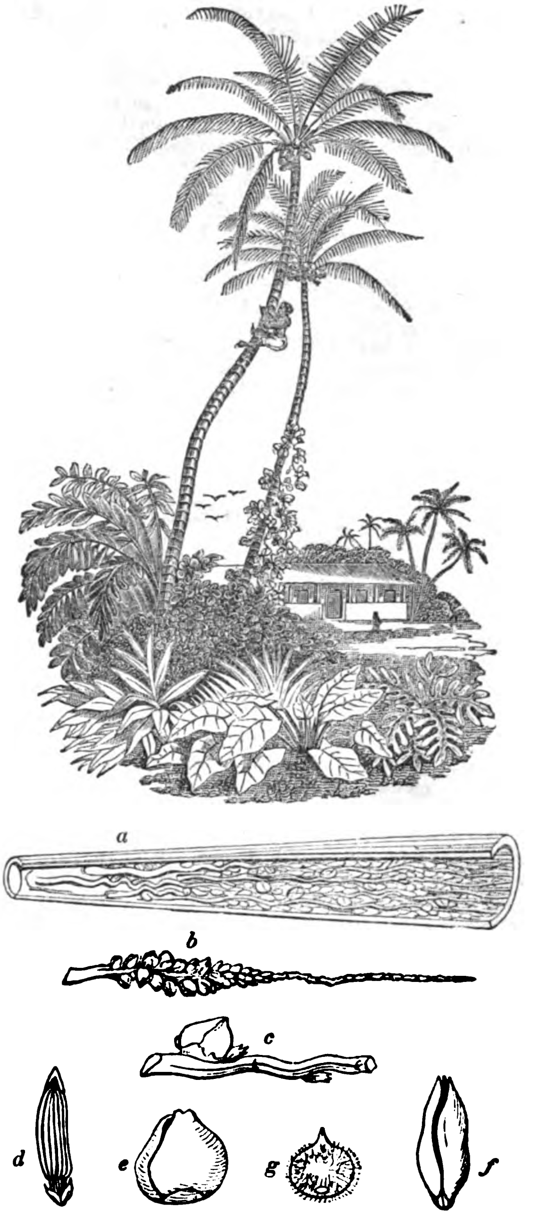
COCKSCOMB. [CELOSIA.]

COCOA-NUT. [COCOS.]

COCOA-PLUM, the fruit of *Chrysobalanus Icaco*.

COCOON. [PUPA.]

COCOS, a genus of palms thus defined by Von Martius. Both male and female flowers on the same spadix. Spathe simple; flowers sessile. Males: calyx three-leaved; corolla of three petals; stamens six; a rudiment of a pistil. Females: three sepals and three petals rolled together; ovary three-celled; stigmas three, sessile; drupe fibrous; putamen with three pores at the base; albumen homogeneous, hollow; embryo next one of the pores at the base; stems either lofty or middle-sized, slender, ringed, or crowned by the bases of the petioles, with a pale fibrous wood; leaves pinnated; the pinnæ lanceolate or linear; flowers pale yellow; drupes brown, green, or orange colour, rather dry. The genus contains several species, the most interesting of which is the common cocoa-nut, *Cocos nucifera*.



Cocos nucifera.]

a, lower portion of the spathe opened; *b*, branchlet, with female flowers—the males on the upper end dropped off; *c*, female flower; *d*, stamens *e*, female corolla; *f*, male corolla; *g*, germen.

This plant is found all over the tropical parts of the world, especially in the vicinity of the sea, growing within reach of salt water, and establishing itself upon reefs and sandbanks as soon as they emerge from the ocean. Its principal range is said by Mr. Marshall to be between the equator and the 25th parallel of latitude, and in the equinoctial zone to an altitude of about 2900 feet. Its great importance to man has caused it to be cultivated wherever the climate is favourable to its growth; and accordingly it is sometimes found occupying extensive tracts to the exclusion of all other trees: the whole Brazilian coast from the river San Francisco to the bar of Mamanguape, a distance of 280 miles, is, with few breaks, thus occupied; and it was estimated that in the year 1813 no fewer than 10,000,000 trees were growing on the south-west coast of Ceylon.

The cocoa-nut palm rises like a slender column to from 60 to 90 feet in height; its stem is of a soft fibrous nature, and is marked on the outside by rings produced by the fall of its leaves; two such leaves are said to drop off annually, and consequently the age of an individual is equal to half the number of the annular scars of its stem. About a dozen or fifteen leaves, each from 12 to 14 feet long, crown the summit of the stem; and as these are not inaptly compared to gigantic ostrich feathers, they give the plant the air of an enormous tuft of vegetable plumes. A reticulated substance resembling coarse cloth envelops the base of each leaf-stalk, but falls off before the leaf is full grown. The flowers proceed from within a large pointed spathe, which always opens on the under side. In wet seasons the tree blossoms every five or six weeks, so that there are generally fresh flowers and ripe nuts on the tree at the same time; there are commonly from five to fifteen nuts in a bunch; and in good soils a tree may produce from eight to twelve bunches, or from 80 to 100 nuts annually.

In hot countries the uses to which the cocoa-nut tree is applicable are innumerable. The roots are chewed in place of the areca-nut; gutters, drums, and the posts of huts are formed from the trunk; the young buds are a delicate vegetable; shade is furnished by the leaves when growing, and after separation from the tree their large size and hard texture render them invaluable as thatch for cottages; they are moreover manufactured into baskets, buckets, lanterns, articles of head-dress, and even books, upon which writing is traced with an iron stylus. Their ashes yield potash in abundance; their midrib forms oars; and brushes are formed by bruising the end of a leaf with a portion of the midrib adhering to it. From the juice of the stem, a kind of palm wine, and subsequently an ardent spirit, are prepared; the farinaceous matter contained in the stem is a good substitute for sago; and a coarse dark-coloured sugar, called jagghery, is obtained from inspissating the sap. This jagghery, mixed with lime, forms a powerful cement, which resists moisture, endures great solar heat, and will take a fine polish. The ripe fruit is a wholesome food, and the milk it contains a grateful cooling beverage; indeed these together constitute the principal sustenance of the poorer Indians in many countries. The fibrous bark is used to polish furniture, as brushes, and to form a valuable elastic cordage, called *coir;* the fibrous matter is also employed to stuff mattresses. The shell is manufactured into drinking-vessels and vessels of measure; and finally, the albumen, or white solid matter contained within the shell, yields by pressure or decoction an excellent oil; the former is the method usually employed. This oil is not only employed for burning, but in the manufacture of torches, and in the composition of pharmaceutical preparations; and mixed with dammer (the resin of *Shorea robusta*) it forms the substance used in India for paying the seams of boats and ships.

The name cocoa seems to be a contraction of the Portuguese ma*coco* or macaco, a monkey, and to have been given from the resemblance between the end of the shell, where the three black scars are, and the face of a monkey. These three scars indicate the places through which the three embryos of the fruit, if equally and completely developed, would be protruded. But as out of the three ovules originally formed in the cocoa-nut two are constantly abortive, it happens that one only of the scars has to fulfil its destined purpose: that one is known by its being easily pierced by a pin; the others are as hard as the remainder of the shell. It is immediately below the soft scar that the embryo of the cocoa-nut is formed, and the use of the scar is to allow of a passage through the shell of the nut for the germinating embryo, which, without this wise contrivance, would be unable to pierce the hard case in which it is confined.

Cocoa-nuts are brought to Europe as wedges to set fast the casks and other round packages in the cargo of vessels; their freight therefore costs nothing.

COCUMI'GLIA, the name of a kind of plum (Prunus Cocumilia) found wild in Calabria, and having the reputation of being a powerful febrifuge. It is described as bearing a general resemblance to the cultivated plum, but with short double peduncles, elliptical-obovate leaves, which are smooth, crenelled, and tapering to each end, the crenelling and the petioles covered with deciduous glands, and with ovate-oblong fruit of a dull tawny yellow colour, with a slightly incurved point, and an austere astringent flavour. It is abundant about Sile, and on the mountains which overlook Monteleone, Staiti, Cotrone, and Mesoraca, on the sides exposed to the sea, as far as the height of about 3000 feet. The bark of this species is in extensive use for the cure of the intermittent fevers of Calabria, both in private practice and in the military hospitals, where it is preferred to cinchona. The bark of the root is principally employed either in decoction or extract; and its valuable qualities are attested by Savaresi, Polizzi, Tenore, and other Nea[illegible]n physicians. The medicinal properties of the Cocumiglia are said to have been discovered by a noble citizen of Monteleone, who annually caused a considerable quantity of the extract to be prepared and distributed among the Calabrian peasantry. It is worthy of notice that febrifugal properties are assigned by Mérat to the bark of the common sloe; and, considering the very close affinity between the cocumiglia, the sloe, the bullace, and the common cultivated plum, it is highly probable that similar qualities are possessed by all of them. The bark should be collected in the months of November, December, or January.

CODDY MODDY, a gull in its first year's plumage. (Montagu.)

CODE, CODEX. Before the use of more convenient materials, wooden tablets were employed by the antients for writing on. Such a written tablet was called codex, of which codicillus is a diminutive. First they wrote by making notches or indents in these tablets, but afterwards they covered them with wax, and used a style to write with.

The notion of the word was then extended, and it has now several significations. 1. Codex may denote any handwriting on parchment or paper. 2. The diminutive codicillus signifies a less solemn last will or testament. [CODICILLUS.] 3. A collection of laws is also called codex, or code in modern languages, as in English and French. In this sense the word is now most commonly used. There are several kinds of codes. A code may be made by merely collecting and arranging in a chronological or systematical order the existing laws of a state, which have been made at various times by the sovereign power. Such a collection is either made by public authority, as was the case with the Codex Theodosianus [THEODOSIAN CODE] and Codex Justinianeus [JUSTINIAN CODE AND ROMAN LAW], or by private individuals, as is the case with the Codex Gregorianus and Hermogenianus. The Germans call collections of old German laws, made in the middle ages, 'Rechts bücher' (books of rights). Very different from a mere compilation of existing laws is a code (in German *Gesetzbuch*, book of laws), by which the legislative power sets up a new system of laws. A mere arrangement and classification of existing laws is more properly called a Digest. If to this classification and arrangement selection be superadded, it would still be properly only a Digest. A code, though it may adopt many existing laws and customs, is now generally used to express a complete new system, founded on new fundamental principles; such principles, for instance, as are set forth in Bentham's 'Leading Principles of a Constitutional Code for any State.' In England, for example, if it were proposed to make a code, it might be found useful or necessary to modify the law of tenures, or to abolish certain kinds of tenures, such as customary tenures; and also to provide positive rules for numerous cases that are still either totally unprovided for or left doubtful by conflicting decisions, or regarded as of little authority.

CODEIA, an alkali existing in OPIUM.

CO'DES, LES CINQ, is the name given to several compilations of laws, civil and criminal, made in France after the revolution, and under Bonaparte's administration. They consist of the Code Civil, Code de Procédure Civile, Code de Commerce, Code d'Instruction Criminelle, and Code Pénal. To these has been added the Code Forestier, or regulations concerning the woods and forests, promulgated under Charles X. in 1827. Hence the whole collection is sometimes called 'Les Six Codes.' But even this number is not correct, as there are also a Code de la Conscription and a Code Militaire, both published under Napoleon. These two last are treated under CONSCRIPTION and MUTINY ACT.

Civil Code.—The old laws of the French monarchy were founded partly on the Roman law, partly on the numerous different customs of the various provinces, and partly on the ordinances of the kings. Having been abrogated at the revolution, several attempts were made, by Cambacères among others, to form a code of laws in accordance with the altered state of society; but the fury of the internal factions, the cares of foreign war, and the frequent changes of rulers, prevented any calm deliberation on the subject during the first years of the revolution. After Bonaparte became first consul, he appointed, in 1800, a commission, consisting of Tronchet, president of the Court of Cassation, Bigot de Préameneu, Portalis, and Malleville, to draw up a project of a civil code. The project was printed early in 1801, and copies were sent to the different courts of France for their observations and suggestions. The observations and suggestions were likewise printed, and the whole was then laid before the section of legislation of the council of state, consisting of Boulay, Berlier, Emmery, Portalis, Roederer, Real, and Thibaudeau. Bonaparte himself, and Cambacérès, his colleague in the consulship, took an active part in the debates. The various heads of the code were successively discussed, after which they were laid before the tribunate, where some of the provisions met with considerable opposition. The code however passed at length both the tribunate and the legislative body, and was promulgated in 1804 as the civil law of France, 'Code Civil des Français.' Under the Empire its name was changed into that of Code Napoléon, by which it is still often designated, though it has now officially resumed its original title of Code Civil. This code affects to define the civil rights of Frenchmen, and their legal relations to each other, and to society at large. In its general arrangement and distribution it resembles the Institutions of Justinian; like them, it has adopted the great distinction of laws concerning the person, and laws concerning property. It consists of three books, divided into titles or heads, each of which is subdivided into chapters and sections. Book I., in eleven heads, treats of persons; specifies their civil rights; regulates the means by which their rights are certified; prescribes the mode of registering births, marriages, and deaths; defines the conditions constituting the legal domicile of each individual; and provides for cases of absence. It then treats of marriage as a civil contract, the forms required, the obligations resulting from it, and lastly, of separation and divorce. The articles concerning divorce, which gave rise to much debate and opposition at the time, have been repealed since the Restoration, and separation alone is now allowed. The code proceeds to treat of the relations of father and son, of legitimate and natural children, of adoption and guardianship, and of paternal power. Under this last head the French code, without adopting the rigid principle of the old Roman law in its full extent, gives to a father the right of imprisoning his son during his minority for a term not exceeding six months, by a petition to that effect, addressed to the president of the local court, who, after consulting with the king's attorney, may give the order of arrest without any other judicial forms being required. The remaining heads treat of minority and emancipation; majority, which is fixed, for both sexes, at 21 years complete; of interdiction, and the council of trustees appointed in certain cases to administer the property of a man who is incapable of doing it himself. Book II. treats of property and its various kinds and modifications. The 1st head draws the distinction between *meubles* and *immeubles*, or personal and real property; though these two words do not exactly express, to an English lawyer, the distinction between *meubles* and *immeubles*. The 2nd defines the different rights of ownership. The 3rd treats of usufruct, use, and habitation. The 4th concerns rural servitudes, the *prædiorum servitutes* of the Roman law, excluding all former personal servitudes which were abrogated at the revolution. Book III. treats of the various modes by which property is legally acquired, such as inheritance, donation inter vivos, and wills or testaments. A father can dispose by testament of one-half of his property if he has but one legitimate child, of one-third only if he has two, and of one-fourth if he has three or more. The law then proceeds to treat of contracts or conventional obligations, specifying the modes of proving them by written documents, official or private, or by witness, or lastly by presumption. The 5th head treats of the marriage contract, and the respective rights of husband and wife according to the various stipulations, either by community or separation of property, or by dowry. Next come the heads of sales, exchanges, leases, partnerships, loans, deposits, and sequestration. The 12th head concerns the contracts called aléatoires, which depend in a great measure upon chance, such as insurance, annuities, &c. The law treats next of power of attorney, of bail and security, and of amicable compromise. The 18th head concerns privileged creditors and mortgages. This subject is very elaborately treated, and has been much extolled as a very valuable part of the Civil Code, on account of the security which it gives to property by means of the public offices for registering mortgages, of which there is one in every district. The registration of mortgages has been adopted in most of the Italian states, and other countries besides France; but even this system is not considered perfect, because there is no obligation to register every sale or transmission of property, nor the servitudes affecting property and because the French code admits of sales by private contract, and of mortgages in favour of minors or wives, even without registration. In this particular the Austrian code is considered superior, because it enforces the registration of every transmission of property, and of every burthen or servitude, on the book of census, or cadasto, for each district. (See also Grenier, *Traité des Hypothèques*, 1824: *Introduction.*) The nineteenth head of the French civil code treats of expropriation or seizing, or selling off by execution; and the twentieth, or last, of prescription.

Much has been written on the merits and defects of this celebrated code. In order to judge of its value, we ought to read the reports of the discussions in the council of state by the most distinguished jurists of France. (Locré, *Esprit du Code Napoléon tiré de la Discussion*, 6 vols., 8vo., 1805; and Malleville, *Analyse raisonnée de la Discussion du Code Civil au Conseil d'État*, 4 vols., 8vo., 1807.) On the other side, several distinguished German jurists have pointed out its imperfections. (Savigny, *On the Aptitude of our Age for Legislation*, translated from the German by a barrister of Lincoln's Inn; Rehberg, *über den Code Napoleon*, Hanover, 1814; Thibaut, Schmidt, &c.) With regard to the part which Bonaparte took in its discussion, not of course as a professional man, but as a quick-sighted observer and critic, a lively account is given in Thibaudeau's *Mémoires sur le Consulat*, in which his own original expressions are preserved.

Code de Procédure Civile.—The Code Civil having determined what was law, it remained to prescribe the forms of civil process and the practice and rules of the courts. The Code de Procédure is divided into two parts. The first part treats of the various courts: 1st. Of the justices of peace and their jurisdiction. There are about 2840 of these magistrates in France, who decide petty cases not exceeding 300 francs, and also act as conciliators between parties at variance, who are not allowed to plead before a court without having first appeared before the juge de paix. 2nd. Of the process before the tribunaux de première instance, which try civil cases without jury. There is one of these courts in every arrondissement. 3rd. Of appeals to the Cours Royales, of which there are 27 established in the larger towns, each having several departments under its jurisdiction; these courts try cases by jury. 4th. Of various modes of judgment. 5th. Of the execution of judgments. The second part treats of the various processes for the recovery of property, separation between husband and wife, interdiction and cession of property by an insolvent debtor. Foreigners are excluded from the benefit of the *cessio bonorum*. The code then passes to the subject of inheritance, the affixing of seals, taking inventories, &c. The last book treats of arbitration. The Code de Procédure was in great measure founded on the ordonnance of 1667 of Louis XIV., with considerable ameliorations. It was framed by a commission appointed in 1800, then discussed in the council of state and the tribunate, and lastly passed by the legislative body. It was put in force in January, 1807. 'An orator of the government, using the licence of flattery, said in his report that the principal difficulties in definitively settling the code had been cleared up by the emperor himself, who had adapted the forms to the present wants of society. The fact is that Napoleon took no part in the discussion of this code, which was conducted during his journeys to Italy and to the camp of Boulogne, and during the campaign of Austerlitz. Besides, it was a dry and unattractive subject, very unlike that of the Civil Code, and the emperor finding himself a complete novice in it, gave it up entirely to professional lawyers. His general views would have been to simplify the forms, and to check the sources of chicanery, but he was not heeded. One of his ideas was that solicitors and counsellors should not be paid unless they gained the cause. The routine lawyers, however, had too much influence in the work.' (Thibaudeau, *Histoire de France sous Napoléon*, vol. v., p. 124-5.) The government afterwards published a table of the expenses, duties, fees, &c. attending civil process. The table, which is given at the end of the collection of the codes, presents a formidable appearance by the multiplicity and minuteness of the charges which attend every step of legal proceedings. Indeed this is the principal reproach made against the Code de Procédure, the multiplicity of formalities, written acts, registrations, stamps, &c. Another objection is, that in actions in which the state is concerned, it has advantages over private parties. But the publicity of the discussions, the security to all civil proceedings by means of registration, the well-defined authority of the various courts, the independence of the judges, and the establishment of local courts all over the country, and above all the institution of the supreme Court of Cassation—these are essential and lasting advantages.

The *Code de Commerce* was promulgated in January, 1808. It was founded in some measure upon the ordonnances of 1673-81 of Louis XIV. Next to the Civil Code, it is considered the best part of French legislation. The institution of the commercial tribunals has been of great advantage to France, and has been adopted in other countries. These courts, of which there are 213, consist of a president and two or more judges, all chosen by the merchants among themselves, and for a time; they are not paid, but the greffier or registrar receives a salary. The Code de Commerce consists of four books: the first treats of commerce in general, of the various descriptions of commercial men, of the keeping of books, of companies and partnerships, of brokers, commissioners, carriers, &c.; the second treats of maritime commerce, shipping, insurances, &c.; the third concerns bankruptcies; and the fourth treats of the commercial tribunals, their jurisdiction and proceedings. Appeals for cases above 1000 francs lie to the cour royale of the district.

Code d'Instruction Criminelle.—The criminal laws of France under the old monarchy were defective, confused, and arbitrary. There was no penal code, but there were various ordonnances for the punishment of particular offences. The ordonnance of Louis XIV. for regulating proceedings in criminal cases introduced something like uniformity, but it maintained torture, which in some cases was repeated, secret trial, and other anomalies of the legislation of the middle ages. Torture was abolished by Louis XVI. The first National Assembly in 1791 recast the criminal legislation, introduced the jury, and remodelled the criminal courts after those of England. Then came the reign of terror, with its exceptional laws, or rather no laws at all but the caprice of the ruling faction. Bonaparte, when first consul, appointed a commission, consisting of Viellard, Target, Oudard, Treilhard, and Blondel, to frame a project of a criminal code. The fundamental laws were laid down in 1801, and were then discussed in the council of state. Bonaparte took a lively part in these first discussions, especially on the question of the institution of the jury, which he strongly opposed on the ground of the probable incapacity or party spirit of jurors: he looked upon the question in a political rather than a judicial light. Portalis, Simeon, Bigot de Préameneu, and Ségur sided with Bonaparte. Treilhard, Berlier, Defermon, Crétet, Bérenger, Merlin, and Louis Bonaparte defended the jury. There is an interesting account of this discussion in Thibaudeau (vol. vii., pp. 88, &c.). The question being put to the vote, the majority was favourable to the jury. The matter, however, was finally settled by suppressing the jury d'accusation, or grand jury, and retaining the jury de jugement. The jurors are taken from the electors, who are qualified to vote for a member of the legislature, graduates in law, medicine, and other sciences, notaries, &c. A list of persons so qualified is made out by the prefect of the department, from which the President of the Cour Royale, or of the Cour d'Assize, selects the number required to serve. The proceedings in criminal trials are partly written and partly oral. The accused is first brought before the procureur du roi (king's attorney), who examines him and simply reports the case to the juge d'instruction, without giving any opinion upon it. At the same time, if the accused is charged with a crime punishable with personal and degrading penalties, he orders his detention. For mere délits or misdemeanors, bail is allowed. The juge d'instruction summons and examines the witnesses, and then sends back the report to the procureur du roi, who makes his remarks on the case, which is then laid before the chambre de conseil, consisting of three judges of the tribunal de première instance. These judges investigate the case minutely, and decide if there is ground for further proceedings. In such case the report is laid before the chambre d'accusation, composed of five judges of the Cour Royale, who ultimately decide for commitment or acquittal. If committed for a crime punishable by peines afflictives or infamantes, the prisoner takes his trial before the next cour d'assise of the department. If for mere délit or misdemeanor, he is sent before the correctional tribunal. The courts of assize consist of a president and three judges, chosen from among the members of the Cour Royale and of the tribunal de première instance, and their sessions are held every three months in the chef lieu of each department. The jury decide by a majority on the fact of the charge; eight constitute a majority. The court then awards the sentence, having a discretion between a maximum and a minimum penalty. By a law passed since 1830 the court can no longer reconsider the verdict of the jury, as was the case before. The prisoner may challenge twelve jurors. One or two juges d'instruction are attached to each court of assize for criminal cases; they are generally taken from among the juges de première instance, and for a definite time only. The Code d'Instruction Criminelle consists of the following books: 1. Of the judiciary police and the various officers whose duty it is to inquire after offences, collect the evidence, and deliver the prisoners to the proper courts. These officers are very numerous, including the maires and their assistants, the commissaries of police, the rural guards and forest-keepers, the justices of the peace, the king's attorneys and their substitutes, the juges d'instruction, &c. It also treats of the manner of proceeding by the king's attorney, as already stated. Of the juge d'instruction and his functions, distinguishing between cases of flagrant crime and others. Book 2 treats of the various courts; tribunaux de simple police, which take cognizance of petty offences, and can inflict imprisonment of not more than five days, and a fine not exceeding fifteen francs; tribunaux en matière correctionnelle, which are composed of at least three judges of the tribunaux de première instance, and take cognizance of délits or misdemeanors, the penalties for which are defined in the Code Pénal; cours d'assise, already mentioned, from which there is an appeal for informality or want of jurisdiction to the Court of Cassation; lastly, the cours spéciales or exceptional courts, which Napoleon insisted upon having at his disposal, and which have been resorted to repeatedly since the Restoration, and still appear on the code. These special courts are assembled in cases of armed rebellion against the authorities, but they also take cognizance of the offence of coining and of crimes committed by vagabonds and convicts who have escaped; they are composed of a president taken from among the judges of the Cour Royale, four judges, and three military officers of the rank of captain or above. They try without jury, judge by majority and without appeal, and the sentence is executed within twenty-four hours. On the subject of the Code d'Instruction, Thibaudeau observes that it retained many of the ameliorations introduced by the National Assembly, especially the publicity of trial and the institution of the jury. Its chief faults are, the great number of officers, some of them merely administrative, who are charged with the pursuit of offenders, by which circumstance the citizens are often exposed to vexatious interference; the too great extent given to the jurisdiction of the correctional courts, by which, in many cases, the citizens are deprived of the guarantee afforded by the jury; the restrictions on the choice of jurors, which is too much in the power of prefects and other local authorities; the institution of the special courts; and, lastly, the frequent abuse of the power of the police, by which its agents could issue warrants of arrest.

'Prefects and commissary-generals of police often had individuals arrested, and left them in prison waiting for the decision of the minister of police, who answered at his leisure, or at times confirmed the order of arrest for an indefinite time. And as by Art. 75 of the Consular Constitution of the year 8, any suit against the agents of government was forbidden without an authorization from the council of state, there was in fact no redress against arbitrary acts.' (*Hist. de France sous Napoléon*, vol. vii. pp. 124—9).

This last abuse is now corrected, or at least greatly mitigated. Other provisions of the Code d'Instruction, as well as of the Penal Code, have been also altered for the better by the law of 28 April, 1832, entitled 'Modifications aux Codes d'Instruction Criminelle et Pénal,' which is found at the end of the later collections of the French codes.

The *Code Pénal*, or laws defining crimes and punishments, was completed in January, 1810. Its discussion occupied forty-one sittings of the council of state. Of these sittings Napoleon attended only one (21 January, 1809). Cambacères presided at all the rest. 'Napoleon was therefore a stranger to its discussions; he only expressed an opinion that the laws ought to be concise, and leave much latitude to the judges and the government in the application of the penalty, 'because,' said he, 'men had feelings of compassion unknown to the law.' He insisted upon the penalty of confiscation being retained in certain cases, because most nations had sanctioned it in cases of conspiracy, rebellion, and false coining. 'But the definition of crimes and offences, the nature of the penalties, and the mode of their application, were the work of criminal jurists, who were generally inclined to severity, and were well acquainted with the ideas of Napoleon, who was persuaded that criminal legislation ought to be very rigorous in order to maintain order and support the authority of the government.' (Thibaudeau, vol. viii. p. 3.) Hence the penalty of death was fixed in numerous cases, and those of perpetual imprisonment, hard work, or transportation for life, in a still greater number. The pillory is also one of the punishments.

If we look at book iii. ch. 1, which treats of the crimes and offences against the safety of the state (a term susceptible of indefinite and arbitrary application), we find that the penalties of death and confiscation are fixed very generally. Confiscation however has been solemnly abolished by a law passed under Louis XVIII. By the head, 'Des critiques, censures ou provocations contre l'autorité publique dans un discours pastoral,' any clergyman found guilty of having, in a pastoral charge, sermon, or other public address, spoken or printed, criticised or censured any act of the government authorities, is subject to banishment, transportation, and even death, according to the consequences which have resulted from his act. The following head, 'Résistance, désobéissance, et autres manquemens envers l'autorité publique,' is equally severe. The article 'Délits commis par la voie d'écrits, images ou gravures, distribués sans nom de l'auteur, &c.' concerns the press, which was under a strict censorship in Napoleon's time. Since the Restoration the censorship has been abolished, and several laws have been enacted to repress abuses of the press, especially in April and October, 1831. The last law on this subject was promulgated in September, 1835, and consists of five heads: 1. Crimes, délits et contraventions. 2. Du gérant (editor) des journaux ou écrits périodiques. 3. Des desseins, gravures, lithographies, et emblêmes. 4. Des théâtres, et pièces de théâtre. 5. De la poursuite et du jugement. It is printed at the end of a collection of codes, laws, &c., published in 1835, and styled 'Les dix-huit Codes du Royaume.' By the section of the Penal Code entitled 'Des Associations ou Réunions illicites,' which continues in force to this day, every association of more than twenty persons for the purpose of meeting on fixed days to discuss either political, religious, literary, or other subjects, is declared illegal, unless it first obtain the approbation of the government, which can prescribe conditions and fix regulations at its pleasure. The chiefs or directors of any such illegal association are punished by fine. If at the meetings of such assemblies there has been any provocation to crimes or délits, as defined in the other articles of the penal code, the chiefs or directors and administrators are liable to imprisonment from three months to two years, besides fine, although they themselves may not have been guilty of the offence. No individual can lend his house or apartments for the meeting even of an authorized association, unless he first obtain the permission of the municipal authorities. By a law which passed the Chambers in April, 1834, the above regulations have been made even more strict. Every member of an illegal association is liable to a fine of 1000 francs, and to imprisonment from two months to one year. Under the heads 'Vagabondage' and 'Mendicité,' vagrants are defined to be all those who have no fixed domicile, nor means of subsistence, and who do not follow habitually any trade or profession. On the legal evidence of being such, they are condemned to an imprisonment of from three to six months, after which they are 'at the disposal of government.' With regard to mendicants or beggars, any person found begging in a place where there is a workhouse or depôt for the poor is subject to from three to six months' imprisonment. But the next article is much more liable to objection on the score of justice and humanity; it runs thus:—In places and cantons where there is no depôt for the poor (which is the case in most rural districts of France), able-bodied beggars shall be imprisoned for a period of from one to three months; and if arrested out of the canton where they reside, they are imprisoned for a term of from six months to two years. By Article 402, bankrupts not fraudulent are liable to imprisonment from one month to two years. Brokers in the same situation are condemned to hard work for a time. The law of France makes a wide distinction between native and foreign insolvents. Foreigners not domiciled in France, having no commercial establishment or real property there, are liable to double the period of imprisonment that a Frenchman is, namely, two years for a debt less than 500 francs; four years for a higher sum under 1000 francs; six under 3000; eight for less than 5000; and ten years for 5000 and upwards. (Okey, *Concise Digest of the Law, Usage, and Custom affecting the Commercial and Civil Intercourse of the Subjects of Great Britain and France.*) By the head 'Violations des réglemens rélatifs aux manufactures, au commerce, et aux arts,' any coalition between masters to lower wages is punished by a fine of from 200 to 3000 francs, besides imprisonment not exceeding a month. Coalition among workmen, followed by an attempt to stop the works of a manufactory, is punished by imprisonment of from one to three months; the leaders or originators of the coalition or attempt are subject to imprisonment from two to five years. By Article 417, any one who, with the view of injuring French industry, has removed to a foreign country the workmen or clerks of a manufactory, may be imprisoned from six months to two years, besides paying a fine of from 50 to 300 francs. Article 418: Any director, clerk, agent, or workman, of a manufactory, who communicates to foreigners or to Frenchmen residing abroad any secret of the fabric in which he is employed, is punished by a fine of from 500 to 20,000 francs, besides imprisonment at the discretion of the court. Article 421: all wagers or bets upon the rise or fall of the public funds are punishable by imprisonment from one month to one year, besides a fine of from 500 to 10,000 francs. The offenders may after the expiration of their imprisonment be placed by sentence of the court under the surveillance of the haute police from two to five years. This sentence, 'placed under the surveillance of the high or government police,' which is added at the end of numerous penalties, means that the person so placed is to give security for his good conduct; in default of which he is 'at the disposal of government,' who may fix a particular place for his residence. All individuals who have undergone the punishment of hard work for a time, or that of banishment or transportation, or those who have suffered a penalty for political crimes, are placed, *de jure*, under the surveillance of the high police for the rest of their lives.

The above extracts are sufficient to show the spirit in which the French criminal code has been framed. It is, in fact, as harsh and illiberal in many of its enactments as that of any absolute government in Europe. In speaking therefore of Napoleon's legislation, it is necessary to discriminate between the civil and the criminal laws; and again between the laws themselves and the practice and rules of proceeding in the courts. The adoption of the French criminal code met with great opposition in Italy. At Milan the legislative body attempted to modify and adapt it to the habits and wants of the Italians. Two commissions were appointed by the minister of justice, one for the code of instruction, and the other for the code pénal. Their reports were sent to Paris, but were rejected by Napoleon, and an answer came with peremptory orders to translate literally, and enforce the two French codes without any alteration. At Naples similar objections were also made, but with no better effect. (Colletta, *Storia del Reame di Napoli*, book vi.)

For comments and strictures by French jurists on the criminal laws of France, see Bérenger *de la Justice Criminelle en France*, 1818; Dupin, *Observations sur plusieurs points importans de notre Législation Criminelle;* and Bavoux, *Leçons préliminaires sur le Code Pénal*, 1821.

There are in France more than 3000 judges, including those of the commercial courts, besides 2840 juges de paix. The judges of the Tribunaux de Premiere Instance have salaries varying from 2000 to 6000 francs; those of the Cours Royales, from 3000 to 8000. The presidents and vice-presidents receive more in proportion. The juges de paix receive about 800 francs, besides certain fees. The various courts, magistrates, greffiers, &c., cost the state about fifteen millions of francs annually. (Goldsmith, *Statistics of France*, 1832.)

For a general view of the judiciary system of France, see Meyer, *Esprit des Institutions Judiciaires*, last vol.; and Rey, *des Institutions Judiciaires de l'Angleterre comparées avec celles de France et de quelques autres Etats*, 1826

CODICIL, in English law. [Will.]

CODICILLUS, the diminutive of Codex, signifies properly something written on a little wooden tablet. Cicero (*ad Fam.* iv. 12, vi. 18; *ad Attic.* xii. 8; *ad Quint. Fratr.* ii. 10) often uses Codicilli for epistolæ, or letters. Codicilli, in fact, were letters addressed by a testator to the heir or heirs named in his will, as to certain things which the testator wished to be done by his heir or heirs after his decease. (Heinecc. *Antiq.* ii., tit. xxiii and xxv., section xi.)

The difficulty which existed, out of Rome, of procuring the legal number of Roman citizens as witnesses to a solemn will, led to the use of Codicils. It appears from Justinian's 'Institutes' (*de Codic.* ii., 25) that codicils came into use in the time of the Emperor Augustus. Lucius Lentulus, who died in Africa, had addressed a codicil (that is, a letter) to Augustus, his testamentary heir, who complied with the wish of Lentulus, though he was under no obligation to do so. From that time codicils became legal instruments.

The Codicillus has been defined to be a supplement or addition to a testament, which is to be considered as annexed to the will itself, for the purpose of adding, explaining, or altering something in the previous disposition. But such a definition does not give an exact notion of the term, and besides this, it applies only to the cases where the person making the codicil dies testate; consequently it does not take in those cases where no will exists. More correctly, codicil is defined to be a less solemn will, in which, as well as in a solemn will or testament, every disposition that can be effected by a last will may be made, except the appointment of direct heirs, and exheredation, *i.e.*, the disinheriting of sons, daughters, &c. Codicils were commonly used for the purpose of naming bequests or legacies to be paid by the heirs already appointed by a testament, and for explaining and clearing up obscurities and want of precision in a testament.

There are two species of Roman Codicils: *ab intestato*, when a man who made a codicil died intestate; and *codicilli ad testamentum facti*, when he died testate. In the former case the dispositions in the codicil had reference to the heres ab intestato, or the person to whom the law gave the intestate's property. Codicils of the second species were either confirmed by the testament (codicilli confirmati) or not (non confirmati). Before Justinian's time there were several differences between these two sorts of codicils, particularly as to legata and fidei commissa; but the different species of bequests being put on the same footing in the reign of Justinian, the distinctions ceased. In the time of Pliny the Younger, a codicil made before a subsequent will ought to be confirmed by the will (lib. ii. ep. 16); but this was afterwards dispensed with (*Instit.* ii. 26). Sometimes future codicils were confirmed by a prospective will.

Codicils might be written, in which case they were either public or private; or they might be verbal directions given to the heir. In their origin codicils had no particular forms; but the Emperor Constantine required witnesses to codicilli ab intestato, and to codicilli non confirmati; and Justinian required witnesses for all private codicilli.

A testament wanting the legal forms required for such a solemn instrument might be maintained as a codicil if the legal forms for a codicil were observed, and the will contained the codicil-clause (clausula codicillaris). (See Brissonius *De Formul.* lib. viii.; Gaius, lib. ii., Dig. 29, Tit. 7; *De Jure Codicillorum.*)

CODIFICATION. [Law and Legislation.]

CODRUS (Κόδρος), son of Melanthus, and the last king of Athens, as to whom the following tradition is preserved. When some of the Dorian states had united their forces for the invasion of Attica, they consulted the Delphic oracle concerning the issue of the expedition. The response implied that they would be victorious if the life of the Athenian king was spared. The Athenians being informed of this answer of the oracle by Cleomantis, an inhabitant of Delphi, Codrus heroically determined to devote himself for his country. Accordingly he went out at the gate disguised in a peasant's dress, and falling in with two Dorians, killed one with his hook, and was himself killed by the other. The Athenians demanded and got back the body of their king; and the Dorians, despairing of success, withdrew their forces. The exact spot where Codrus was said to have fallen was shown in the time of Pausanias (i., 19), near the altar of the Muses, on the Ilissus. Codrus had several sons: the two eldest were Medon and Nileus. Cleomantis and his descendants were rewarded with the freedom of the city, and a perpetual right to sit at the public table, which was kept in the Prytaneum at Athens. (*Lycurgus against Leocrates*, sections 194 and 196; Pausanias, vii., 225.)

CO-EFFICIENT (in Algebra). When two or more numbers are multiplied together, each of them is called a factor of the product, and a co-efficient (or co-factor, as it were) of the other factors. Thus the factors of the product $a \times b \times c$ are a, b, and c; and a is the coefficient of $b \times c$, b of $a \times c$, and c of $a \times b$. But the word is most frequently used for that which should be distinguished as a numerical coefficient; thus in $2x + 3y$, 2 and 3 are respectively the coefficients of x and y. This word is as old at least as the writings of Vieta, in which it has its present sense.

When there is a multiplier depending upon the result of experiment connected with any particular property of matter, the number is frequently called the coefficient of that property. Thus by the coefficient of friction for any substance, is meant the fraction of the pressure which is equivalent to the friction of that substance.

COEHORN, MENNON, BARON DE, a celebrated Dutch engineer, who was born in 1632. He commenced his military career at an early age, and spent the leisure which the intervals of active duty afforded in improving the art of fortifying places, with the view of diminishing the inequality which, by the inventions of his contemporary Vauban, began then to be felt in the means of attack and defence. The services which Coehorn rendered to his country, both as an engineer and a commander, at a time when the defence of its military posts was an object of the first importance, procured for him the most honourable appointments which a soldier can attain. He arrived at the rank of general of artillery, and was made director-general of fortifications and governor of Flanders.

At the siege of Namur in 1692, Coehorn gallantly defended the fort which he had before constructed for the purpose of strengthening the citadel of that place, but being dangerously wounded he was at length compelled to surrender. It is honourable to the character of Vauban, who conducted the operations of the attack, that on this occasion he rendered full justice to the talents and valour of his rival.

Coehorn was engaged at the attack of Trarbach, Limburg, Liege, and at that of the citadel of Namur, which three years before he had defended. In the year 1703 he was employed at the siege of Bonn, where, in three days, his heavy and well-directed cannonade caused the surrender of the place. Soon afterwards he forced the French lines at Hanuye, and was appointed with his army to keep in check the Marquis de Bedmar on the right bank of the Scheldt. This was his last service: in the following year (1704) he died at the Hague, at the age of seventy-two.

In 1685 Coehorn published what are called his Three Systems of Fortification; they are adapted to ground elevated but from three to five feet above the surface of water, and consequently they may be considered as applicable only to the towns of Holland. He was appointed to repair or reconstruct the fortifications of Nimeguen, Breda, Mannheim (since destroyed), and Bergen-op-Zoom. The siege of the last place in 1747, by its duration and the losses which the besiegers sustained in its progress, attests the merit of the system on which the works were constructed.

COEHORN, a small mortar for throwing grenades, invented by the engineer of that name.

CŒLINO. [Isopoda.]

CŒLIUS, or rather **CÆLIUS ANTIPATER** (**LUCIUS**), wrote a history of the second Punic war, in a work bearing the name of 'Annals,' and extending to at least seven books. Some indeed are of opinion that the history embraced a much wider period, beginning with the first Punic war, and including the times of the Gracci. It was dedicated to L. Ælius, the same person to whom the poet Lucilius dedicated his 'Satires.' The precise period of his birth or death cannot be fixed, but he is called by Cicero (*De Leg.* i., 2) the contemporary of C. Fannius Strabo, himself an historian, and we know that Fannius was with Scipio at Carthage, in 146 B.C., and Consul in 122. That Cœlius lived about this period is confirmed incidentally by an anecdote reported by Cicero (*De Divinat.* i., 26). When Caius Graccus was a candidate for the quæstorship, his brother Tiberius appeared to him in a dream, and warned him that he would perish by the same violent fate which had befallen himself. And Cælius tells us, says Cicero, that he both heard of this dream and spoke of it to others before Caius Graccus was elected tribune, and consequently several years before it was fulfilled. Now the death of Tiberius Graccus occurred in 133. His brother Caius was quæstor in 126, tribune for the first time in 123, and murdered in 121. Lastly, the orator, L. Crassus, born 140, was one among many pupils of Cælius. We shall therefore not be very wrong if we suppose Cælius to have been born about the middle of the second century B.C.

The historical writings of Cælius were highly valued by his countrymen in the time of Cicero, who assigns to him the credit of having surpassed his predecessors in historic composition by the dignity and eloquence of his style. Though he wanted that knowledge of the jurisprudence of his country which is essential to an accurate historian, yet he was a man of an inquisitive temper, and seems generally to have the advantage in point of credibility where he differs from the historians of the same period. Marcus Brutus so highly prized his writings, that he made an epitome or abridgment of them, as he had before done of the histories composed by Polybius and Fannius. But the more complete work of Livy threw all the historical works of his predecessors into oblivion. Cælius was afterwards seldom read, except by antiquarians and those who sought in his writings examples of quaint words and obsolete phraseology; it is to the grammarians therefore that we are chiefly indebted for the fragments of his works that still exist. These fragments, together with those of other Roman historians, may be found in an appendix to Cort's and Havercamp's editions of Sallust. They have also been edited by Krause (*Vitæ et Fragmenta Veterum Historicorum Romanorum*, Berol., 1833). One of the most interesting among them is that in which he bears testimony to having seen a merchant who had sailed from Spain as far as Ethiopia, by which he probably meant the Coast of Guinea. It is Cælius too who gives the most direct evidence in favour of Hannibal's route across the Alps having been by the Little St. Bernard.

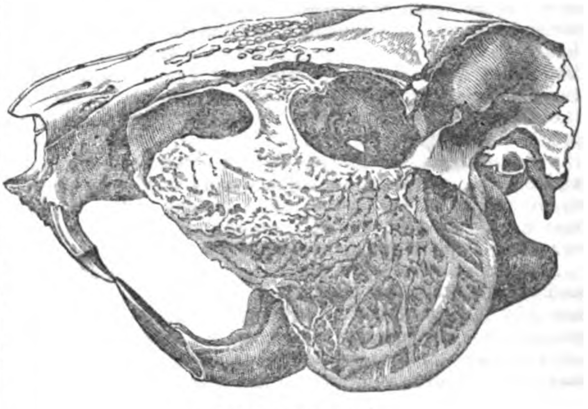
The Greek name Antipater, attached as a cognomen to that of Cælius, has with some reason led to the belief that he or his father was of Greek origin, and becoming a Roman prisoner and slave by the chance of war, was afterwards emancipated, and then took, as was the custom, the name of his Roman master. Such an origin is confirmed by the fact, that the name of one so distinguished by his talents, and especially his eloquence, is nowhere mentioned in connection with any public appointment. Two copious dissertations on L. Cælius, by B. A. Nauta and W. G. Van Prinsterer, will be found in the Annals of the Academy of Leyden for 1821. (See *Krause* as above.)

CŒLIUS, MONS. [ROME.]

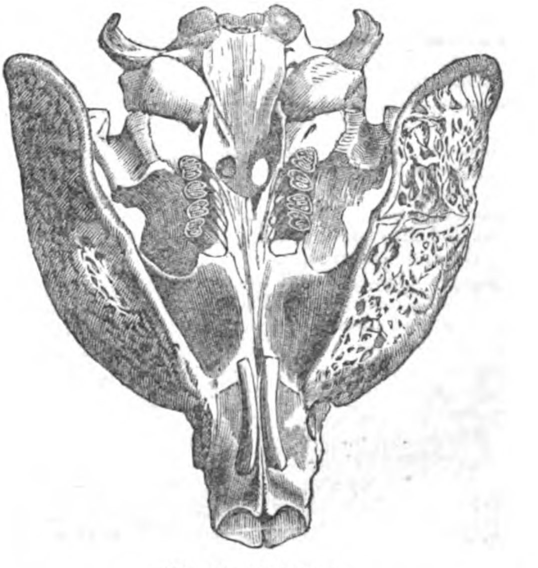
CŒLO'GENUS (F. Cuvier), *Cœlogenys* (Illiger), a genus of Rodent animals, belonging to the division without clavicles. Its place among the older naturalists was either among the Rats (*Mus*) or among the Hares. Linnæus, in his last edition (the 12th), arranges it under his extensive genus *Mus*, with the denomination of *Mus Paca*, and quotes, among others, Ray, who termed it *Mus Brasiliensis*. Klein separated the Cavy, Agouti, and the animal before us from the mass, under the generic appellation of *Cavia* Gmelin, in his edition of Linnæus (the 13th), followed Klein, and added to the Cavies and Agoutis the Capybara, which Pallas, in his 'Spicilegia,' had termed *Cavia Capybara**, and Linnæus had placed among the Hogs (*Sus*). M. F. Cuvier separated the Paca from the Capybara, the Cavies, and the Agoutis, to which forms it shows a strong approximation, but from which it also presents considerable differences in many points, and especially in the complex structure of the molar teeth.

Dentition, &c.—Two strong incisor teeth in each jaw, the upper ones flattened in front and truncated obliquely, chisel-like; the lower slightly compressed laterally, and rounded on the anterior face. But these incisors, though of some strength, are small when compared to those of the porcupines and of the beaver. Like all the true Rodents, *Cœlogenus* has no canines, and a void space or bar separates the incisors from the molars, which amount to eight in each jaw, and are not unlike those of the Agouti, that is to say they are composed of complicated riband-like plates of enamel set in the interior bony cement, which vary and become more or less visible according to the greater or less attrition which the crowns have undergone. But, in *Cœlogenus*, besides the difference in the complications, the molars augment in size from the first to the last, which is one-third larger than the tooth that precedes it. (F. Cuvier.) There is also a striking peculiarity in the great development and projection of the zygomatic arches, which are enormously large, giving great breadth to the face, and descending unusually low. These were remarked by Daubenton; and Buffon observed that, on each side and towards the lower part of the upper jaw, there existed a sort of longitudinal fold, destitute of hair in the middle, so that, at first sight, it might be mistaken for the mouth of the animal. This fold, which Buffon does not seem to have investigated, is the opening of a shut sac of some extent, extending upwards behind the arch formed by the cheek and temporal bones, whose inner surface, as far as the sac extends within them, is lined by a continuation of the integument of the face, and, in addition to it, the animal is furnished with true cheek-pouches in their usual situation. These last are capable of being greatly dilated, and when filled, they are said to occupy the whole space beneath the zygomatic arches.

Dental formula· incisors, $\frac{2}{2}$; molars, $\frac{4}{4} = 20$



[Skull of Cœlogenus.]

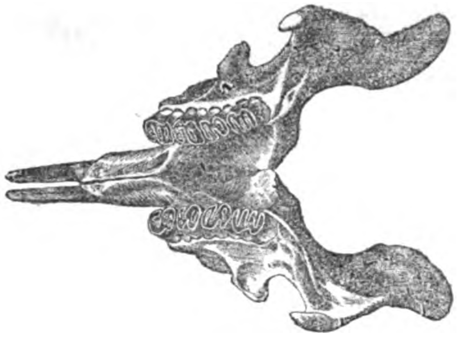


[Upper jaw of the same.]

M. F. Cuvier observes that the Pacas are, among the Omnivorous Rodents, what the Capybaras are among the Herbivorous section. The first possess molars with roots distinct from their crowns, to the number of four on each side of either jaw. Those of the upper jaw are nearly of a size; but, in the lower, they diminish gradually from the last to

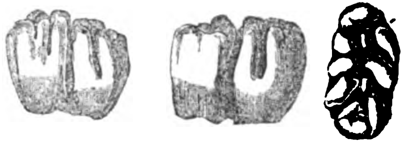
---

* N.B. There was a reference to Capybara from Cabiäi. The reader will find that animal, whose history was omitted under the title referred to, described in the article HYDROCHŒRUS.



[Under jaw of the same.]

the first. All the molars, before they have been subjected to the process of mastication, present, on the upper surface of the crown, four tubercles, which more or less completely divide the tooth broadwise, and are separated by three transverse furrows, more or less large or deep. When the crown of the tooth is exposed to mastication, the top of the tubercles begins to wear away, and the enamel, instead of forming a sort of hood or cap, presents a series of ribandlike foldings, the outlines of which are conformable to the tubercles and furrows. In proportion to the continuance of the abrasion, the tubercles are successively effaced; and, finally, nothing is to be seen but the enamel, which hoops the tooth externally, and that which penetrates the interior and is there complicated, the plaits going very deep, so that the ribands of enamel, whose edges are exposed on the triturating surface, change their appearance with the age of the animal, and terminate by disappearing in great measure.



Germ of the first molar, enlarged. View of the outside, inside, and crown.—(F. Cuvier.)

Approximations.—The Pacas approach the Capybaras and the Agoutis most nearly, and are closely allied to the latter by their general form and the similarity of their organization. The dental and generative systems in both are very nearly alike: neither have clavicles, nor indeed has the Capybara; and though the Agouti has only three toes on the hind feet, the two additional hind toes of the Paca are hardly more than rudiments. The great differences consist in the zygomatic development, the folding back of the skin under the zygomatic arch—and the consequent bluff appearance of the head—the cheek-pouches, and the fur.

Species.—M. F. Cuvier records two species, viz., *Cœlogenus subniger* and *Cœlogenus fulvus;* but Baron Cuvier, in the last edition of the 'Règne Animal,' treats them as varieties of the same species; and he adds in a note, that Dr. Harlan (' Fauna Americ.' p. 126) has founded, on a head preserved in the Philadelphia Museum, a new genus under the name of *Osteopera*, but that it appears to him (Cuvier) that the description is only that of the Paca; and he concludes by stating that M. Desmarest had already made the same observation.

Example, *Cœlogenus subniger*.—Its general appearance reminds the observer of the Pachydermatous animals, for it is thick-set and stubby. The legs are thick, the neck short, the head heavy, the body rounded, the gait clumsy, but the motions of the animal are prompt and sudden. All the feet have five toes, which, anteriorly, have the ordinary proportions, but, posteriorly, the analogues of the little toe and great toe are extremely short in proportion to the rest, and almost rudimentary, like the upper or lateral toes in the hog. The claws are conical, thick, and strong, and proper for digging. The tail is reduced to a naked, immovable tubercle, a few lines in length. The principal male organ is directed backwards, and there is no external appearance of the testicles. The external ear is moderate in size, rounded, and simple. There is nothing particular about the eye, the pupil of which is round. The nostrils, which are large and almost united, open transversely at the muzzle. The tongue is very soft, short, and thick. The upper lip is divided, the interior of the mouth is furnished with cheek-pouches, and, externally, the large area formed by the development of the zygomatic arcn is lined on its inner surface with a continuation of the skin of the cheeks, which is reflected from the face, so as to form a hollow pouch, of which there is no other example among mammiferous animals, and the use of which it is difficult to divine, if the great development of the zygomatic arch be not destined to preserve the true cheek-pouches (abajoues) from external shocks. Strong whiskers spring from the sides of the muzzle, and from behind the eye. The fur is composed of silky hairs, very short, very thin, and very stiff, of a blackish-brown on all the upper parts of the body, excepting four rows of parallel spots, which begin at the shoulders and terminate at the buttocks: the spots of each row are so approximated, that when viewed in a particular direction they seem to form an uninterrupted line, and the row nearest the belly is almost confounded with the colour of that part, which is white, as well as the under parts of the lower jaws, the internal surface of the limbs and the claws. Length of the body, from the occiput to the insertion of the tail, sixteen inches: length of the head, from the occiput to the end of the muzzle, five inches. Height, to the shoulders twelve inches—to the top of the buttocks (train de derrière) fourteen inches, French. (F. Cuvier.)

Geographical Distribution.—This animal is better known as the Paca of zoologists generally, and, after the Capybara and Coypu, is one of the largest of the South American Rodents. It is the Spotted Cavy of Pennant and Bewick, the *Pag* of the Brazilians, *Paig* of the inhabitants of Paraguay, *Ourana* of some of the tribes of Guiana and *Pakiri* of others, the *Pak* of the colonists of Cayenne, and the *Water Hare* of those of Surinam. In all these countries it is common, with the exception of Paraguay, where, according to D'Azara, it is very rare. They formerly existed in the islands of the West Indies.

Habits.—In a state of nature the habitation of the Paca is in low humid forests, and in the neighbourhood of water. The animal digs a burrow like the rabbit, but much less deep; indeed it is so near the surface, that the foot of the pedestrian often breaks through, and, sinking into the tunnel, drives out the tenant. There are generally three issues to a burrow, and the aperture of these the animal covers with dry leaves and branches. To take it alive, the hunter stops two of these apertures, and digs into the third; but when the penetralia are reached, the hapless besieged makes a most determined resistance, fighting the enemy with ferocity, and trying to bite. When undisturbed, it often sits up and washes its head and whiskers with its two fore-paws, which it licks and moistens with its saliva at each ablution, like a cat; and with these fore paws, as well as with the hind ones, it often scratches itself and dresses its fur. Though heavy and corpulent, it can run with a good deal of activity, and often takes lively jumps. It swims and dives with great adroitness, and its cry resembles the grunting of a young pig. Its food consists of fruits and tender plants, which it seeks in the night, hardly ever quitting its burrow in the day, the strong light of which, as is the case with other nocturnal animals, is oppressive to its eye: the planter often rues the visits made by these midnight foragers to his sugar-canes. The female is said to bring forth at the rainy season, and to produce but a single young one, which stays a long time with the mother. The Pacas are very cleanly creatures, never dropping their excrements near their dwellings, but going to a considerable distance for that purpose.

In captivity, according to M. F. Cuvier, no animal can exhibit less intelligence. When offended, it throws itself violently at the object which has displeased it, and then makes a grumbling, which breaks out into a kind of barking; and when it is not eating it is sleeping. But it requires a soft and well-made bed; and, to obtain this, it collects with its mouth hay, herbage, straw, anything indeed that suits its purpose, of which it makes a little heap, and then lies down in the centre of it. This bed it never defiles, but goes to the extremity of its cage the farthest removed from it, and constantly resorts to the same spot for the same purpose. If, says M. F. Cuvier, it is but little favoured on the side of intelligence, it appears on the other hand to be recompensed by a large share of instinct, to judge, at least, by appearances. Mr. Bennett, from his observation of one which lived for some months in the garden of the Zoological Society in the Regent's Park, says that it is quiet and contented in captivity. Buffon, who kept one for some time in his house, found it familiar and mild. He gives a detailed account of its manners and mode of life in the 10th vol. of his works, to which we refer the reader.

The Paca has been long known. Marcgrave, Piso, John de Laet, Maffé, Jean de Lery, D'Azara, and Barère all mention it. Jean de Laet describes it in two different places (pp. 551, 618) under the names of *Pag*, or *Pague*, and *Pac*. Marcgrave gave a very bad figure of it, Piso followed, and Jonston copied Piso. Buffon gave a much better representation, copied by Schreber. Bewick's is not without character; and the figures given by M. F. Cuvier (*Histoire Naturelle des Mammifères*, tome 3) and by Mr. Bennett (*Gardens and Menagerie of the Zool. Soc.*, vol. i.) are very good.

Utility to Man.—The flesh is stated to be excellent and of good flavour; but as it is very fat and rich, it soon cloys: it is prepared for cookery by being scalded like a sucking pig. Piso gives the following character of its merits for the table:—'Carne est tenera, pingui lardo non indigens, si assetur, sed inter epulas magnatum, sicut lepores et capreæ in Europâ, habetur.' Its skin is of no value to the furrier; but its thickness might make it available in the useful arts. M. F. Cuvier thinks that it would be possible to introduce this animal into our European rural establishments, and that it would form a very good acquisition in the department of domestic economy

COETHEN, or KOETHEN. The duchy of Anhalt Cöthen (or Köthen), in the territory of Anhalt, is bounded by the dominions of Prussia, Dessau, and Bernburg. It consists of four detached districts: Cöthen Proper, the bailiwick of Warmsdorf, Lindau, and Dornburg. Cöthen Proper is skirted on the north by the Fuhne, and on the east by the Saale. The whole comprise 310 square miles, and contain 4 towns, 1 market-town, 94 villages, and about 6000 houses. The duchy altogether is a level, with the exception of occasional and in considerable eminences. The whole surface is covered with rich corn-fields and meadows, whose fertility is proverbial. Nearly all the roads are planted with fruit-trees. The climate is mild. Besides the Mulde, Eine, and Selke, the duchy is watered by the Elbe, Saale, Wipper, Liethe, Bude, and other streams. A considerable fishery is carried on in the Saale, Bude, and Elbe. The chief products are rye, barley, wheat, buckwheat, vegetables and fruits, hops, potatoes, rapeseed, oil, flax, &c. On the left bank of the Elbe are quarries of lime and gypsum. The inhabitants are chiefly engaged in agriculture and the rearing of cattle, especially oxen and sheep; they are also employed in the manufacture of oil, yarn, linen, wool, and leather, but in very inconsiderable quantities. The population in 1831 was 36,000, of whom two-thirds are employed in agriculture. Of the forty-eight parishes, twenty-eight belong to the Reformed Lutheran, nineteen to the Lutheran, and one to the Roman Catholic church. The principal places of trade, besides Coethen, are Nienburg, at the confluence of the Saale and Bode (about 1900 inhabitants), St. Güsten on the Wipper (about 1640), and Rosslau on the Elbe (about 1400). The income of the duchy is about 320,000 guilders, or 30,700*l.* sterling, exclusive of the duke's large patrimonial revenues. The public debt is about 115,000*l.* The duke has also extensive private property in the Russian province of Taurica, called Ascania Nova, amounting to about 134,000 acres, chiefly pasture ground, on which above 22,000 Merino sheep are fed. It was purchased by him in 1828. The permanent military force of Coethen consists of 329 men. The duchy is under the protection of Prussia.

COETHEN, the capital, lies in a fertile but low situation, at a short distance from the river Zittau, nearly in the centre of the duchy, between the Elbe, Fuhne, Saale, and Mulde, in 51° 45′ N. lat., and 12° 3′ E. long. It was founded by the Sclavonians, and is conjectured to be the Kietni, Kieta, or Gietana, a chief town of the Gietanes: it was devastated in 927 by Henry I. The streets are broad and well paved, and the town upon the whole presents a neat and pleasing appearance. It is the duke's residence, is about half a league in circumference, and surrounded with high walls. It is divided into the old and new town, and the chief buildings are the palace and castle, town-hall, and one Reformed, one Lutheran, and one Roman Catholic church. It also possesses various charitable institutions, particularly an excellent school for the indigent, in an old Carmelite monastery; a grammar and a normal school, a public library and museum of natural history, picture gallery, Bible society, &c. The number of houses is 784, and of inhabitants about 6050; two-thirds of them are Lutherans, and the remainder of the Reformed church.

COFFE'A, a Cinchonaceous genus, consisting of many species of tropical berry-bearing shrubs, one of which, Coffea Arabica, is celebrated for the agreeable stimulating effect of an infusion of its roasted albumen. This substance, the coffee of commerce, is to that plant what the flour is to corn, the white meat to a cocoa-nut, and the aromatic ruminated substance to a nutmeg. It is a secretion formed in the interior of the seed, and enveloping the embryo plant, for whose support it is destined when it first begins to germinate; it constitutes the principal part of the seed, the embryo itself being a minute body lying in a cavity at one end of the albumen. Unskilful observers are often unable to find the embryo; but it may readily be seen by the following simple means:—Take a new sample of small fine unroasted Mocha coffee, and throw it into boiling water; the embryo will, after a little while, be expelled with force from the albumen in a majority of cases.

The genus Coffea is known among Cinchonaceous plants by having a tubular corolla, with four or five spreading divisions; stamens arising from the naked throat of the corolla, and either extending beyond it or inclosed within it; and a succulent berry containing two cells lined with a cartilaginous membrane, of the texture of parchment, in each of which cells there is a single seed, convex at the back and deeply furrowed in front, in consequence of the albumen being rolled inwards.

Coffea Arabica is an ever-green shrub, with oval shining wavy sharp-pointed leaves, white fragrant five-cleft clustered corollas with projecting anthers, and oblong pulpy berries, which are at first of a bright red, but afterwards become purple. It is stated by Niebuhr to have been brought from Abyssinia to Yemen by the Arabs from a country similar to their own plains and mountains. By that people it has for ages been cultivated in the hilly range of Jabal, in a healthy temperate climate, watered by frequent rains, and abounding in wells and water-tanks. Here the plants are grown in grounds that are continually irrigated, and in soil from 1 to 1½ foot deep. Among the plantations are interspersed various kinds of trees, whose shade has a beneficial effect upon the coffee bushes. When in flower, they diffuse a most delicious harmless fragrance, in the midst of which the natives fix their habitations. The fruit begins to ripen in February; and when the seeds are prepared, they are conveyed to the city of *Beit el fakih*, whence part goes to Mocha, and another portion to Hodeida and Loheia, whence it finds its way to Djedda and Suez for the Turkish and European markets.

The climate of the Jabal hills is described by Niebuhr as rainy every day from the beginning of June to the end of September, and the quantity of wet is stated to be so great as not only to fill the Wadies, but to soak the earth both of the lowlands and the hills so much as to keep water throughout the year in the rivers Zebid and Suradj. This enables the cultivator to provide abundant irrigation for his coffee plantations during the dry season, while that object is further facilitated by the terrace plan of cultivation. Scarcely anything further is known of the climate in which the fine Arabian coffee is procured, unless we add the meagre statements of Forskähl as to the temperature of two or three coffee districts

Beit el fakih	. Mar. 16,	7 A.M.,	76° Fahr.;	1 P.M.,	95°;	10 P.M.,	81°

and that the summit of the mountain-ridge of Jabal is so high as to be commonly enveloped in clouds, while the valleys below are lying beneath a pure and cloudless sky.

We have been thus particular about the circumstances under which coffee is grown in its greatest state of excellence, because of its importance as an article of consumption, and because of the inferior quality of all the samples that dother countries have as yet been able to produce.

Richness of soil in the West Indies has been thought to be the cause of the inferior quality of coffee grown in that part of the world, and to the supposed dryness of Yemen has been ascribed the excellence of Mocha coffee. But it has been shown that the Arabs counteract the effect of any dryness in the air by abundant irrigation; and that moreover it is not in the Tehama or dry parts of the country that it is cultivated, but on hill-sides, where the temperature is much lower, and where it rains daily for four months in the year. What is most essential to attend to in all speculations concerning the cultivation of the plant with a hope of equalling its quality in Arabia, is to select a climate where the heat of tropical plains is counteracted by elevation in the air; where during the dry season water can always be commanded in abundance, and where most especially the air is pure and cloudless, so that there may be no loss of light by the intervention of a cloudy sky. Light would seem, from Forskähl's account—short as it is—to be poured upon the coffee country in an uninterrupted flood; and the excessive stimulus thus communicated to all the functions of vegetation, which under other circumstances would probably prove deleterious, is, by an excellent system of irrigation, and the natural dampness of the soil, not only counteracted, but made the cause of the perfect elaboration of those delicate and subtle principles upon which the aroma and active qualities of coffee and all other plants are so entirely dependent. In this and similar considerations it is always to be borne in mind that it is not temperature, nor atmospheric pressure, nor humidity, whether of air or soil, nor light, that by themselves constitute the conditions under which alone plants arrive at their most perfect state, but the peculiar combination of these influences; a combination which varies from country to country, and may in some cases be actually confined within such very narrow natural limits as not to be exactly paralleled elsewhere, although in the majority of instances it may be readily matched in similar latitudes.

[Coffea Arabica.]

a. Corolla opened, showing the stamens; b, pistil; c, berry; d, e, sections of the seed; f, embryo.

The seed of *Coffea Arabica* consists of much horny albumen, and a peculiar principle or alkaloid, termed *cafeine*, [CAFEINE], which contains more nitrogen than any other known vegetable substance. The seed is used in a raw state in medicine; but when roasted, both as a medicine and still more extensively as an article of diet. The coffee-plant begins to produce fruit when two or two and a half years old; but the quality of the seeds from young stems is not so good as that from stems four or five years old. The size and colour of the bean (as the inner part of the seed is called) vary considerably, those from the West Indies being larger than those from the East. Much more depends upon the manner of roasting and making the coffee, than upon the quality of the bean. The superiority of French coffee, in the preparation of which little or no Mocha coffee is used, proves this position. Beans of a good quality are hard and heavy, sink quickly in water, are of a light yellowish green colour, not discoloured or black, and possess the odour of coffee, which though faint is peculiar, and are free from any damp smell. Beans recently collected, or only two or three months from the tree, are not so good as those about a year old; when older than this they become deteriorated. From the analysis of Seguin and Schrader, coffee consists of coffee-bitter (impure caffein), solid fat, resin, a little aromatic principle, gum, albumen (this albumen, according to Seguin, unites with the yellow coffee-bitter, and forms a green), and lignin. The taste of raw coffee is somewhat sweetish; but the application of heat in the process of roasting produces important changes. The bean increases to nearly twice the original size, while it loses about a third of its weight: a powerful and agreeable odour is evolved, and a large quantity of empyreumatic oil, which appears in small drops on the surface, is formed along with a bitter principle, probably by an alteration in the caffein, and of the saccharine matter. The roasting should take place in a close revolving iron cylinder, over a clear but moderate fire, and should not be carried too far: when the beans have acquired a light chestnut colour, the roasting should be discontinued. The beans are then to be cooled quickly by being tossed up into the air, and the grinding, or rather rough pounding, should be performed in a covered mortar or mill. The drink should be prepared from it as soon as possible, by infusion, which is preferable, unless some apparatus be employed by which a kind of decoction is made in a close vessel, such as Parker's steam-fountain coffee-pot. About half an ounce of coffee powder should be used for every eight ounces (half a pint) of water. In Britain the roasting is generally carried too far; and the subsequent parts of the process, instead of being performed immediately, are often postponed for days or even weeks, by which the aroma is dissipated: when made, the liquid is generally deficient in strength and clearness. The employment of white of egg or fish-skin to clarify is decidedly objectionable: clearness is thus purchased, but at the expense of the strength.

The addition of milk (which should always be hot) and of sugar heighten the nourishing qualities of this beverage, and in the morning render it a more substantial article for breakfast. When taken after dinner to promote digestion it should be without milk, and, where the palate can be reconciled to it, without sugar.

The action of coffee on the human system is due chiefly to the empyreumatic oil, and consequently is greatest when roasted; but its extractive and also highly nitrogenous principle must exert considerable influence upon the organs of digestion.

Coffee acts powerfully and peculiarly on the ganglionic system of nerves and their ramifications, and all the organs which are supplied by them. It elevates the vitality of these nerves, and quickens all their actions. The brain is likewise markedly acted upon by it; and hence the increased sensibility and greater energy of that organ during the use of coffee, and the removal of all sense of fatigue or disposition to sleep. Upon this depends, in addition to its local influence upon the organs of digestion, the utility of coffee in counteracting the effects of narcotic poisons, such as opium or belladonna, and the favour it has found among literary persons from enabling them to carry on their studies through the midnight hour without feeling oppressed by sleepiness. It greatly promotes digestion if taken after dinner, and also checks the disturbance of the nervous system arising from the too free use of wine. It excites the vascular system, and renders more powerful the contractions of all the muscles, both voluntary and involuntary. It fits the system therefore to resist the influences of cold and damp, and is proper for night travellers and the inhabitants of humid climates, such as Holland. In warm climates it removes the languor which oppresses those who are exposed to the excessive heat, and helps the stomach to perform its office.

It is not without its counterbalancing disadvantages. For plethoric persons, and those who have a tendency to abdominal congestions, it is unsuited; and for persons subject to piles it is in general improper, as well as for females under certain states of their system. It is likewise hurtful to persons having a very excitable vascular system, being upon the whole more suitable for slender persons or those advanced in life, than for the young or very robust.

Coffee, like all stimulants, when used to an injurious extent, gives rise to disturbances of the nervous system, particularly painful twitchings of the upper eye-lid, to congestion or hæmorrhages, loss of digesting power, and obstruction of the liver and *vena porta*. Unlike the nervous symptoms caused by tea, the greatest number of these complaints subside or disappear on discontinuing the use of the strong beverage.

Coffee is much more extensively used as an article of diet than of medicine. Raw coffee, either in the form of powder or of infusion, has been found very serviceable in the cure of intermittent fevers. (*Edinburgh Medical and Surgical Journal*, No. lxii.) A strong infusion of coffee without sugar or milk often removes megrim or hemicrania; and also in some cases of asthma, either alone or with tincture of opium, it has kept off the paroxysm. Strong coffee is the best and safest means which can be employed by unprofessional persons to obviate the effects of all vegetable poisons which act upon the brain, and induce a fatal sleepiness and torpor. It is much more proper than vinegar, which should never be given till all the poisonous substance has been removed from the stomach.

In some affections of the kidney and bladder, such as laxity and debility of these organs, coffee is of much service; and it has been stated by some writers that calculous complaints have diminished since its more extensive use.

Cafeine has not yet been used in medicine, but Geiger justly anticipates that a principle so rich in nitrogen will be found to be an important medicinal agent.

A beautiful green, which is unchangeable, and resists the action of acids, light, and moisture, may be precipitated from a decoction of decayed coffee, by means of pure soda. [Caffeic Acid.]

COFFEE TRADE. (French, *Café*; German, *Koffe*, *Koffebohnen*; Dutch, *Koffy*, *Koffebomen*; Italian. *Caffé*; Spanish, *Café*; Turkish, *Chaube*; Swedish, *Koffe*; Russian, *Kofé*.) It appears from estimates carefully formed, that the quantity of coffee annually exported from the various countries where it is grown cannot be much under 120,000 tons. This great branch of commerce has been wholly created since the beginning of the eighteenth century. Nearly all the coffee which now comes to Europe is the produce of trees propagated from a single plant, which having been raised from seed procured from Mocha in Arabia by Van Hoorn, governor of Batavia, was sent by him to the botanical garden at Amsterdam, and the progeny of which was, in the year 1718, twenty years after its reception from Java, sent to Surinam. The following statement exhibits as near an approximation as can be made to the quantities which on an average are shipped from the different places of its production:—Brazil, 72,000,000 lbs.; Cuba, 64,000,000; Hayti, 40,000,000; Java, 32,000,000; British West Indies, 25,000,000; Dutch Guiana, 10,000,000; States of South America, 8,000,000; French West India Colonies, 4,000,000; Porto Rico, 4,000,000; Sumatra, 3,000,000; Ceylon, 2,000,000; Bourbon, 2,000,000; Manilla, 2,000,000; Mocha, 1,000,000:—total, 269,000,000 lbs., or 120,000 tons.

The quantities ascertained by official documents to have been imported in one year into different countries are—France, 29,650 tons; United States of America, 46,070, Trieste, 9000; Hamburg, 20,620; Antwerp, 10,000; Amsterdam and Rotterdam, 8530; Bremen, 4,500; St. Petersburg, 2000; Norway and Sweden, 1470; Denmark, 1400; Spain (from Cuba only), 1000; Prussian Ports, 930; Naples and Sicily, 640; Venice, 320; Fiume, 170; United Kingdom, 18,250 (average of ten years):—total, 154,550 tons.

These quantities evidently do not comprise the whole amount of coffee that passes annually between different countries; it is not possible to ascertain that total quantity, because no records of their trade are published by some governments. On the other hand some proportion of the imports as given above are again exported, and appear more than once in the list; which for this reason, deficient as it is, yet exhibits a larger quantity than the whole presumed exports from the countries of production.

The imports, exports, and consumption of coffee in and from the United Kingdom in each year, from 1820 to 1835, have been as follows:—

	Imported. lbs.	Exported. lbs.	Taken for Consumption. lbs.	Rate of Duty, per lb. s. d.
1820	48,841,626	44,440,869	7,103,409	On Foreign Coffee 2 6 ,, East India . 1 6 ,, Brit. Plant. . 1 0
1821	45,237,869	41,635,956	7,593,001	
1822	44,003,124	35,825,535	7,669,351

1828	41,069,731	23,785,930	17,127,633	
1829	39,071,215	23,023,410	19,476,180	
1830	40,952,163	20,087,994	22,691,522	
1831	43,007,828	22,485,474	22,740,627	
1832	50,225,939	25,719,742	22,952,527	
1833	34,426,109	15,349,578	22,741,954	
1834	41,865,111	15,250,480	23,785,095	
1835	28,398,493	13,346,537	23,295,046	

It appears from these figures that the reduction of the duty in 1825 was followed by an immediate and rapid increase in the consumption, which rose from 8¼ millions of pounds in 1824 to more than 22½ millions in 1830. At this point, the consumption having overtaken the supply of those kinds which were admissible at the lowest rate of duty, the progress stopped short, and the consumption has since remained almost stationary. To remedy this disadvantage, the duty on coffee, the produce of British possessions in India, was at the end of 1835 reduced to an equality with the rate charged on coffee of the British plantations; but it appears doubtful whether the benefit of the revenue will not before long require that the duty on coffee of foreign growth should also be brought more nearly to an equality with that charged on other kinds, which are now effectually shut out from the English market by a discriminating duty of 84*s*. per cwt.

The effect of equalizing the duties upon East India and British plantation coffee has been to increase the total consumption of the kingdom to the extent of 1,783,244 lbs. during the first eight months of 1836, as compared with the corresponding period of 1835; which rate of increase, if continued throughout the year, will raise the annual consumption to 26 millions of pounds, or more than three times the quantity used before the reduction in 1825.

The price in London of fine Jamaica coffee in the beginning of each year, from 1820 to 1836, has been as follows:

1820 .	133*s*. per cwt.	1826 .	100*s*. per cwt.	1832 .	100*s*. per cwt.
1821 .	121 ,,	1827 .	95 ,,	1833 .	84 ,,
1822 .	109 ,,	1828 .	80 ,,	1834 .	112 ,,
1823 .	134 ,,	1829 .	76 ,,	1835 .	125 ,,
1824 .	120 ,,	1830 .	78 ,,	1836 .	120 ,,
1825 .	102 ,,	1831 .	78 ,,		

The quantities of coffee subject to different rates of duty, which were imported, re-exported, and consumed in 1835, were as under·

	Imported. lbs.	Re-exported. lbs.	Consumed. lbs.
Of British Plantations .	14,617,046	200,258	17,696,199
,, East India . .	7,167,914	2,616,881	5,596,791
,, Foreign Plantations .	6,613,533	10,529,398	2,126
Total . .	28,398,493	13,346,537	23,295,046

The net revenue derived from this source in 1835 was 652,123*l*.

Nearly one half of the exports in that year were made to the Netherlands· viz., to Belgium 4,671,861 lbs., and to

Holland 1,777,931 lbs. Italy took 1,735,103 lbs., other ports in the Mediterranean 1,301,836 lbs.; Germany, 1,263,447 lbs.; Russia, 1,342,254 lbs.; Denmark, 629,167 lbs.; and Norway, 310,459 lbs. The shipments to other countries were individually of inconsiderable amount.

COFFERDAM, called by the French Batardeau, is a wooden enclosure formed in a river in order to obtain a firm and dry foundation for the piers of a bridge. The Cofferdam consists of piles, which are squared beams of wood, pointed at one end and shod with iron, and surrounded at the top with an iron collar; these piles are driven into the bed of the river, and being braced together, form a wall of wood. The piles are sometimes grooved and tongued together; in other cases they are driven at short distances apart, and boards are let into the grooves formed down their sides. Two such enclosures are formed, one within the other, and the space between the two is filled with clay or chalk rammed down hard. The water in the inner enclosure is then pumped out, and the object for which the cofferdam was constructed is attained.

If the river is rapid and deep, it will be necessary to use several rows of piles in forming these wooden walls. Cofferdams have been constructed of the depth of forty-five feet in the water.

In lieu of cofferdams, caissons have been sometimes employed. Caissons are enormous boxes framed of wood, and made water-tight; the sides are so constructed, that after the piers are built they can be detached, the bottom only remaining as a foundation. The largest caissons ever constructed were those of Westminster Bridge, framed with 150 load of fir timber each. For a correct view of the interior of a cofferdam, see No. 275 of the 'Penny Magazine,' in which there is a view of the cofferdam employed for the repair of Blackfriars Bridge. Alberti is, we believe, the earliest writer on cofferdams.

COFFIN, the box or chest in which dead bodies are put into the ground; also in modern English a mould of paste for a pie: from the Latin *cophinus*, and that from the Greek κόφινος, which properly meant a wicker basket. Wyntown, in his 'Chronicle,' uses *cofyne* for a shrine or box. The kistvaen, or coffin composed of rough stones, set edgewise at the sides and ends, and covered with one or more flat stones, was common among the Britons, and a few such are still seen in Wales. Stone coffins are frequently discovered in barrows which also contain Roman urns, proving their use in England at that period. Sir Christopher Wren found such of the Saxon times, at the rebuilding of St. Paul's: and Gough adds that, from the ninth century to the reign of Henry III., stone coffins were in general use, that is, for persons of the higher classes. The bodies of the common people, not only in the Norman but also in the English æra, as we see in the illuminations of antient missals, were only wrapped in cloth, and so put into the ground. In this manner, Matthew Paris informs us, the monks of St. Alban's were buried, till the time of Abbot Warin, who died in 1195. He ordered that they should be buried in stone coffins, as more decent. Matthew Paris, on this occasion (*Vit. Abb. S. Alb.*, p. 95), charges him with innovations on established customs, to please the multitude. Strutt says, in the reigns of Henry V. and VI., stone coffins were made with necks, distinguishing the head and shoulders. Coffins both of lead and wood are of early use. The former occur in numerous instances through different centuries: and that the Saxons buried in coffins of wood, occasionally, we have the testimony of Bede. Ceadda was so buried (*Hist. Eccl.*, l. iv., c. 3), as was Etheldreda, wife of Egfrid, king of the East Angles. (*Ibid.*, l. iv., c. 29.) Sebba, king of the East Saxons, was buried at St. Paul's in a coffin of grey marble. (*Ibid.*, l. iv., c. 11.) The forms and ornaments of various antient coffins, mostly of stone, may be seen in the plates of illuminations in Strutt's *Manners and Customs*, vol. i., pl. xxxix., xlv., lxvi., and in Gough's *Sepulchral Monuments*. We have a remarkable instance of the use of the word coffin for an ordinary chest, in the Wardrobe Accounts of King Edward IV., 8vo. Lond., 1830, p. 125:—'For closyng and fastenyng of divers *cofyns* of fyrre, wherein the kyng's books were conveyed and caried from the king's great wardrobe in London to Eltham, v^{d}.'

COG. [Wheel.]

COGNAC. [Brandy. Charente.]

COHESION (*co-hærere*, to hold together) means the common phenomenon of the adherence or coherence of particles of matter, by which they form collective masses, requiring the application of more or less force to separate the parts.

According to the common notion entertained of matter, it is solid, or at least composed of particles which come into absolute contact. If we could substantiate the first supposition, it would still be apparent that the term *force of solidification* must take the place of *force of cohesion*, and give rise to inquiries into its quantity and mode of action: and even if we could imagine absolute contact of particles, we should find it necessary to append a notion of some force by which particles in contact remain in contact when some of them are put in motion, so as to draw the rest after them. But the balance of probabilities is very strong indeed against the supposition that matter is composed of particles in contact; so much so, that we are almost entitled to conclude it to be composed of particles separated by interstices of much greater dimensions than the particles themselves. If any one should assert the particles of the densest matter to be as far apart in proportion to their bulk as the bodies of the solar system, it would be impossible to bring any direct evidence in contradiction.

Such being the case, we may ask—1. What is the force of cohesion? for such a force there certainly is. 2. What is that law of action by which the particles of bodies are not drawn into absolute contact, but compelled to remain separate, and yet prevented from separating indefinitely?

With regard to the first question, it is most probable that as two bodies approach each other, a strong repulsive force is the cause of the first phenomenon which is perceived. When one billiard ball strikes another, we have no evidence, except that of our senses, of absolute contact taking place: that is to say, we only know that the first visible action takes place when the distance of particles is too small for the eye to perceive. All the evidence which is at all conclusive, is against the supposition of such contact being produced: and we are obliged to admit that our explanation must end in the statement that, arise from whence it may, there is a power in matter by which other matter is repelled, and which begins to act before contact has taken place. But if two pieces of solid matter be pressed together with great force, it would seem as if the particles would thereby be brought within a degree of nearness at which an attractive force begins to act. Two bits of lead pressed together remain in coherence even in a vacuum; and metal plates can be hammered together until the cohesion is as strong as if they had been naturally united.

The cohesive force is an absolute phenomenon, but if we suppose the particles of matter not in contact, it then becomes necessary to admit a new repulsive force, of which the sphere of action is interior to that of the cohesive force. Complete interstices can only exist upon the supposition that, at a certain distance, the cohesive force is destroyed, or at least overcome, by a counterbalancing repulsion. From the known effects of heat, it is supposed that caloric, a name which indicates the cause of heat, plays a prominent part in the production of the repulsion. Nothing positive, however, has yet been established on this subject: we can only make use of phenomena as they exist, to overturn the common impressions, by means of which *force*, the great agent of the universe, meaning the cause of visible display of motion excited or motion prevented, is postponed to notions of *matter*, or *impenetrability*, or similar words, which, if made accurate by close attention, and freed from such latent assumptions as arise from the unassisted senses, will be found to amount to the same idea.

In the article Attraction we had to deal for the most part with assumed forces, of which the effects are seen to coincide with the case of nature only by long and difficult mathematical deduction. In treating of attraction of cohesion we have the indications of real physical attraction [Attraction] in a less difficult form. The arguments against absolute contact are almost insuperable: if we yield to them, we are immediately obliged to admit that particles really act on each other at a distance. Nor will any suppositions as to caloric afford us the means of avoiding such a conclusion. If caloric be matter, we must first explain *its* cohesion or repulsion before we can apply it to explain that of other matter: if caloric be not matter, we gain nothing in the way of avoiding difficulty; for an agent which is not matter, but something else, with new properties superadded to the common and visible properties of matter, is as difficult as ordinary matter with the express addition of power over other matter at a distance. And it must be observed, that if we are rationally compelled to allow such power to a particle upon a particle, there is no new difficulty in the attraction of *gravitation*. If A can act upon B at the millionth part of an inch, there is no *à priori* difficulty in the notion that two A's together can act on B at twice the distance with as much visible effect as a million of A's collected can act at a million of times the distance, and so on. It must not however be supposed that we mean to infer that gravitation and cohesion are both referable to the Newtonian law of attraction: all that is assumed in the latter refers to particles or masses supposed to be at sensible distances from each other, without either affirming or denying anything as to the modifications which the law may undergo at distances so small as never to be subjects of consideration in comparing one planet with another, or one leaden ball with another, as in Cavendish's experiment. [ATTRACTION.]

We may make it apparent to the mathematician that laws of attraction may very easily be expressed which shall combine the leading circumstances connected both with gravitation and cohesion in one formula. Let us suppose, for instance, that at the distance r, the accelerating force of two equal particles on each other is expressed by

$$\frac{a}{r^n}\left(1-\frac{b}{r}\right)\left(\frac{c}{r}-1\right)+\varepsilon^{-\frac{m}{r}}\cdot\frac{n}{r^2}$$

positive values denoting attraction, and negative values repulsion. If a and m be made sufficiently small, the first term may be made insensible at all finite distances, and the second as near as we please to the Newtonian law. But when r is very small, the second term becomes insensible, and such a value may be given to n that the first term shall be of sensible value, as follows: Let c be greater than b, both being quantities of that order of smallness at which the Newtonian term becomes insensible. Then when r is little greater than c, the first term is negative; when r lies between c and b, it is positive; and when r is less than c, it is negative again.

The solid, fluid, and gaseous states of matter show the rise and progress of a repulsive force generally produced by the action of heat. In the first, the particles absolutely attract, in the third they absolutely repel, each other; but in the second the repulsive force almost counterbalances the attractive force, leaving only enough to create that weak degree of cohesion which exists in fluids, or at most that semi-cohesion which is observed in birdlime, in gum-water, and the like. The transition from complete solidity to the gaseous state appears to be made through various degrees of fluidity, and the gradual hardening of melted sealing-wax is a familiar instance of a part of the gradation.

It is impossible to do more than point out the manner in which leading phenomena are explicable on the notion of attraction and repulsion. Mathematical analysis is not yet sufficiently powerful to enable us to say whether such a formula as we have enunciated above could be made to give the numerical phenomena of cohesion.

The practical considerations connected with cohesive forces will be treated under the usual heading [STRENGTH OF MATERIALS].

COHORT was a division of the Roman legion. The term (cohors, or chors, the Greek χόρτος) originally signified an enclosure for sheep or poultry, and was afterwards used to designate the number of men which could stand within such an enclosure. The Roman legion, as well as the citizens at the census [CENSUS], was subdivided into centuries. A century did not always consist of a hundred: the number varied. A legion consisted of ten cohorts; each cohort contained three maniples, and each maniple two centuries; hence there were thirty maniples and sixty centuries; and in the whole legion there must have been sixty centurions. The different centurions received names indicative of their rank. Of the two centurions in a maniple, one ranked before the other, and had the title prior; the second was called posterior. The first centurion of the first maniple had the charge of the eagle, the great standard of the legion: he was ranked with the equites. He was called centurio primi pili (*Livius*, xxv., 19), or simply primus centurio, or primus pilus (*Cæsar*, *De Bell. Gall.* ii. 25). The office was lucrative, but it was not always the reward of merit: favour or money in some cases procured it (*Cicero*, Pis. 36); under the emperors it was bestowed generally from caprice (*Vegetius*, xi. 3, in Pitiscus, *Lexic. Antiq. Rom.*) The badge of a centurion was a vine rod, which the soldiers sometimes felt (Tacitus, *Ann.* i. 23).

The cohortes alares, or alariæ (*Liv.* x. 40, 43), were the troops of the auxiliaries and the allies which were stationed in the wings (alæ).

The cohors prætoria was a select band which usually attended the prætor (Sallustius, *Catil.* c. 60); (Pitiscus, *Lexicon Antiquit. Rom.*, *in Cohors, Centurio.*)

COIMBATORE, a province situated in the region of the Eastern Ghaut mountains, in the South of India, about the 11th degree of north latitude, and bounded on the north by Mysore, on the west by Malabar, on the south by Dindigul, and on the east by Salem and Trichinopoly. The length of the province from north to south is 50 miles, and its breadth from east to west about 45 miles. The surface of the country varies exceedingly. Towards the south the level is not more than 400 or 500 feet above the sea, but it gradually rises towards the north, and even in what is considered the low country the level rises to 900 feet above the sea. About 11° 35′ N. lat., the mountains called the Eastern Ghauts occur; the Kumbetarine hill, in 11° 35′ N. lat., and 77° 20′ E. long., is reckoned to be 5548 feet above the level of the sea. Some summits of the Neelgherry mountains, which are in the north-west part of the province, and unite the Eastern and Western Ghauts, are still higher: one of the peaks called Moorchoorti Bet is 8800 feet above the sea. The soil is generally dry, but in the south there is some marshy ground. The low country is effectually sheltered from the violence of the south-west monsoon. The climate is considered healthy, and in particular the Neelgherry mountains are resorted to by Europeans resident in India for the recovery of their health. In these hills the mean temperature in April and May is 65° Fahrenheit. During the cold season the thermometer sometimes sinks to the freezing point, when the air is peculiarly clear and elastic, and produces a cheering effect upon the spirits. Coimbatore is watered by the rivers Bhavani, Amaravati, and Cavery, the first and second of which fall into the Cavery; the Bhavani, at Bhavani-Kudal, 58 miles north-east from the town of Coimbatore, in 11° 26′ N. lat., and 77° 44′ E. long., and the Amaravati about 10 miles below the town of Caroor. These rivers are filled by both monsoons; by the south-west in June, July, and August, and by the north-east in October, November, and December. The extent of land under cultivation in 1814-15 was 960,000 acres, and in 1825-26 was increased to 1,451,439 acres. Up to the former period the land revenue of the province was collected under the village system, but a permanent assessment being then made, not only upon every farm, but upon each field, and the ryots being confirmed in the possession of their lands, the improvement here noticed began. The government has fully participated in this advantage; in 1814-15 the land revenue was 18,64,391 rupees, and in 1825-26 had advanced to 23,79,633 rupees, being an annual increase of 51,524*l.* In 1814-15 the government assessment was considered to be equal to one-third of the gross produce of the soil, and in 1825-26 it did not exceed one-fifth; the price of land during that time was doubled. The population of the province in 1828 was 870,866; in 1823 it was stated to be 638,199; but in this latter number children under five years of age were not included. The means for education provided by the government are miserably deficient. According to the latest returns, the whole number of scholars was only 8930, of whom 8618 were Hindus, including 82 females, and 312 were Mohammedans.

The principal places in the province, in addition to the capital, Coimbatore, are, Animalaya, Aravacourchy, Bhavani-Kudal, Caroor, Daraporam, Erroad, Palachy, Satimangalum, and Sivana Samudra. Animalaya is on the west side of the small river Alima, in 10° 31′ N. lat., and 77° 1′ E. long. This town, which contains about 400 houses, is the common thoroughfare between Malabar and the southern part of the Carnatic. A fort stands at a short distance west of the town, and had fallen into decay, when, to provide materials for repairing it, Tippoo pulled down five large temples. The forests in the neighbourhood contain abundance of fine timber, which is of little value from the want of means for transporting it. Aravacourchy, the seat of Arava, so called from the name of the founder, is situated in 10° 41′ N. lat., and 77° 54′ E. long. The town was destroyed towards the end of Hyder's reign, by an English force under Colonel Laing, but it has since been rebuilt, and at the beginning of the present century it already contained 250 houses, and was fast increasing: the inhabitants mostly speak the Tamul language. Bhavani-Kudal, at the confluence of the Bhavani and Cavery rivers, contains two celebrated temples, one dedicated to Vishnu and the other to Siva, and is considered a place of great sanctity by the Hindus. Caroor, on the north side of the Amaravati river, in 10° 53′ N. lat., and 78° 4′ E. long., is a considerable town, and contains 1000 houses; it was formerly a place of great commercial activity, but its trade has long since been greatly diminished. Daraporam, or more properly Dharma-puram, is a populous town situated in an open country near the Amaravati, in 10° 37′ N. lat., and 77° 35′ E. long. The streets are wide and regularly laid out, and many of the houses are spacious. Erroad was a very considerable place during Hyder's reign, and contained 3000 houses; under the government of his successor it was much reduced; and during the invasion of the country by the English under General Meadows, the town was in a great measure destroyed. It has since been partially restored, and has been made a military station. Palachy is a small but thriving town, situated in a well-cultivated country, in 10° 39′ N. lat., and 77° 6′ E. long. Some coins of Augustus and Tiberius have been dug up in the vicinity. Satimangalum, a town and fortress, in 11° 31′ N. lat., and 77° 16′ E. long., contained, in Hyder's reign, about 800 houses, but the number has since been much reduced. The fort is large, and the town is built in a straggling manner about the plain; it contains a large temple dedicated to Vishnu. This place is considered unhealthy, and the air is mostly intensely hot. The island of Sivana Samudra, formed by the Cavery, is the site of the antient Hindu city of Gunga Raja; two cataracts are here formed by the Cavery, one on its northern and the other on its southern arm. [CAVERY.] The city of Gunga Raja, supposed by Dr. Buchanan to have been founded not more than 300 years ago, is now completely destroyed; the southern gate of the wall by which the city was surrounded may still be seen, and one principal street, about a mile in length from north to south, may be traced: there are besides visible the ruins of several Hindu temples, in one of which is a colossal statue of Vishnu; but the whole place is choked by jungle, and occupied by banyan and other forest trees.

A considerable quantity of dry grain is raised in the province; cotton and sugar are likewise cultivated, and weaving is carried on extensively.

This province was acquired by the British from the rajah of Mysore in 1799.

(Rennell's *Memoir of a Map of Hindustan*; Buchanan's *Journey through Mysore, Canara, and Malabar*; *Report of Committee of House of Commons on the Affairs of India*, 1832.)

COIMBATORE, the capital of the province, in 10° 52′ N. lat., and 77° 5′ E. long., is a well-built town, containing about 2000 houses, being little more than half the number which it contained under the government of Hyder Ali. His son Tippoo sometimes resided at Coimbatore, where he built a mosque. About two miles from the town, at a place called Peruru, is a celebrated temple dedicated to Iswara, and called *Mail* (high) *Chitumbra*, to distinguish it from another Chitumbra near Pondicherry. The idol is said to have placed itself here at a very remote period, and about 3000 years ago the temple was built over it by a rajah of Madura. This building exhibits a profusion of Hindu ornaments, but is destitute of elegance, and the figures are not only rude, but many of them indecent also. This temple was plundered of its gold and jewels by Tippoo, who excepted it, however, from the general order which he issued for the destruction of all idolatrous buildings; and although its splendour was then destroyed, the Brahminical worship has always been continued.

The town was taken by the English in 1783, but was restored at the peace in the following year. It was again taken by the English in 1790, and retaken by Tippoo's general, but was transferred with the province to the British government in 1799, and has since remained in their possession. The travelling distance from Seringapatam is 122 miles, and from Madras 306 miles.

(Rennell's *Memoir*; Mill's *History of British India*; Buchanan's *Journey through Mysore*, *&c.*)

COI'MBRA, a town and bishop's see in Portugal, in the province of Beira, and the chief town of a comarca, or administrative division. It lies on the slope of a hill on the right or north bank of the Mondego, about 120 miles N.N.E. of Lisbon, and 25 N.E. of the seaport of Figueiras at the mouth of the Mondego, in 40° 12′ N. lat. and 8° 17′ W. long.

A fine bridge connects the town of Coimbra with the splendid and extensive monastery of Santa Clara, situated with its gardens upon a hill on the south bank of the Mondego. To the north-east of Coimbra rises the high ridge of Busaco, and on the west and south-west a fertile but marshy and unwholesome plain extends towards the sea. The town is old-fashioned, and most of the streets are narrow, steep, ill-paved, and dirty. There are, however, several fine buildings, such as the palace of the university, once the residence of the kings, and the various colleges connected with it, the cathedral, besides other churches and convents, and several squares adorned with fountains, which are supplied through a fine aqueduct adjoining the town. The university was transferred to Coimbra from Lisbon by King Denis in 1308. It was afterwards removed again to Lisbon, but John III. transferred it again to Coimbra in 1537. In 1653 King John IV. issued regulations for the university, 'Estatutos da Universidade de Coimbra,' printed in 1654. Pombal, in 1733, effected several useful reforms in the system of instruction, and added the faculties of mathematics and natural philosophy to those of theology, canon and civil law, and medicine, already existing. He also gave to the university several buildings belonging to the suppressed order of the Jesuits. No student is permitted to attend a course of lectures in any of the faculties without having first undergone one year of preparatory study in the Royal College of Arts. The course of theology lasts five years. The same time is allotted to the canon and civil law, after which the student can obtain his Bachelor's degree, which qualifies him for the bar, or for inferior appointments in the magistracy. In order to obtain the degree of Doctor a sixth year is required, after which the candidate undergoes a private examination. In the faculty of medicine eight years' attendance are required, and an additional year for the Doctorship. The course of philosophy lasts four years. The lectures begin in the autumn and last till May, after which the public examination takes place till July, followed by three months' vacation. The public examinations are in Portuguese, and are said to be very severe. The university is very rich, and the emoluments of the professors are respectable, besides which they have the prospect of preferment in the civil and ecclesiastical departments. A Doctor's degree in the university is a necessary qualification for the higher stations in the church and magistracy.

The government of the university is vested in a council, consisting of the rector, who is appointed by the king for a limited time, the deans of the various faculties, two sindicoes or fiscals, and a secretary. The financial administration is intrusted to a separate council, 'Junta de Fazenda,' consisting of three professors, a treasurer, and a clerk. The library of the university occupies three large halls filled with books chiefly of antient date. It is opened every evening, for the use of the students, at the conclusion of the public lectures. The library of the Benedictine convent is better both in number and choice, and contains works of more modern date. The lectures on canon and civil law are the most attended to, on account of the great demand for law graduates for civil offices in the various towns of the kingdom. The average number of academical students is said to be about 1200. The medical students use French and English works. The lectures are generally gratuitous. The annual necessary expenses of a student during his nine months' attendance are equivalent to about 30*l.* sterling. There is a botanical garden, a museum of natural history, with a collection of minerals, a chemical laboratory, and an observatory well furnished with instruments. (Kinsey, *Portugal Illustrated*, 1828.) The large monastery of Santa Cruz, in the lower part of the town, contains the monument of Affonso Henrique, the founder of the monarchy, and other early kings. In the great hall of the university, where the public examinations and disputations are held, is a complete collection of the portraits of the Portuguese kings; and the apartment where the candidates for the Doctorship undergo their last examination in private contains the portraits of the successive rectors of the university. (*Ibid.*)

Coimbra has 19,850 inhabitants distributed into eight parishes, an hospital, a house for the poor, and a Magdalen. It has several manufactories of pottery. The civil magistrates are the Corregidor and seventeen Juezes de Fora. (Miñano, *Diccionario Geografico, & Suplemento.*)

The immediate neighbourhood of Coimbra is delightful, and filled with gardens and quintas, or country-houses. The tract of country between it and Condeixa, south of the Mondego, is styled the fruit-basket of Portugal. In the same direction, not far from the convent of Santa Clara, is the Quinta das Lagrimas, in a romantic sequestered spot, where Donna Inez de Castro is reported to have been murdered. (Camoens, *Lusiadas.*)

Conimbrica, the antient Coimbra, is said to have been built by the Romans, though at some distance from the present spot; but Miñano asserts that its name is of Arabic origin. Others say that the present town was first built by Ataris, one of the Gothic kings. The view of the town from the south bank of the river is very fine, the summits of the heights above being covered with convents and public buildings. Coimbra lies on the high road from Lisbon to Oporto, and its fine bridge affords the principal means of land communication between the north and the south provinces of the kingdom.

COIN: metal stamped for currency; derived by some from the Greek *κόινος, common;* by others from the Latin, cuneus, *a wedge;* the first currency of metal, in all probability, being in the form of wedges, or ingots. Commerce, in the earliest periods, was carried on by the mere exchange of articles, and it is remarkable that throughout the early part of Scripture, as well as through the poems of Homer, not a single passage occurs from which we can infer either the use or the existence of stamped money. Metals, however, being close and compact in form, universal as to use, and admitting of division into larger or lesser parts, soon became the representatives of value, though at what exact period remains in doubt. Herodotus, i. 94, speaking of the Lydians, expressly says they were the first people on record who coined gold and silver into money. The Parian Chronicle, however, ascribes the origin of coined money to the Æginetans, under Pheidon, king of Argos, 895 years before Christ. Ælian, in his 'Various History,' corroborates this statement as far as the Æginetans are mentioned: and our best numismatic antiquaries agree in considering the coins of Ægina, from their archaic form and appearance, as the most antient known. They are of silver, and bear on the upper side the figure of a turtle, and on the under an indented mark, as if the metal, at the time of striking, had been fixed upon a puncheon, and from the weight of the blow had received a deep cleft. In later coins of Ægina, the turtle has been changed to a tortoise, and the fissure on the other side converted into a device. The coins of Lydia probably come next in point of antiquity, and then the early Darics of the Persian kings, which occur both in gold and silver, and bear a strong resemblance to the coins of Ægina in the mode of striking: these, if they are to be referred to Darius the First, must have been coined between B.C. 522 and 486. The richer the metal, the smaller and more portable was the quantity required for the coin. There are coins in gold of the early kings of Persia, similar in type to the silver Darics, and of very minute size.

The study of coins is not to be considered as the province of the antiquary alone. Coins are among the most certain evidences of history. In the later part of the Greek series they illustrate the chronology of reigns. In the Roman series they fix the dates and succession of events. Gibbon observes that if all our historians were lost, medals, inscriptions, and other monuments, would be sufficient to record the travels of Hadrian. The reign of Probus might be written from his coins. In illustrating the history and chronology of sculpture and antient marbles, coins enable the scholar and the artist not only to discern those peculiarities which characterise style, as it relates to different ages and schools, but to ascribe busts and statues to the persons whom they represent. The personation of the different provinces, too, forms another point of interest upon the Roman coins. Coins are frequently essential to the illustration of obscure passages in antient writers; and preserve delineations of some of the most beautiful edifices of antiquity not existing now even in their ruins. Addison, in his 'Dialogue on the Usefulness of Antient Medals,' has long convinced the world of the connexion of this science with poetry. As a branch of the fine arts, it may be sufficient to say that some of the medals of Sicily belong to a period when sculpture had attained its highest perfection. We would particularly refer to the coins of Syracuse. In every quality of art, too, the Roman coins, to a certain period yield to the Greek alone. From Augustus to Hadrian the Roman mint was the seat of genius: and coins of admirable execution are found even down to the time of Posthumus.

The generality of numismatic writers divide coins into Antient and Modern;—the Antient, into the great divisions of Greek, Roman, and Barbarian.

The *Greek* they divide into cities and kings. Of the first they can make no chronological arrangement: it is alphabetical, under the different countries. The kings commence with the age of Alexander the Great, and belong to the four kingdoms into which his empire was divided, besides the kingdom of Epirus. This series, in a chronological point of view, closes with the extinction of the dynasty of the Lagidæ in the Augustan age. The coins of the Greek cities were impressed either with appropriate symbols or the heads of deities. The coins of the monarchs bore the heads of the respective princes. Pinkerton observes that the first copper coins of Greece known are those of Gelon king of Syracuse, about 490 years before our æra. These were called Chalci, pieces of brass; others, of a more diminutive size, were called Lepta, or Kerma, as being change for the poor. He considers there is no proof of the coinage of gold in Greece before Philip of Macedon. Athens had no gold money at the beginning of the Peloponnesian war.

The *Roman* coins are divided into consular, imperial, and medallions. The subdivisions of the consular are into Roman asses and coins of the families. Of the imperial there are two subdivisions, Roman and Grecian; the latter being again subdivided into those of provinces, colonies, and municipia. The medallions are likewise divided into Roman and Grecian. The earliest coinage of Rome was of copper, and took place in the reign of Servius Tullius, probably about five centuries before Christ. The Romans are supposed to have borrowed the art from their neighbours, the Etruscans. Of the as, its divisions and its compounds, we have already spoken in a former article. On some of the later Roman, as well as on what were called the Italian asses and their parts, the practice became prevalent of placing the names of many of the principal families of Rome upon the fields of the coins. These form the division which are called family coins. The silver coinage of Rome was introduced in the year 266 before Christ, when the denarius was so termed from its being equivalent to ten asses. Pliny informs us (*Nat. Hist.* xxxiii. 13, edit. Hard. ii. 612) that the coinage of gold was introduced sixty-two years after that of silver. The largest piece of gold was called aureus. [AUREUS.] The imperial coins of Rome form the most complete and most interesting series of any extant. Those of copper being found of different sizes, are distinguished into first, second, and third brass: in historical importance, as well as for the devices, the largest series is to be preferred. The largest imperial brass coin was the sestertius, and from the Augustan age went by the name of nummus, or æreus. It was worth twopence English. All the large brass coins are of yellow metal; the middle brass, yellow and red; the small, mostly red. No sensible diminution of the sestertius took place till the reign of Alexander Severus, when it lost upwards of a sixth of its weight, and continued to diminish till the reign of Gallienus, when it totally vanished. In this reign the chief copper coins in use were the small brass, or assaria, which, according to the writers of the Lower Empire, were at last numbered at sixty to the silver denarius. Under Valerian and Gallienus, copper washed with silver appeared. In the reign of Diocletian, a coin denominated the follis supplied the place of the sestertius; but the denarii ærei continued quite common down to Constantine I. He introduced a new coinage, and then the follis had its changes and its subdivisions; but its appellation adhered to what had now become the largest brass coin of the Roman empire, to the very latest notices which we have of the Byzantine money. From the time of Augustus to that of Gallienus, the imperial or silver denarius contained sixteen assaria. Under Caracalla a larger denarius was struck, which had a third more, or twenty-four assaria, and was called argenteus: the common denarius of silver being then termed minutus. Under Gallienus however the minutus ceased, and argenteus and denarius then became only different names for the Roman silver coin, which at that time contained no less than sixty assaria. Constantine I. introduced the milliarensis, worth somewhere about a shilling of our money: but the argentei, or denarii, were struck as late as the reign of Heraclius. Aurei and semi-aurei were the sole pieces in gold for near three centuries. Till Sulla's time the aureus continued at thirty silver denarii. In the reign of Claudius, and afterwards, it went for twenty-five silver denarii. Under Philip, aurei of two or three sizes first appear, of a rude fabric; one class of which were called trientes. The weight originally given to the aureus was 120 grains; it afterwards fluctuated to between 80 and 90 grains, and was sometimes even of less weight. Constantine I. accommodated the aureus to his new coinage, and gave it the name of solidus, of six in the ounce of gold. The solidus passed for fourteen milliarenses. It went for rather more than twelve shillings of our money, and continued of the same standard to the very close of the Byzantine empire. The medallions were struck both at Rome and in the provinces, whence the division of this class into Roman and Grecian. The term is applied to all those productions of the Roman mint which exceeded the coins ordinarily current in size, whether in gold, silver, or brass. Though generally conceived to have been struck upon similar occasions to those on which we ourselves coin medals, there are still various circumstances which lead to the belief that they were intended for circulation as money. Medallions, says Pinkerton, from the time of Julius to that of Hadrian are very uncommon and of vast price: from Hadrian to the close of the Western Empire, they are less rare. The types of the Roman medallions are often repeated upon common coin. Those struck in the Grecian territories are the most numerous, and are distinguished from the Roman by their thinness and inferiority of workmanship. Many Roman medallions have S. C. upon them, as being struck by the senate; others have not, as being struck by order of the emperor. The Roman medals called Contorniati, it is the opinion of our first medallists, were no more than tickets of admission for different places at the public games.

The third class of antient coins, denominated *Barbarian*, consists of those of Lydia, Persia, Judæa, Phœnicia, Numidia and Mauritania, Carthage, Spain, Gaul, and Britain. The coins of Lydia and Persia have been already slightly noticed. The Darics, from their present extreme scarcity, are supposed to have been melted down for his own coinage by Alexander the Great, upon his conquest of Persia. Pinkerton asserts that all the real Darics were of gold, and that the silver coins with the archer (the same type) are later. Nevertheless many of the silver Darics are equally if not more archaic in appearance. Of Persian coins there is a second series, that of the Sassanidæ, beginning about A.D. 210, when Artaxerxes overturned the Parthian monarchy; they extend to the year 636, when Persia was conquered by the Arabian caliphs. The Hebrew coins were struck under the dominion of the family of the Maccabees, and chiefly in the time of Simon the high-priest, about the year 150 B.C. They are nearly all of copper, and extremely rude in workmanship; the legends are in Samaritan characters, and the symbols are those appropriate to the nation, such as a sprig, considered as Aaron's rod, sacramental cups, censers, &c. The Hebrew shekel, as it is called, is of silver, about the value of the Greek tetradrachm. Hebrew coins pretending to an earlier date than the Maccabees are spurious. The Phœnician coins are in no instance considered older than the time of Alexander the Great, and are chiefly referred to the cities of Tyre and Sidon. The Numidian coins are those of Juba I. and II. The Punic or Carthaginian coins are believed to have been struck by Greek artists. Those of Spain agree in character with the coins of the different nations by whom the several colonies of that country were planted, Phœnicians, Greeks, and Carthaginians; and many of them are inscribed with Phœnician, Greek, and Roman legends: a few others are met with, distinguished by what are called Celtiberian characters, not unlike the letters of the Runic and Etruscan alphabets. Of the coins of Gaul, the most antient have no legends at all; they have very rude devices, and many of them are in base gold: after the Gauls had intercourse with the Romans, some of their coins bear inscriptions which look like Latin, mostly in single words, and not of easy interpretation: they are not unlike many of those which are called early British. Cæsar describes the Britons as a people just emerging from barbarism, and no further acquainted with commerce than to have discovered that it could not be conducted by simple barter alone. His account implies, that however they might have known its use, the Britons had not proceeded so far as actually to coin money: although they had a substitute for it in pieces of brass, or iron rings, or plates regulated by weight. He says, 'Utuntur aut ære, aut annulis ferreis, ad certum pondus examinatis, pro nummo.' (*Bell. Gall.* v. 12.) The passage however is corrupt: for *annulis* some manuscripts read *taleis*, and others *laminis*. Coins however are found in this country which are usually attributed to the very early British kings, in gold, silver, and the inferior metals; ruder in fabric than they would have been had the Britons learned the art of coining them from the Romans. They are without legends, and many of them, like the early Gaulish coins already mentioned, have unintelligible devices: they seem to justify our antiquaries in thinking that Cæsar had not sufficient information to make his testimony quite conclusive. The use of a better sort of money was unquestionably taught the Britons by the Romans very soon after Cæsar's second invasion, when the types improved, and when no one who examines them carefully will doubt that Roman artists were employed upon the dies. The earliest coin which can, with the least appearance of probability, be attributed to any particular British monarch, bears upon it the letters SEGO, possibly for Segonax, one of the four Kentish monarchs who attacked Cæsar's camp at the time of the invasion we have just mentioned; it has also the word TASCIO upon it, which is seen upon numerous other coins which are undeniably British. Cunobelin was a later monarch of Britain, whose name is considered to be abbreviated upon the coins which have CVN, CVNO, and CVNOBELI upon them, together with the words CAMV and CAMVL, the leading letters of Camulodunum, his capital city, supposed to be either Colchester or Maldon in Essex. VER, as well as VERLAMIO at length, for Verulam, occur upon other coins of the same period. One has BODVO, which may or may not be a coin of Bonduca or Boadicea, queen of the Iceni. It is probable that the British coinage closed with the money of Cunobelin; for in a very few years after his decease the second subjection of Britain took place under Claudius, and was so complete and severe, that the country became rather a Roman than a British island. Gildas (*De Excidio Britanniæ*, c. v.) expressly speaks of a Roman edict which ordained that from that time that all money current among the Britons should bear the imperial stamp. That this prohibition was followed up by the establishment of Roman mints in Britain is highly probable: and certain initial letters, as P. LON. for *pecunia Londini*, &c., are brought forward as evidence of the fact; but most of these initials are equally applicable to other places in the Roman empire where mints were established, and therefore do not afford a proof quite so conclusive as is wanted. The coins of Carausius and Allectus, the seat of whose empire was in Britain, have a strong claim to be considered as the production of British mints. Those who wish to see under one view the 'Coins of the Romans relating to Britain,' will find the fullest information in a little volume recently published under that title by Mr. John Yonge Akerman, 12mo., London, 1836.

MODERN COINS are those which have been struck since the fall of the Western Empire; but it is impossible, in the space to which the present article is necessarily confined to enter into minute details respecting the series of coins in each country. We shall be brief in our notices of the greater part, that we may devote a larger space to the coins of England

The series of the coins of Italy under the Ostrogoths began soon after the year 480 of the Christian æra. The French series commences with Clovis, A.D. 490. That of Spain with Liuva, Prince of the Visigoths, soon after the middle of the sixth century, or about A.D. 567. The states of Germany appear to have struck money very shortly after the age of Charlemagne; as well as the independent Lombard cities, and the Neapolitans. The Papal series of money begins with Pope Hadrian I., A.D. 772. Denmark has coins of an early date, but few of them are intelligible before the time of Canute; contemporary with whose date are the coins of the petty kings of Ireland. In Sweden coinage is said to have begun under Biorno, A.D. 818; and in Norway with Olave or Olaf, A.D. 1066. The Russian coinage is of a later date than the other coinages of Europe. Of Scotland pennies exist ascribed to Alexander I., A.D. 1107: those of William the Lion, A.D. 1165, are numerous. Pennies were the earliest coins in most of the European kingdoms, and a prevailing device upon them was a cross.

The *Coins of England* form the most complete modern series extant. At what time the circulation of the Roman money ceased, we are ignorant: but Sceattæ (from the Anglo-Saxon ꞅceaꞇ, shot, money) are known of the early kings of Kent, some of which must have been struck within the sixth century; and there are others so similar to them in type as to justify their appropriation to the same people, but which from their symbols were evidently coined before their conversion to Christianity. They are too rude generally to admit of description, are of silver, and found of different weights, from seven grains and a half troy to twenty and upwards: their most common weight is from fifteen to nineteen grains. Several plates of these coins are engraved in Ruding; they appear to have been current chiefly from the year 500 to 700. A sceatta of Ethilberht I. of Kent is the earliest Saxon coin which can be appropriated: he reigned from A.D. 561 to 616. Sceattæ also are the only coins which have hitherto been discovered of Ecghbert, king of Kent, who reigned from 665 to 674. In point of antiquity the penny succeeds; the name of which first appears in the laws of Ina, king of the West Saxons, who began his reign in 688. The word has had numerous etymologies; but that from *pendo*, to weigh, seems the most reasonable: it was then, as it still is, the 240th part of the nummary pound. The half of the penny, called helꝼlinᵹe or halꝼpeniᵹe, and the fourth part or ꝼeoꞃðunᵹ, farthing, are mentioned in the Saxon gospels; and a Saxon halfpenny of Edward the Elder is said to exist in the Bodleian collection at Oxford: but we know little more of the earliest divisions of the penny. The coin ascribed as a penny to Ethilberht II. king of Kent, between 749 and 760, with Romulus and Remus on the reverse, is beyond doubt a forgery. As to the rest of the kingdoms of the Heptarchy, no coins have yet been discovered of the South Saxon monarchs. Of the West Saxon kings, we have coins of Athelheard, A.D. 726; and of Beorhtric, who came to the throne in 784. Mercia seems to have been the most wealthy kingdom, and has a large series. It begins with Eadvald, who ascended the throne in 716, followed by Offa (whose queen Cenethreth or Quindred also enjoyed the privilege of coining), Egcberht, Coenvulf, Ciolvulf I., Beornwulf, Ludican, Wiglaf, Berhtulf, Burgred, and Ciolvulf II., with whose short reign the kingdom expired. The coins of the East Angles begin with Beonna, about the year 690; but in consequence of the temporary annexation of the kingdom to that of Mercia, we have but few coins of succeeding monarchs: those only of Aethelweard, 760, Edmund the Martyr, 855, and Ethelstan, 860, are known. The kingdom of Northumberland has this remarkable peculiarity belonging to its coinage, that from its mints issued, as far as is yet discovered, the only brass coins which were struck by the Anglo-Saxons. The earliest specimen hitherto known is of the reign of Ecgfrith, who ascended the throne in 670: it differs from the stycas of succeeding monarchs in the omission of the moneyer's name on the reverse. Of sixteen succeeding monarchs (whose reigns occupy more than a hundred and thirty years), no coins have as yet occurred. The first that appears was struck by Eanred, who began to reign in the year 808. One silver penny of Eanred is known. His stycas are of various rude types, without any representation of the monarch, but with a legend similar to that on his silver coin, excepting that the moneyer's name stands on the reverse, without any addition. Other stycas occur of Ethelred his son 840, of Redulf, and of Osbercht, whose reign began in 849. After his reign stycas seem to have fallen into disuse, at least none of a later period have yet been found. Stycas were also struck in the Saxon times by the archbishops of York: Ruding has engraved those of the archbishops Eanbald II., Vigmund, and Wulphere. One coin of Regnald, who was expelled the kingdom of Northumberland in 944, is known; and one of Anlaf, which has upon its reverse the Danish raven: these are pennies. Pennies also are known of Eric. At the beginning of the ninth century Ecgbeorht or Egbert ascended the throne of the West Saxon kingdom; and in the course of his long reign brought under his dominion nearly the whole of the Heptarchic states: he is therefore commonly considered as the first sole monarch of England, notwithstanding those states were not completely united in one sovereignty until the reign of Edgar. On his coins he is usually styled ECGBEORHT REX, and sometimes the word SAXONVM is added in a monogram within the inner circle of the obverse: some of his coins have a rude representation of his head, and some are without it. From Egbert's time, with very few exceptions, the series of English pennies is complete; indeed for many hundred years the penny was the chief coin in circulation. Of the Saxon pennies those of Alfred bear a considerable price; on some he is called AELBRED REX, on others ÆLFRED. Edward the Elder has Saxon buildings on the reverses of several of his coins; and on one of Athelstan's is a building intended for York Cathedral. The coins of Canute and of Edward the Confessor are among the most common of the Saxon series: those of Harthacnut are rare. English coins of Canute have frequently, and of Harthacnut in a few instances, been found in Denmark. Numerous coins of Canute and Ethelred II. have also been found in Ireland.

The archbishops of Canterbury, during a part of the Anglo-Saxon period, also coined money. Pennies exist of Jaenberht, archbishop of Canterbury, from 763 to 790; of Æthilheard, who died in 803; of Vulfred, who succeeded in that year; of Ceolnoth, who died in 870; of Ethered, 871; and of Plegmund, who sat from 891 to 923. In Athelstan's laws two moneyers are allowed to the archbishop of Canterbury, but no archiepiscopal coins of that reign are known, nor indeed any until the time of archbishop Bourchier, a space of several hundred years. Of Harold II.'s pennies there are three distinct types; two with the head looking to the left, the third, which is of very uncommon occurrence, with the head to the right; all have the word PAX in the centre of the reverse. Of the coins of William I. and II. the best account, with engravings of all the types, will be found in the 'Archaeologia,' vol. xxvi. p. 1—25. Of the types there exhibited, those which bear the strongest resemblance to the coins of the Confessor and Harold are ascribed with great probability to the first William; those which most resemble Henry I.'s coins to William II. The coins which present a sceptre on each side of the king's head, are universally ascribed to the Conqueror: those with two stars to William Rufus, the same ornament occurring upon his Great Seal. Most of them read PILLEM, PILEMV, OF PILLEMVS REX A, AN, ANGLO, OF ANGLOR; the P in Pillem being in reality the Saxon V (W). Of Henry I.'s pennies the types are as various as upon those of any monarch of the English series: the reverses bear the name of the mint and moneyer. This had been the Saxon practice, and it continued till the reign of Edward I. Our historians say that Henry I. coined halfpence and farthings; but none such are known in our cabinets. Through the Norman times, and certainly in the reign of Edward the Confessor, halves and quarters of the penny, regularly and nicely cut, to go as halfpence and farthings, occur almost whenever parcels of the coins of those periods are discovered. The troubles of Stephen's reign will account for the wretched state in which the pennies of that king occur: these, with what are certainly the earliest pennies of Henry II., are among the worst of the English coins in point of mintage. The barons of this reign are reputed by our historians to have struck coins; but only two or three such are known, and those of persons related to the king. Pennies are extant ascribed to Robert earl of Gloucester, bastard son of Henry I.; to Henry bishop of Winchester, base brother of Stephen; and to Eustace, Stephen's son. They are all of great rarity, as is the coin which bears the full-length effigies of Stephen and Henry II. The coin of Robert however is by some ascribed to Robert duke of Normandy, the eldest son of the Conqueror. Henry II., according to Ruding, had but one type; but there seems every reason to believe that the pennies which usually go by the name of the first coinage of King Henry III. are in reality the last coinage of Henry II. at the time he reformed his money, A.D. 1180. Of Richard I. and John we have no English money; but pence, halfpence, and farthings are extant of John, all struck in Ireland. Those coins with a full face, bounded by the inner circle, have the inscription IOHANNES DOM. and were struck at the time his father made him lord of Ireland; those which give the face inclosed in a triangle, and IOHANNES REX, were coined after he ascended the throne. The farthing of this last coinage is extremely rare. Of John's coins, Dublin appears to have been the only place of mintage. Henry III.'s pennies (if those which we have considered as the latest pennies of Henry II. really do not belong to Henry III.) have usually the numerals added to his name, HENRICVS REX III. Some of his pennies have HENRICVS REX TERCI, and a few HENRICVS REX ANG. His coinage, if we may judge from the quantity of his pennies which still remain, must have been a very extensive one. Halfpence and farthings are spoken of in a record of this reign, but none have appeared. The pennies of Edward I., II., and III. are usually thus distinguished by our antiquaries: those which give the king's name EDW. are ascribed to Edward I.; those with EDWA., EDWAR., and EDWARD, to Edward II.; those with EDWARDVS to King Edward III. A few with EDW. are known certainly to belong to Edward I., particularly those which have a moneyer's name on the reverse, ROBERT DE HADELEIE, who is known from records to have been a moneyer in 1280. Both Henry III. and Edward I. struck pennies in Ireland, in the manner of John's later coins, representing the king's head within a triangle. Edward I. struck halfpence and farthings in his great coinage of 1279, which are not unfrequently met with in the cabinets of collectors, as well as halfpence and farthings with the Irish type, struck at Dublin and Waterford. It may be sufficient, as regards these small coins, to say that they continued in currency for several centuries. The last silver farthing is known to have been coined in the reign of Edward VI., but no specimen of it has been seen: the last silver halfpenny was struck under the Commonwealth. The penny has continued through every reign to the present. Our limits will not allow of further minute description. Among the rarest in the later part of the series may be reckoned the pennies of Edward VI., Mary, and Philip and Mary. From the reign of Edward I. to Henry VIII., we have pennies which bear the privy marks of the bishops of Durham; from Henry IV. to Henry VIII. we have coins struck in the archiepiscopal mint at York; and others of the see of Canterbury, from archbishop Bourchier to archbishop Cranmer. The first English pennies weigh 22½ grains troy. Towards the close of Edward III. the penny weighs 18 grains, and in the reign of Edward IV. it fell to 12, after previously sinking to 15. In Edward VI.'s time, 1651, the penny was reduced to 8 grains, and after the 43rd of Eliz. to $7\frac{23}{31}$ grains, at which weight it still continues. The penny affords the best rule for estimating the other silver coins.

According to Grafton, Henry III., in 1249, ordered groats to be stamped, but none such are mentioned in any record. There is a large piece however found occasionally in the cabinets of the curious, sometimes ascribed to Edward I., but whether his, or Edward II.'s, or Edward III.'s, is uncertain. It occurs of different weights, from 80 to 138 grains, and represents the king's head on its obverse, within a double tressure of four arches, with mullets and roses; inscribed EDWARDVS DI. GR. REX. ANGL. The reverse, besides a continuation of the king's titles in the outer circle, has CIVI. LONDONIA within an inner one. There can be little doubt but that it was a trial-piece. Groats and half-groats were not introduced for currency till the 25th Edward III., and continue at present, though not for circulation. A silver fourpenny piece for circulation, of a different type from the ordinary groat, has been issued for circulation by King William IV., A. D. 1836. The groat received its name from the French *gros*, a large piece. In the time of Henry VII. and Henry VIII. groats and half-groats were struck in the archiepiscopal mints of Canterbury and York. It was one of the charges against Wolsey, that he had put the cardinal's hat upon the king's money, as is seen upon his York groats and half-groats.

The testoon, or shilling, was first coined by Henry VII., in 1503. The appellation of testoon was from the *teste* or *tête*, the head of the king, upon it: that of shilling is of old but uncertain origin. Pinkerton says, that coins of that name had been struck at Hamburg in 1407. The scilling was a denomination of money in the Saxon times.

Henry VIII. struck some patterns for a silver crown; but the first crown for currency was struck by Edward VI., with the half-crown, sixpence, and threepence. Queen Elizabeth, in 1558, coined three-halfpenny, and in 1561 three-farthing pieces. Pinkerton says they were dropped in 1582, but there is a three-halfpenny piece in the cabinets of the British Museum, bearing the date of 1599. Charles I. struck twenty-shilling and ten-shilling pieces in silver, but they were of very limited currency.

From the 43rd Elizabeth, 1601, the denominations, weight, and fineness of English silver have remained the same. It is worthy of remark, that, during all his distresses, King Charles I. never debased his coin.

The gold coinage of England is next to the silver in point of antiquity. The gold current with us, till the 41st Henry III., was foreign. In that year, 1257, a manuscript chronicle, in the archives of the city of London, states that the king made a penny of the finest gold, which weighed two sterlings, and willed that it should be current for twenty-pence. Three specimens of it only are yet known to have reached us; and two out of the three are preserved in the British Museum. They are from different dies. This coin is engraved in Snelling's 'View of the Gold Coin,' in the last edition of Folkes's 'Tables,' and in Pinkerton's 'Essay on Medals.' It is from Edward III. that the series of English gold coin really commences, for no more occurs till 1344, when that prince struck florins. The half and quarter-florin were struck at the same time. The florin was then to go for six shillings, though now it would be intrinsically worth nineteen. This coin being inconvenient, as forming no aliquot part of larger ideal denominations, seems to have been withdrawn. None have yet been found, but a few quarter-florins are preserved in cabinets, and one half-florin is known. In consequence, in the same year, the noble was published, of 6*s*. 8*d*. value, forming half a mark, then the most general ideal form of money. The obverse represents the king standing in a vessel, asserting the dominion of the sea. The noble was also attended by its half and quarter. This coin, sometimes called the rose noble, together with its divisions, continued the only gold coin, till the angels of Edward IV., 1465, stamped with the angel Michael and the dragon, and the angelets or half-angels were substituted in their place. Henry V. is said to have diminished the noble, still making it go for its former value. Henry VI. restored it to its size, and caused it to pass for 10*s*., under the new name of ryal. The ryal of 10*s*. and the angel of 6*s*. 8*d*., with their divisions of half and quarter, then continued the sole gold coins till, in 1485, Henry VII. issued the double ryal, or sovereign, of 20*s*., accompanied by the double sovereign of 40*s*. Henry VIII., in 1527, added to the gold denominations the crown and half-crown, at their present value, and in the same year gave sovereigns of 22*s*. 6*d*., ryals of 11*s*. 3*d*., angels of 7*s*. 6*d*., and nobles at their old value of 6*s*. 8*d*. In 1546 he struck sovereigns of the former value of 20*s*., and half-sovereigns in proportion. Henry VIIIth's gold, like his silver coin, was in the latter part of his reign much debased. Edward VI. coined a treble sovereign; and under James I. the sovereign was called a unite. The former coins however continued, with a few variations, till Charles II. coined the guinea, so called from the Guinea gold, out of which it was first struck in 1663, when it was proclaimed to go for 20*s*., but by tacit and universal consent never went for less than 21*s*. Charles II. likewise issued half-guineas, double guineas, and five-guinea pieces, which his successors, till King George IV., continued. George I. and George III. issued quarter-guineas; and George III. pieces of seven shillings in 1797. In 1815 sovereigns and half-sovereigns, of 20*s*. and 10*s*. each, were again coined, and the guinea and half-guinea were gradually withdrawn from circulation.

With the exception of the styca, the copper coinage of England arose a thousand years later than its silver. Queen Elizabeth had a great aversion to copper money, although the necessities of her people for small change were obvious. She suffered a pattern to be struck as the PLEDGE. OF. A. HALF PENNY, and James I. and Charles I. actually issued farthing tokens also as pledges; but no authorized coinage of copper was struck till 1672, when halfpence and farthings of that metal were first made public money. In 1684 tin farthings were coined, with a stud of copper in the centre. Others, as well as halfpence of the same metal, were struck by James II., and William and Mary. In 1693 the tin was called in, and copper renewed. Pieces of a penny and twopence in copper were coined in the reign of George III. The latter did not answer their purpose, and were soon discontinued. The penny pieces remain in circulation.

Our space will allow us to say less than we could wish upon the money struck in France by English princes. Of Anglo-Gallic silver coins we have deniers of Eleanor, wife of Henry II., as duchess of Aquitaine, with deniers and half-deniers of Henry II., and pennies and half-pennies of Aquitaine, and pence of Poitou and Rouen of Richard I. Of John and Henry III. we know of no Anglo-French money; but there is a lion of billon of Edward I., coined during the lifetime of his father after he had received Gascony, and a plentiful series of silver and billon coins of Edward III., of Edward the Black Prince, of Richard II., Henry IV., V. and VI. The denominations of the silver were the hardi, double hardi, groat, half-groat, penny and half-penny. In this class also fall the Calais groats and half-groats of the sovereigns of England, from Edward III. to Henry VI., and the Tournay groats of Henry VIII. Edward III. was the first of the English princes who struck gold money in France; the denominations were guiennois, leopard, chaise, and mouton; to these Edward the Black Prince added the hardi of gold and the pavilion; and Henry V. salutes and half-salutes. Henry VI. coined salutes, angelots, and francs in gold. The equivocal specimen of silver coin, supposed to have been struck by Margaret of Burgundy for Perkin Warbeck, is usually classed with the Anglo-Gallic series.

In respect to numismatic writers, we can only enumerate a few of the most important upon the various series of coins. On the Greek and Roman series, the best works are Eckhel's 'Doctrina Numorum Veterum,' Rasche's 'Lexicon Universæ Rei Numariæ,' and Mionnet's 'Description de Medailles Antiques Grecques et Romaines:' the last work in 5 vols., 8vo., with 7 vols. of Supplement, Paris, 1806–35. For the Roman alone, the reader may consult A. Morel's 'Thesaurus Familiarum Romanarum,' 2 tom fol., Amsterdam, 1734; and his 'Thesaurus Numismatum Imperatorum,' 3 tom., Amsterdam, 1752. Another which brings the Roman series to the close of the empire, will be found in Banduri's 'Numismata Imperatorum Romanorum a Trajano Decio ad Palæologos Augustos,' 2 tom., Lut. Par., 1718, with Tanini's 'Supplement,' in 1 vol., fol., Rome, 1791. See also Mionnet's work, in 2 vols., 'De la Rareté et du Prix des Medailles Romaines,' 8vo., Paris, 1827 The prices of the different coins, fixed according to their rarity, in this work are now the guide to the coin-dealers and collectors throughout Europe. To the English reader, Captain W. H. Smyth's 'Descriptive Catalogue of a Cabinet of Roman Imperial Large Brass Medals,' 4to., Bedford, 1834; and Akerman's 'Descriptive Catalogue of Rare and Unedited Roman Coins,' 2 vols., 8vo., London, 1834, will be especially useful. Pinkerton's 'Essay on Medals,' 2 vols., 8vo., 1789, with all its errors, is valuable as a general elementary treatise.

Bayer's work, 'De Numis Hebræo-Samaritanis,' 4to., 1781; and his 'Numorum Hebræo-Samaritanorum Vindiciæ,' 4to., 1790, are valuable works upon the Jewish coins.

On English coins, the best works are Leake's 'Historical Account of English Money,' 8vo., London, 1745; Snelling's various works; Folkes's 'Tables of English Coins,' as published by the Society of Antiquaries; and Ruding's 'Annals of the Coinage of Britain.' Simon has written an 'Essay towards an Historical Account of Irish Coins;' and Cardonnel his 'Numismata Scotiæ, or a Series of the Scottish Coinage.' On Anglo-Gallic coins, we have a quarto volume by Ducarel; a volume of similar size, 'A Description of the Anglo-Gallic Coins in the British Museum;' and 'Illustrations of the Anglo-French Coinage,' by Major-Gen. Ainslie, 4to., London, 1830; the last, and a very valuable publication.

On the French coinage, we have the works of Bouteroue and Le Clerc; on the Papal coins, Floravante. Argelati and Zanetti have written on the coins of Italy; and Florez on those of Spain. For the coins of Germany, the reader may consult Madai's 'Thaler-Cabinet,' 4 tom., Königsberg, 1765-8; and Weise's 'Gulden-Cabinet,' 2 tom., Nurnberg, 1780-2. For Danish coins, the 'Danske Mynter og Medailler,' 3 tom., fol., Copenh., 1791-4. On Bulgarian coins Fraehn's work, 4to., Casan, 1816. For Oriental coins, Marsden's 'Numismata Orientalia Illustrata,' 2 vols., 4to., London, 1823-5.

COINING. [MINT.]

COINING. The numerous and complicated laws upon this subject, passed from time to time during several centuries, as occasion called for penal enactments to protect the coin of the realm, were repealed by the recent stat. 2 Will. IV. c. 34. The making or coining of money being one of the exclusive prerogatives of the crown, the counterfeiting of the king's coin was in early periods of the history of English law considered to be a usurpation upon the royal authority, and upon that principle constituted the offence of high treason both by the common law and by various statutes. By the late stat., 2 Will. IV., c. 34, s. 3, it is enacted, with respect to gold and silver coin, That any person falsely making or counterfeiting any coin resembling, or apparently intended to resemble or pass for, the king's current gold or silver coin, shall be liable to transportation for life, or any term not less than seven years, or to imprisonment for any term not exceeding four years. The 4th section of the act imposes the same punishment upon the offences of colouring, washing, or casing over any metal or counterfeit coin so as to pass for the genuine gold and silver coin of the realm; and of filing, washing, or otherwise altering silver coin so as to pass for gold, or copper coin so as to pass for silver or gold. By the 5th section, persons impairing, diminishing, or lightening the king's current gold or silver coin, with intent to make it pass for the king's current gold and silver coin, are made liable to transportation for fourteen years, or imprisonment for three years.

By the 6th section of the statute it is enacted, That if any person shall buy, sell, receive, pay or put off, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, or offer so to do, at or for a lower rate or value than the same by its denomination imports; or if any person shall import into the United Kingdom, from beyond the seas, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, he shall be liable to be transported for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years.

By the 7th section it is enacted, That if any person shall tender, utter, or put off any false or counterfeit coin, resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, he shall be liable to imprisonment for any term not exceeding one year; and if any person shall tender, utter, or put off any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, and such person shall, at the time of such tendering, uttering, or putting off, have in his possession, besides the false or counterfeit coin so tendered, uttered, or put off, one or more piece or pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, or shall, either on the day of such tendering, uttering, or putting off, or within the space of ten days then next ensuing, tender, utter, or put off any more or other false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, he shall be liable to imprisonment for any term not exceeding two years. And it is further declared by the same section, that if any person who shall have been convicted of any of the offences thereinbefore mentioned, shall afterwards commit any of such offences, he shall be liable to be transported for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years.

The 8th section of the statute enacts, That if any person shall have in his custody or possession three or more pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, and with intent to utter or put off the same, he shall be liable to be imprisoned for any term not exceeding three years; and if any person so convicted shall afterwards commit the like misdemeanor, or crime and offence, he shall be liable to be transported for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years.

The provisions above abstracted relate to the protection of the gold and silver coin: by the 12th section of the same statute the following provisions have been made with respect to copper coin. It is by that section declared, that if any person shall falsely make or counterfeit any coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin; or if any person shall knowingly, and without lawful authority (the proof of which authority shall lie on the party accused), have in his custody or possession any instrument, tool, or engine adapted and intended for the counterfeiting any of the king's current copper coin; or if any person shall buy, sell, receive, pay, or put off, or offer to buy, sell, receive, pay, or put off, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, at or for a lower rate or value than the same by its denomination imports; every such offender shall be liable to be transported for any term not exceeding seven years, or to be imprisoned for any term not exceeding two years; and if any person shall tender, utter, or put off any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, knowing the same to be false or counterfeit, or shall have in his custody or possession three or more pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, knowing the same to be false or counterfeit, and with intent to utter or put off the same, every such offender shall be liable to be imprisoned for any term not exceeding two years.

The 10th section of the act contains the following provision against making, mending, or having in possession any coining tools. It enacts, that if any person shall knowingly, and without lawful authority (the proof of which authority shall lie on the party accused), make or mend, or begin to proceed to make or mend, or buy or sell, or shall knowingly and without lawful excuse (the proof of which excuse shall lie on the party accused) have in his custody or possession any puncheon, counter-puncheon, matrix, stamp, die, pattern, or mould, in or upon which there shall be made or impressed, or which will make or impress, or which shall be intended to make or impress, the figure, stamp, or apparent resemblance of both or either of the sides of any of the king's current gold or silver coin, or any part or parts of both or either of such sides; or if any person shall, without lawful authority (the proof whereof shall lie on the party accused), make or mend, or begin or proceed to make or mend, or buy or sell, or shall, without lawful excuse (the proof whereof shall lie on the party accused), have in his custody or possession any edger, edging tool, collar, instrument, or engine, adapted and intended for the marking of coin round the edges with letters, grainings, or other marks or figures apparently resembling those on the edges of any of the king's current gold or silver coin, such person knowing the same to be so adapted and intended as aforesaid; or if any person shall, without lawful authority, to be proved as aforesaid, make or mend, or begin or proceed to make or mend, or buy or sell, or shall without lawful excuse, to be proved as aforesaid, have in his custody or possession any press for coining, or any cutting engine for cutting by force of a screw, or of any other contrivance, round blanks out of gold, silver, or other metal, such person knowing such press to be a press for coinage, or knowing such engine to have been used, or to be intended to be used, for the counterfeiting of any of the king's current gold or silver coin, every such offender shall be liable to be transported beyond the seas for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years.

COIRE. [Grisons.]

COKE, EDWARD,[*] was born at Mileham, in the county of Norfolk, on the 1st of February, 1551-2. He was the only son of Robert Coke of Mileham, and Winifred, daughter and one of the heirs of William Knightley, of Morgrave-Knightley, in the same county. His father, who was a bencher of Lincoln's Inn, died in the year 1561, when Edward Coke was ten years old. Before that event he had been sent to the Free Grammar School at Norwich, whence, in September, 1567, he removed to Cambridge, and was admitted as a fellow commoner at Trinity College. After having spent three years at the University he went to London to commence his legal education. According to the practice of that time, he took the first step of his legal course by becoming a member of Clifford's Inn, a house of Chancery, or inferior inn, dependent upon the Inner Temple, and was admitted into the latter society April 24, 1572. On the 20th of April, 1578, he was called to the bar. During the continuance of his studies in the Inner Temple, he is said to have greatly distinguished himself in the exercises called Mootings and Readings, which constituted a necessary part of the education of an advocate in former times, and which excited a great degree of interest and emulation among the members of the societies called Inns of Court and Chancery.

In the course of the year after his call to the bar, the society of the Inner Temple appointed him reader at Lyon's Inn; and the intelligence and learning displayed by him, in the conduct of the exercises at which he presided in this capacity, raised for him a high reputation as a lawyer, and opened the way to that extensive practice at the bar, which he acquired with a degree of rapidity almost without a parallel in the history of the profession. Lloyd, in his 'State Worthies,' says that 'his learned lecture so spread forth his fame that crowds of clients sued to him for his counsel.' In the next term after he was called to the bar he argued a case of much nicety and importance, known to lawyers by the name of Lord Cromwell's Case, which he says, in his own report of it (4 Rep. 146), 'was the first cause that he moved in the King's Bench.' About three years afterwards he was associated with Popham, the solicitor-general, in arguing before the chancellor and the twelve judges in the case of Edward Shelley, where the important rule in the law of real property, which has since become celebrated as the 'Rule in Shelley's Case,' was laid down so distinctly that it has taken its name from this case, though the rule itself is of much higher antiquity. From that period until he became solicitor-general, his practice was enormous: it appears from the reports of that time that there was scarcely a single motion or argument before the court of King's Bench in which he was not engaged. Professional honours were the consequence of this large business in the courts; in 1586 he was chosen recorder of Norwich, and for years afterwards was called to the bench of the Inner Temple. In January, 1591-2, the corporation of London having with much difficulty and at the expense of an annuity of 100*l.* procured the resignation of Serjeant Fleetwood, unanimously elected Coke their recorder; but he resigned that office in June, 1592, on being appointed solicitor-general. In the same summer he became reader of the Inner Temple, and had delivered several readings on the Statute of Uses to a large audience, consisting of not less than 160 members of the society, when the appearance of the plague compelled him to leave London abruptly for his house at Huntingfield in Suffolk. Such was the honour and respect in which he was held by the profession, that on this occasion, as he records in his Notes, he was accompanied on his journey as far as Romford by a procession composed of nine benchers and forty other members of the Inner Temple. In March, 1594, he was appointed attorney-general, and as the office of solicitor continued vacant until the close of the following year, the duties and labours of both offices during that interval devolved upon him.

At this period originated the animosity between Coke and Bacon, which prevailed with little intermission during the life of the latter. As soon as the office of attorney-general became vacant, upon the removal of Sir Thomas Egerton to the seals, the earl of Essex used his most strenuous efforts to induce the queen to bestow that place upon Bacon, instead of promoting Sir Edward Coke from the inferior office of solicitor-general. The letters of Bacon to Essex and others, with relation to this intrigue, abound with sarcastic and contemptuous expressions respecting Coke, whose high reputation and great experience pointed him out as at all events a fitter man for the office than his rival, whose practice at the bar was never extensive, and who was then scarcely known in the courts.[*]

The state services imposed upon the attorney-general at the end of Elizabeth's reign were extremely laborious. The severity of the laws recently introduced against Roman Catholics had occasioned a succession of plots by foreign adventurers against the person of the queen, the investigation of which was necessarily committed to the attorney-general. The treasons of Lopez, of Patrick Cullen, of Williams and Yorke, and numerous others of inferior moment, occurred about this period: and the business of constant examination at the Tower, added to his Star Chamber duties and his undiminished practice in the common-law courts, must have imposed a weight of labour and responsibility upon Coke which no mind of common activity and energy could have undergone. Whole volumes of examinations in these cases, taken by himself and written with his own hand, which are still preserved at the State Paper Office, sufficiently attest his zeal and assiduity in the service. In February, 1593, Coke, being at that time solicitor-general, was elected a member of parliament for his native county of Norfolk. In his own memorandum of this circumstance he says, that the election was 'unanimous, free, and spontaneous, without any canvassing or solicitation on his part.' At the meeting of this parliament he was chosen speaker of the House of Commons.

---

[*] Many of the dates and incidents in this sketch of Sir E. Coke's life are taken from some characteristic memoranda in his own hand-writing prefixed to a volume of Notes among the Harleian MSS. in the British Museum. No. 6 87 This was probably the book which Lloyd mentions in his 'State Worthies' as 'a manual which Coke called *vade mecum*, from whence at one view he took a prospect of his past life, having noted therein most remarkables.' Roger Coke, in his 'Detection of the Reign of King Charles,' says, that when Sir E. Coke was on his deathbed, a king's messenger seized all his books and papers, and among them his 'Comment on Littleton, and the History of his Life before it, written with his own hand.' These notices seem to describe the identical book which has now found its way into the British Museum. It is remarkable that these notes have not been referred to by any of Coke's numerous biographers.

[*] Bacon, in a letter to Lord Burleigh, alludes to the objection made by the queen to his appointment, on the ground that he was 'rather a man of study than of practice and experience.' (*Cabala*, p. 17.)

In the year 1582 Coke married the daughter and heiress of John Paston, Esq., of Huntingfield, in Suffolk, through whom he became connected with several families of great opulence and importance, and with whom he received a fortune of 30,000*l.* By this lady he had ten children. She died in June, 1598. In the month of November in the same year Coke contracted a second marriage with the widow of Sir William Hatton, daughter of Thomas Lord Burleigh, and grand-daughter of the lord high treasurer, which, though an advantageous alliance in point of connection and property, was by no means a source of domestic happiness. The marriage itself involved all the parties concerned in it in considerable embarrassment: for having taken place without licence or banns, Coke and his lady, together with the clergyman, Lord Burleigh, and all who were present at the ceremony, were cited to appear in the Archbishop's Court; and it was only in consequence of their making a full submission, and pleading their ignorance of the law (a singular excuse in Coke's mouth), that they escaped the sentence and penalties of excommunication.

Sir Edward Coke held the office of attorney-general until the death of Queen Elizabeth; and having always been favourable to the title of James I., cooperated cordially with Cecil and the other members of the late queen's council in making the necessary arrangements for the peaceable accession of the king of Scotland to the crown. James, upon his arrival in London, received him into his full confidence and favour, and continued him in his office of attorney-general.

Coke's sound judgment and extensive legal knowledge, united with his fervent attachment to Protestantism, rendered him a valuable officer of the crown in the various proceedings against the Roman Catholics at the close of Elizabeth's reign, and the beginning of that of James I. In the examinations respecting the several assassination-treasons, which have been already mentioned, as well as that of Squire in 1598, of the Raleigh conspiracy in 1603, of the Gunpowder Plot in 1605, and of numerous other treasonable and seditious movements imputed to the Catholics during the period that he filled the office of attorney-general, he engaged with a zeal and ardour far beyond mere professional excitement; and the temper displayed in his speeches and general conduct on the several trials is much more that of a religious partisan than of a legal advocate. It is common with Catholic writers to attribute to him the utmost barbarity in the use of the rack and the general treatment of prisoners under examination. That he, who in his writings forcibly condemns the use of torture, was nevertheless in his official character the constant instrument of the crown for applying this odious process, is beyond all question: but it must be remembered that what he wrote on this subject was written long after the period of which we are now speaking, in the dawn of a better order of things; and that the use of the rack for discovering state secrets was common throughout Europe in his time, and had been in daily practice in England for centuries before he was born. There is no satisfactory proof that he was coarse and cruel in his conduct towards prisoners under examination, and on the contrary, Father Cornelius, the Jesuit, who was repeatedly examined by Coke, said he found him 'omnium hominum humanissimus;' and Garnet, in his intercepted correspondence, and also on his trial, admits that he was constantly treated by him with courtesy and kindness.

There is no doubt however that as the advocate of the crown on trials for state offences, he displayed a degree of intemperance and asperity not only shocking to the feelings of readers familiar only with the more civilized character of criminal proceedings at the present day, but strongly offensive even to contemporaries.

With the trials of the conspirators in the Gunpowder Plot in 1606, the career of Sir Edward Coke as an advocate closed. In the month of June in that year he received his appointment as chief justice of the Common Pleas. He retained the situation upwards of seven years; and in the discharge of the common judicial duties at this period, his profound learning and unwearied industry procured him the highest reputation. At this time too, though he has sometimes been reproached for a haughty and unconciliating deportment on the bench, the bitterness of temper which he had displayed at the bar appears to have been suppressed or softened; and in several constitutional questions of the highest importance which occurred while he was chief justice of the Common Pleas, and in which he resolutely opposed the views of the king, especially in the conflicts between the ecclesiastical jurisdictions and the courts of common law, and in his resistance to the encroachment of prerogative on the subject of royal proclamations, he displayed great integrity and independence. With a view to corrupt his uncompromising disposition, his crafty rival, Bacon, who was then solicitor-general, suggested his promotion to the chief-justiceship of the King's Bench; and accordingly he received his patent for that office in October, 1613, and a few days afterwards, in consequence of a special order from the king, took his seat at the board as a privy councillor. In the following year he was elected high steward of the University of Cambridge.

The project of making the chief justice 'turn obsequious' by his advancement, which was no doubt entertained by the court, and was expressly avowed by Bacon, altogether failed. In the case of Peacham, who was prosecuted for treason in the year 1615, for having in his possession a sermon supposed to contain sedition, written by him, but never preached or published, Coke, after long hesitation to deliver what he quaintly called an 'auricular opinion,' seems at last to have declared that the offence was not treason. His exertions in the prosecution of the murderers of Sir Thomas Overbury in the same year, though praised by Bacon in conducting the case as attorney-general, gave displeasure to the king; and his independent conduct in the case of Commendams, which occurred in 1616, finally determined the court to remove him from his office. The transaction was this. A serjeant-at-law, in the discharge of his duty as an advocate in the Court of Common Pleas, was supposed to have used matter in his argument which tended to question the royal prerogative; upon this the king required the judges to proceed no further in the case without his warrant. The twelve judges conferred upon this message, and resolved that in a common dispute between party and party it was their duty to proceed notwithstanding the king's mandate. Upon this they were summoned to the council table, and personally reprimanded by the king; and all of them, excepting the lord chief justice, acknowledged their error, and craved pardon for their offence upon their knees. Sir Edward Coke, on the contrary, after craving pardon for any formal errors which he might have committed, boldly justified his opinion upon the substantial point, contending that the king's command for staying the proceedings was a delay of justice, and consequently against the law, and contrary to the judges' oath. After much discussion, the lords of the council proposed the following question to the judges:—'Whether in a case where the king believed his prerogative or interest concerned, and required the judges to attend him for advice, they ought not to stay proceedings till his Majesty had consulted them?' All the judges at once answered in the affirmative, except Lord Coke, who only said 'that, when the case happened, he would do that which should become an honest and just judge.'

The court now despaired of bending the stubborn integrity of the chief justice, and determined at all events to displace him. Accordingly, on the 26th June, 1616, as a preliminary to his removal, he was summoned before the council, and charged with several frivolous accusations, some of them founded upon alleged malversations while he was attorney-general, to all of which he returned distinct answers. Four days afterwards, he was again summoned to appear before the council; upon which occasion he was reprimanded, sequestered from the council-table during the king's pleasure, enjoined not to ride the summer circuit as judge of assize, and ordered to employ his leisure in revising many 'extravagant and exorbitant opinions' set down in his Book of Reports. In the course of the vacation he was again summoned before the council to answer a list of twenty-eight objections to doctrines contained in his Reports, which a contemporary writer observes, 'were either so weak in themselves, or so well answered, that they were readily reduced to five.' (Chamberlain's *Letter to Sir D. Carleton*, 26th Oct., 1616.) In November, 1616, he received his writ of discharge from the office of chief justice: and was succeeded by Sir Henry Montague, who was expressly warned by the lord-chancellor Egerton 'to avoid the faults of his predecessor, who had been removed for his excessive popularity.'

From causes not very distinctly explained in the letters and histories of the day, which probably were connected with an intrigue for the marriage of his daughter to Sir John Villiers, afterwards Viscount Purbeck, Sir Edward Coke, though he never afterwards filled a judicial situation, was, at no long interval, restored to a certain degree of royal favour. In September, 1617, he was reinstated as a member of the privy council, and in July, 1618, he was appointed a 'commissioner for the exercising the office of lord high treasurer of England,' jointly with archbishop Abbott, lord-chancellor Bacon, and several others. (See Devon's *Pell Records*, temp. Jac. I.) In the course of the next three years he was employed in several other commissions of a public nature, and until the year 1620 he was constant in his attendance at the board. In the parliament which assembled in that year he was returned as a member for the borough of Liskeard in Cornwall. In this parliament he distinguished himself as one of the most able and zealous advocates of the liberal measures which were proposed; he became a strenuous opponent of the pernicious monopolies by which at that period the freedom of trade was fettered, and took an animated part in that struggle between the prerogative pretensions of James and the freedom of debate, which ended in the celebrated resolution of the Commons, 'that the liberties, franchises, privileges, and jurisdictions of parliament are the antient and undoubted birth-right and inheritance of the subjects of England.' During the year 1621, he attended only three times at the privy council; and on one of those occasions, namely on the 5th Oct., 1621, he seems to have appeared only to inform the board that he had induced one Johnstone to give up a grant which he had obtained from the king, as 'both a grievance to the subject, and a disservice to the state;' which information he desired might be recorded in the council register. (*Council Books.*) His adherence to the popular or *country* party gave great offence to the court, and he was accused of various offences and malpractices. The king, at this period, was so incensed against him, that before he would grant his warrant for a general pardon, at the end of 1621, he expressly commanded the privy council to consult upon the means of excepting Sir Edward Coke from the benefit of it; and on the 27th of December of that year, Coke was arrested and committed to the Tower, where he remained a close prisoner until the 6th of August, 1622. While he was in the Tower, proceedings were instituted against him both in the star-chamber and the court of wards, the precise nature and issue of which cannot now be ascertained. Upon his enlargement from the Tower, he was ordered to confine himself to his house at Stoke Pogis, and not to repair to the court without express licence from the king. After his disgrace on this occasion, he was never again restored to the council-board. At the end of 1623 he was appointed a commissioner, together with Sir William Jones, one of the judges of the Common Pleas, and two other persons, to inquire into the church establishment in Ireland. That he was on the point of going on this mission appears from the fact that a passport dated 16th January, 1623-4, was actually granted by the council. Some accident however prevented his departure.

In the first parliament of Charles I., called in April, 1625, Sir E. Coke was again returned as one of the knights of the shire for the county of Norfolk, as he says in his Note, 'sine aliquâ motione aut petitione inde a me prœbitis.' At the commencement of this parliament he adopted a moderate tone. He dissuaded the house from insisting upon grievances, and urged conciliatory measures; saying, that 'as it was the very beginning of the new king's reign, there could be no grievances as yet.' But this disposition to peace was overcome by the determined tendency of the crown to arbitrary measures; and the king being unable to obtain any answer to his demand of a subsidy, but repeated remonstrances against grievances, abruptly dissolved the parliament. He was compelled, however, by his pecuniary wants, to assemble a new parliament in the course of the same year, having previously appointed Sir Edward Coke and three other popular leaders sheriffs of counties, in order to prevent their serving as members. Coke, having been in this manner named Sheriff of Buckinghamshire, was again returned as knight of the shire for Norfolk; and though in consequence of his shrievalty, he did not take his seat in that parliament, no new writ was issued to supply his place, and it was considered that he was *de facto* a member of the house. He mentions this circumstance in his 'Fourth Institute,' p. 48, though he does not state it to have been his own case; and says, that 'having a subpœna out of chancery served upon him, he had his privilege of parliament allowed unto him by the judgment of the whole House of Commons.' On occasion of the third parliament summoned by Charles I. in March, 1628, Sir Edward Coke was returned for two counties, Buckingham and Suffolk; but he tells us that 'he chose the former, because he resided there, and because his election for that county took place first.' In this parliament, though now in his 79th year, this extraordinary man asserted and defended the constitutional rights of the people of England with all the energy of youth, and all the sagacity of age. By his advice, and with his active cooperation and assistance, which his extensive and varied experience rendered particularly valuable, the celebrated Bill of Rights was framed; and by his perseverance and reasoning the lords were, after many conferences, induced to concur in the measure, which was, at last, and after many ineffectual attempts at evasion, reluctantly assented to by the king. One of the last acts of his public life was his spirited denunciation of the Duke of Buckingham as the cause of all the misfortunes of the country. As a proof of the earnest feelings by which he was impressed, Rushworth records that, on this occasion, 'Sir Edward Coke, overcome with passion, seeing the desolation likely to ensue, was forced to sit down when he began to speak, through the abundance of tears.' At the close of the session of parliament in March 1629, the growing infirmities of advanced age induced him to withdraw from public life, and to spend the remainder of his days in retirement on his estate at Stoke Pogis, in Buckinghamshire. Still it appears that his vigorous and active mind was not without employment; and the last years of his life are said to have been occupied by the revision of the numerous works which he left behind him.

The last entry in his note-book, written with almost as firm a hand as he wrote at the age of 40, records the following incident, which may possibly have been the cause of his death:—

'Memorandum. Die Jovis, the iii^rd^ of May, 1632, riding in the morning in Stoke, between eight and nine of the clocke to take the ayre, my horse under me had a strange stumble backward, and fell upon me (being above 80 years old), where my head lighted nere to sharpe stubbes, and the heavy horse upon me. And yet, by the providence of Almighty God, though I was in the greatest danger, yet I had not the least hurt,—nay, no hurt at all. For Almighty God saith by his prophet David, "The angel of the Lord tarrieth round about them that feare him, and delivereth them." Et nomen Domini benedictum, for it was his work!'

He died on the 3rd of September, in the following year, repeating with his last breath the words, 'Thy kingdom come, thy will be done;' and was buried in the family burying-place of the Coke family in the church of Titeshall, in Norfolk.

The most celebrated of Sir Edward Coke's works is the treatise commonly known by the name of 'Coke upon Littleton, or the First Institute.' It consists of a minute and laborious commentary upon the text of Littleton's 'Tenures,' in the course of which almost the whole learning of the common law, as it existed in his time, is digested and explained. This book has, ever since the time of Lord Coke to the present day, been considered as a work of the highest authority in the municipal and constitutional law of England. The 'Second Institute' contains notes on several antient statutes; the 'Third Institute' is a treatise on criminal law; and the 'Fourth Institute' treats of the origin and jurisdiction of different courts. Besides these works, Sir Edward Coke was the author of a treatise on copyholds, entitled 'The Complete Copyholder,' and a 'Reading on Fines.' He also published a collection of Reports, which are still of great value to the profession; and at the time of their appearance formed an epoch in the history of the law. Sir Francis Bacon speaks of this produce of the industry and learning of his great rival in terms of high and deserved commendation; and justly ascribes to the Reports the praise of having preserved the vessel of the common law in a steady and consistent course; 'For the law,' says he, 'by this time had been like a ship without ballast, for that the cases of modern experience are fled from those that are adjudged and ruled in former time.'

COL, COLLE, from the Latin *collis*, 'a hill or ascent,' is a name given in Italian, and in the dialects of the Italian and Romanæ languages, to several mountains in the Alps and Apennines over which there is a road or pass. The name is applied both to the pass itself, and to the mountain. The principal Cols are the Col de la Seigne and Col de Bonhomme, in the Pennine Alps south of Mont Blanc; the Col de Balme and Col Ferret in the same chain north of Mont Blanc, the latter adjoining the St. Bernard; the Col d'Argentiere in the Maritime Alps south of Mount Viso, and over which is a pass for mules leading from the valley of Barcelonette in France into the valley of the Stura in Piedmont. A branch of the antient Via Æmilia led over this pass, which is one of the most direct from France into Piedmont, and has been repeatedly used by the French in their invasions of Italy. The Col di Tende lies between Piedmont and the county of Nice, on the road from Turin to the latter town, which is the only carriage-road over the Maritime Alps. [ALPS.] The term Col implies a depression in the mountain, however high, which affords a natural pass; for instance, in the great ridge adjoining Mont Blanc, which divides the valley of Chamouny from that of Aosta, there is a lofty needle or summit, called Le Géant, 'the Giant,' which is above 13,000 feet high. By the side of this great pyramid, and between it and Mont Blanc, there is a considerable depression, called Le Col du Géant, which affords in summer a practicable, though dangerous communication between Chamouny and Cormayeur in the Val d'Aosta. The highest part of the Col du Géant is about 10,000 feet. This pass was first tried in the last century by a guide of Chamouny, called Michel Cachat, who ever after was called Le Géant; it was afterwards passed by Saussure, Bourrit, and others.

There are several passes in the Apennines called by the name of Col: one of the most known is Col Fiorito, on the road from Rome to Loreto and Ancona. There are also several towns in Italy, especially in Tuscany, called Colle, from being built on some hill.

In Catalonia also, where a dialect of the Romanæ language is spoken, the appellation of Col is applied to mountain-passes, such as Col de Creu, near Vich, and Col de Balaguer, near the town of that name.

COLAPORE, a small independent Mahratta state, situated within the province of Bejapore, in the region of the Western Ghaut mountains, being partly below and partly within the Ghauts. The territory of the Colapore rajah is so intermixed with that of the British and of other Mahratta chiefs, that it would be difficult to describe its boundaries. [BEJAPORE.] The state of Colapore was founded by Sumbajee, the grandson of Sevajee. In 1728 Sumbajee was confederated with the Nizam, and accompanied his army to Poona; and in 1731 a treaty was concluded between the Peishwa and Sumbajee, by which it was agreed that the lands of the province lying north of the Kistna should belong to the Peishwa, that all between the Kistna and Warna and the Toombuddra should belong to Sumbajee, and that all conquests south of the Toombuddra should be divided equally between them. The territory thus assigned to the rajah of Colapore was then partly in the actual possession of the Moguls, and partly of other chiefs, called Dessyes, who had set up for themselves. It was not until the subsequent reign of Madhoo Rao, about the year 1762, that the whole was effectually brought under the rajah's power. The Colapore territory became after this the constant scene of war and turbulence, and a place of refuge for all the plunderers and pirates of neighbouring countries. In 1804 the rajah was at war with the Peishwa, and after a long struggle, in which the latter succeeded in capturing the chief places in the state, and in reducing the rajah's government nearly to the point of extinction, the British government interfered for the establishment of peace, and procured the restitution of his towns. This occurred in 1812, after which the state of Colapore enjoyed a long continuance of tranquillity from without. In 1821 the rajah was privately assassinated in his palace, and was succeeded by a son of immature age, during whose long minority the country fell into a state of great disorder; the strong holds in the Ghauts were held by petty chiefs, who rebelled against the superior authority of the rajah, and the state of disorganization became such as to call for a report to the English government from the political agent in the Deccan, in which it was stated that 'robberies and other outrages are frequent in all parts of the Colapore country; and when one occurs, no person ever seems to be near the spot whose business it is to prevent the offence, or to secure the offender. After many delays a case of robbery sometimes finds its way to the rajah's ears, and if he happens to be struck with its enormity, he orders out the Tuppasnuves with a body of horse and foot to hunt the perpetrators. The party after scouring the country, and probably becoming as great a nuisance as the thieves themselves, return to Colapore, and report that it arrived too late to trace them. Under such misrule the potails, who should be here what the justices of the peace are in England, become the abettors of rogues instead of their terror, and the officers of police become thieves instead of thief-takers.' The young rajah on taking the government into his own hands proved to be of an arbitrary disposition, and early lost the good esteem of his subjects by his exactions and his degrading vices. In 1825, 1826, and 1827, the rajah having committed aggressions in the territories of some Mahratta Jagheerdars under the protection of the English, his territory was occupied by our troops, and the powers of government were temporarily placed in the hands of a minister appointed by the governor of Bombay. In each of the years just mentioned a treaty was concluded with the rajah, by which he bound himself to desist from acts of aggression; but these treaties having been forced upon him, their provisions were broken upon every occasion that presented itself, and in 1829 a definitive treaty restricted him from keeping up a greater force than 400 horse and 800 foot soldiers: some districts in which he had committed oppressions against the Zamindars were at this time taken from him; British garrisons were placed in the capital and in the fortress of Punalaghur at the rajah's expense, and a chief minister for the future management of his government was to be permanently appointed by, and removable solely at the pleasure of the English government.

(*Selection of unpublished papers, from the records of the East India House; Report of Committee of House of Commons on the Affairs of India*, 1832—*political section*).

COLAPORE, the capital of the state just described, is situated in 16° 19′ N. lat. and 74° 25′ E. long., in a valley between a curved range of hills, by which it is protected on three sides, the fourth side being protected by two hill-forts about ten miles north-west from the town. These forts stand upon rocks which are about 300 feet above the level of the valley, and which present natural perpendicular ramparts of basalt, from thirty to sixty feet high. The two forts are connected together; one of them, called Penowlghur, covers a space three and a half miles in circumference, in which area are several dwellings, lofty trees, gardens, and fine tanks. The works immediately connected with the town of Colapore are not strong. The town is 120 miles south of Poona.

COLAPTES. [PICIDÆ.]

CO'LARIS. [EURYSTOMIDÆ.]

COLBERG, a town and strong fortress in the administrative circle of Cöslin, in the Prussian province of Pomerania, about 170 miles north-east of Berlin, and in 54° 9′ N. lat., 15° 34′ E. long. It is on the right bank of the Persante, which empties itself into the Baltic about a mile below the town, and at its mouth forms a harbour, called the Münde; which properly consists of two dams, carried out from the banks of the river into the sea, and protected by redoubts. Colberg contains 720 houses and 5900 inhabitants, five Lutheran churches, five hospitals, a workhouse, a house of correction, an exchange, a foundation in a nunnery for seven daughters of noble families, and nine of citizens; an orphan asylum, a gymnasium, &c. Colberg has a salmon, haddock, and lamprey fishery; manufactures of woollens, anchors, and brandy; also salt-works, which however do not yield above 1620 tons annually. The absence of fresh-water springs is supplied by admirable but very expensive water-works: the water, which is raised by a wheel to the height of forty feet, is conveyed in pipes to every part of the town.

Colberg was formerly one of the Hanse towns, and till 1812 the seat of a collegiate chapter. The modern fortifications and outworks were commenced in 1773. It was taken after a siege of several weeks by Gustavus Adolphus, in 1630; was besieged by the Russians in 1758, 1760, and 1761, and surrendered to them by capitulation on the 16th December, in the last-mentioned year. The French invested it without success in 1817. It has a considerable trade, both inland and foreign, and a brisk woollen market. Its military strength is greatly increased by the swampy nature of the country around it.

COLBE'RT, JEAN BAPTISTE, born in 1619, at Rheims, was brought up to business. He was first employed at Lyon, in a commercial house, and afterwards went to Paris, where he was introduced, about 1648, to Mazarin. (Grosley's *Mémoires*.) Mazarin employed him first as an amanuensis, but afterwards made him intendant or steward of his vast fortune. He appointed him his executor on his death-bed in 1661, and recommended him to the king as a man deserving all his confidence. Louis XIV., on appointing Colbert contrôleur-général des finances, had many conferences with him, which led to the dismissal and imprisonment of Fouquet, the superintendent of the finances, who had assisted in dilapidating the resources of the state to serve the cupidity of Mazarin. On the trial there was a manifest anxiety on the part of the court and of Colbert to have Fouquet condemned to death, but D'Ormesson, one of the reporting judges, stood firm; he found much abuse and mal-administration, but no proof of peculation. Fouquet was condemned to banishment, and his property was confiscated. Louis XIV. aggravated this sentence into imprisonment for life in the citadel of Pignerol.

Colbert advised the king to form a chamber of justice for the liquidation of the debts of the state. The finances were in a ruinous condition; out of eighty-four millions which the people paid, the treasury received only thirty-two. The farmers of the revenue had in their hands all the resources of the kingdom; it was calculated that during the last five years they had appropriated to themselves eighty millions. They were now called to a severe account, and all the forms of inquisitorial process, torture not excluded, were employed to convict them. The result was that Colbert recovered for the king the sources of the public revenue, and reduced the debts of the state by an arbitrary composition, which was, in fact, a real bankruptcy. Having got rid of the burdens, he next applied himself to simplify and improve the collection of the revenue. He reduced by two-fifths the tailles, or land and income tax, which was unequally distributed, owing to the exemptions of the privileged classes. Finding this tax unmanageable, Colbert preferred reducing it, to make it weigh less heavily on the poorer classes. He founded his chief dependence on indirect taxation, or taxes upon consumption, which he raised not less than tenfold. Besides the octroi, or barrier duty on provisions, of which he appropriated one half to the treasury, and the aides or excise duties on wine and spirits, he imposed a stamp duty upon paper used in commercial and judicial proceedings, a stamp on plate, a duty on paper, a licence duty, and he established the monopoly of tobacco, &c. He also made a new and minute tariff for the custom duties. At his death, 1683, the regular revenue of France was 116 millions of livres, of which 23 were absorbed by the charges of collection and administration, and the rentes or annuities due by the state, leaving ninety-two millions of net receipt, instead of thirty-two, which he had found when he entered on office twenty-two years before. (Lemontey, *Pieces Justificatives*.) But one half only of this increase was obtained through additional taxation; the other half was the result of better order and economy. Colbert however had to deal with a sovereign, absolute, young, fond of pleasure, of pomp, and of war, seconded by an ambitious and unprincipled minister, Louvois. In the latter years of his administration Colbert was therefore obliged to have recourse to ruinous loans, an increase of the oppressive tailles, the sale of offices and honours, and other extraordinary or war expedients. This took place during the second war of Louis XIV., which began in 1672, and ended by the peace of Nimeguen, 1678-9. Colbert's aversion to loans was very great. He said to Lamoignon, who had supported in the council the proposal of a loan, 'You don't know the man we have to deal with (meaning the king). You have opened a sore which your grand-children will not be able to heal.'

Colbert's most strenuous and effective efforts were directed to the encouragement of commerce and manufactures. To accomplish his object, he adopted the only means known at that time, perhaps the only means practicable in his situation, and under such a government as that of Louis XIV., privileges, patents, monopolies, bounties, and honours. He is generally looked upon as the inventor, or at least the great propagator, of the system of the balance of trade. He made numerous regulations to protect, as it was then called, the various branches of national industry. He also forbade the exportation of corn with the view of insuring plenty, but the result was that cultivation declined, and France suffered several severe dearths under his administration. He is accused of having sacrificed agriculture to manufactures, but in fact his principles were erroneous with regard to both. One merchant, more enlightened than the rest, being consulted by him on the best means of favouring commerce, answered him, 'Laissez faire et laissez passer,' 'let us alone, leave us free and uncontrolled in our transactions, and let goods pass freely,'—advice which Colbert did not understand. In the subsequent century there rose in France another school, opposite to his, which saw in agriculture alone the real wealth of a state: these men were called 'economistes.' Mengotti, in his sensible treatise 'Il Colbertismo,' has explained the principles and exposed the errors of both. But whatever may be thought of Colbert's measures, he certainly succeeded in giving a great impulse to French industry; he roused and directed the national mind towards a new and useful exercise of its faculties: the history of French manufactures may be said to begin with Colbert. Woollens, silk, glass, pottery, leather, and iron manufactures, were either created by him, or greatly enlarged and improved. He founded Quebec and Cayenne, made new settlements in India and on the coast of Africa, and favoured the colonies of Martinique and St. Domingo. He chartered privileged companies for the East and West Indies. He turned his attention to internal communications, restored the old roads, constructed new ones, planned and effected the great canal of Languedoc, and projected another in Burgundy. He also established a free port at Marseille, sent consuls to the Levant, and thus secured to France a considerable part of that valuable trade. He bought Dunkerque, and Mardyk, on the coast of Flanders, from Charles II. of England, for the sum of five millions of livres (1662). He also founded the dock-yards of Brest, Toulon, and Rochefort. When he was made minister of marine, in 1669, in addition to the other departments he held, France had only a few old ships of war rotting in the harbours. Colbert purchased new ones abroad, constructed others at home, and in 1672 France had sixty ships of the line and forty frigates. But this creation of a navy was extended by the ambition of the king much beyond Colbert's original views, which were chiefly directed to the protection of the merchant trade.

Colbert brought the light of science into the various departments of the administration: his arrangement of the various offices, and the distribution of labour in each, have been highly extolled. He caused the first statistical tables of the population to be made out, and he collected the old charters and historical records of the kingdom. He removed the king's library from the miserable premises in the Rue de la Harpe, placed it in two houses near his own hotel, and increased it from 16,000 to 40,000 volumes. At the same time he formed his own extensive and valuable library, the MSS. of which alone amounted to 14,300 volumes, which his grandson afterwards sold to the king. He instituted a commission of legislation which framed the various ordonnances of civil and criminal process, of commerce, of the woods and forests, and of marine, published in 1670 and the following years, and which with all their imperfections constituted the first code of laws for France, and from which the various legislative commissions appointed by Napoleon drew most of their materials. [CODES, LES CINQ.] It was the first separation of the various branches of legislation, which had till then been confounded together in the ordonnances issued upon the spur of occasions. He also had a series of laws compiled concerning the negroes and their masters in the colonies, which was called '*le Code noir*.' A minister strict, orderly to minuteness, and averse to prodigality, could not well sympathize with Louis XIV. Colbert was ambitious, and strongly attached to his plans, which he conceived to be for the prosperity and glory of France. In order to captivate the king by means of one of his favourite tastes, that of building, which in some measure coincided with his own views, he purchased the office of superintendent of the public buildings in 1664. The gardens of the Tuileries, the Hôtel des Invalides, the façade of the Louvre, the triumphal arches of St. Denis and St. Martin, the Boulevards, and some of the quays along the Seine, were erected under him. He also began the structure of Versailles; but the king's passion for building, thus stimulated, went far beyond Colbert's intentions, and vast treasures were sunk in a gorgeous and useless work. Colbert instituted the Academy of Sciences, and those of Inscriptions and of Architecture. He reformed the Academy of Painting, and established the school at Rome for French artists. He transferred the Académie Française to the Louvre, and became one of its members. His temper was absolute, like that of his sovereign; he deprived Mézerai of his pension because he had written on the legality of taxation, and he laboured to lower the influence of the parliament of Paris. His manners were cold and repulsive; a poet of the time called him 'a man of marble.' Slow in conceiving his plans, and cautious in deciding upon their execution, he courted and listened to advice; but, when once resolved upon, his will knew no obstacles either of delicacy, feeling, or commiseration. A clear judgment, an iron will, and an indefatigable labour, supported him through his twenty-two years of administration. At last, seeing his rival Louvois enjoying the ascendency over the king's mind, Louis preparing himself for new wars, and maintaining the war-taxes which ought to have been repealed at the peace; grieved also at the incipient persecution of the Protestants, whose commercial and manufacturing industry Colbert fully appreciated, among whom he had chosen some of his best subalterns in the administration, and of whose services he was deprived by an edict which excluded the Protestants from financial appointments, Colbert felt all the pangs of disappointment for his ill-appreciated services. Exhausted with labour he fell ill, and shortly after died, 6th September, 1683, at sixty-four years of age. When near his death a letter from the king was brought to him, but he refused to open it. 'I will hear no more of him; he must leave me in peace now,' he said. 'Had I done for my God what I have done for that man, I should have been saved twenty times, while now I do not know where I am going to.' Father Bourdaloue attended his last moments. The people, enraged at the taxes, threatened to tear his body to pieces. He was buried in the night, attended by a military escort.

Colbert's first son was made Marquis of Seignelay, and another became Archbishop of Rheims. His brother held also high offices, and was made Marquis de Croissy. Colbert built himself a splendid mansion at Sceaux, and he left a fortune of ten millions of livres, the fruits of his rigid economy and of the liberality of Louis. (*Notice sur Jean Baptiste Colbert* in the *Œuvres de Lemontey*, vol. v., *Pièces Justificatives*, Paris, 1829; see also *Mémoires de Charles Perrault*, Colbert's secretary; and *Particularités sur les Ministres des Finances*, par Montyon. The several *Vies* and *Eloges* of Colbert are not worthy of much credit.)

COLCHESTER, a borough and market town, having separate jurisdiction, in the N.E. part of the county of Essex; locally situated in the hundred of Lexden, 22 miles N.E. by E. from Chelmsford, and 51 N.E. by E. from London. The liberties of Colchester, which are co-extensive with the borough, include the town of Colchester, and the parishes of Bere-church, Greenstead, Lexden, and St. Michael, Mile End, and comprise an area of 11,770 statute acres.

Colchester is generally supposed to be the Camalodunum of the Romans. There are few places in England where more Roman antiquities have been found: Morant mentions 'bushels' of coins of Claudius, Vespasian, Titus, Domitian, and their several successors. In addition to which, the town-walls, the castle, many of the churches, and other antient buildings, are chiefly built of the Roman brick. Numerous vases, urns, lamps, both bronze and in pottery, rings, bracelets, &c., as well as tessellated pavements, pateræ, and other Roman antiquities have at various times been dug up within the walls and in the neighbourhood.

By the Britons it was called Caer Colon, and finally by the Saxons Colne-Ceaster, from the Latin 'Castra,' and its situation on the river Colne. Colchester was strongly fortified by Edward the Elder, and although it had gradually diminished in importance as London increased, still at the time of the Norman survey it was a place of considerable note. In 1218 it was taken by Prince Louis, son of Philip II. of France, who had been invited into England by the rebellious barons to assist them against king John. In the reign of Edward III. the town contributed five ships and 170 marines towards the naval armament raised to blockade Calais.

Early in the civil wars the inhabitants of Colchester declared against the Royalists; and in 1648 the town sustained a memorable siege. Having been obliged to surrender to the royal forces, the city was garrisoned by Sir Charles Lucas and Lord Goring. Fairfax soon arrived, and summoned Lord Goring to surrender, and on his refusal, proceeded to storm the city; but after seven or eight hours' attack he ordered his troops to retire, and began the most rigorous blockade. The Royalists bravely held out for eleven weeks, but at last all the provisions of the place having been consumed, and the soldiers and inhabitants being compelled to live on horses, dogs, and other animals, the garrison was obliged to surrender at discretion. Sir Charles Lucas, Sir George Lisle, and Sir Bernard Gascoigne, were condemned to death. Gascoigne being a foreigner, his sentence was remitted, but the other two were shot a few paces from the castle walls. The town was fined 14,000*l.*, of which half was levied on the Dutch inhabitants, who were principally merchants that had been driven out of Flanders by the persecutions of the Duke of Alva, and had settled at Colchester. Two thousand pounds were afterwards returned to the inhabitants, but the poor Dutch were not allowed to have any part of it.

The ruins of the old castle, St. John's Abbey, St. Botolph's Priory, the Moot-hall, and its eight churches, form the principal antient and public buildings of Colchester. Of the walls by which the city was surrounded, in consideration of the repairing of which Richard II. is recorded to have exempted the burgesses from sending representatives to three of his Parliaments, only some detached portions now exist. They formed a circumference of one mile and three quarters. The remains of the castle stand upon an eminence to the north of the High Street, and form a parallelogram; the principal entrance is at the south-west corner, beneath a strong semicircular arch with capitals ornamented in the Norman style. The keep is still in a good state of preservation, and its walls are twelve feet thick. The building, which is a compound of flintstone and Roman brick, is so hard that it has frustrated repeated attempts to demolish it for the sake of the materials. The castle was formerly crown property, and the town was feudatory to it.

St. John's Abbey was founded by Eudo, dapifer or steward to Henry I., for monks of the Benedictine order. A handsome gateway, of the later style of English architecture, is all that now remains of this abbey. The last abbot was hanged for treason in 1539, and the site of the monastery passed into the family of the Lucases.

In St. Giles's church, adjoining the abbey, is a monument erected to the memory of Sir C. Lucas and Sir George Lisle. St. Botolph's Priory, not far from St. John's, was founded by Enulph in the beginning of the twelfth century. The remains of the western front of its stately church are highly interesting. A fine semicircular retiring arch, with various mouldings of small Roman bricks and stone alternately, forms the doorway.

Colchester has returned two members to Parliament since the 23rd of Edward I. At the first election after the passing of the Reform Act there were 1099 voters registered. The first charter granted to the corporation was by Richard I. in 1089. It was subsequently extended by Henry V., and renewed by George III. in 1818.

The Corporation hold quarterly Courts of Session for the borough and the liberties: and two Courts of Pleas for the recovery of debts to any amount; one called the law hundred, on Monday, for actions against burgesses, and one on Thursday, called the Foreign Court, for actions against strangers, or non-freemen. The Moot-hall is an antient building erected by Eudo, and contains the Hall and Exchequer Chamber, and the Council Chamber, where the business of the corporation is transacted. Underneath is the town gaol.

The town is built on the summit of an eminence gently rising from the river Colne, over which there are three bridges. The streets are wide and generally well paved, and the High Street contains some handsome houses and good shops. It is lighted with gas, and well supplied with water. The theatre is a neat building, erected in 1812. A literary and philosophical society was established in 1820; attached to it is a museum of shells, fossils, and natural objects. There are also a medical society, a botanical society, and a musical society of amateurs. The weaving of baizes, probably introduced by the Flemings in the time of Elizabeth, was carried on here to some extent, but it now has been succeeded by a large silk manufactory. The oyster fishery on the river Colne, granted to the burgesses by Richard I., employs a great number of men, and some hundreds of smacks are engaged in conveying the oysters to London, especially from Pyfleet. The river is navigable for vessels of 200 tons burden to the Hythe, where there is a custom-house and an extensive quay. The market-days are Saturday and Wednesday, for corn and cattle; but a market for meat, fish, and vegetables, is held daily. The fairs are on the 5th and 6th of July, and on the 23rd and 24th of July for cattle; and on the 20th of October for cattle, and three following days for merchandize. The population of the borough and liberties is 16,167, of whom 8696 are females; the population of the town itself is 13,766. There are 2079 families employed in manufactures, trade, &c., and 490 families employed in agriculture.

Colchester was made the seat of a suffragan bishop by Henry VIII., and two bishops were subsequently consecrated there. The church of St. James is a handsome building, erected prior to the reign of Edward II. It has a fine altar-piece representing the 'Adoration of the Shepherds.' St. Peter's was erected before the Conquest, and is mentioned in 'Domesday Book' as the only church in Colchester. It was greatly repaired and modernized in 1758, and large sums of money have been laid out on it since that time. The church of St. Leonard's is large and convenient. There are two places of worship for Baptists, two for Independents, and one for each of the societies of Friends, Wesleyan Methodists, and Unitarians.

The free grammar-school was founded by the corporation, to whom queen Elizabeth, in the 26th year of her reign, granted certain ecclesiastical revenues for that purpose. The number of scholars on the foundation is generally from thirty to forty; the present income is 117*l.* per annum.

Two charity schools for the education and clothing of fifty-five boys and thirty girls were established in 1708; several donations have been since made to these schools. The National School is formed by an extension of the original charity school, and about 400 boys are educated in it, of whom 148 are clothed. There are several schools supported by different dissenting congregations. A school for children of members of the Society of Friends was established in 1816, and endowed with a library and a large sum of money by John Kendall. There is also a Lancasterian school for children of both sexes, supported by voluntary contributions.

There are several alms-houses at Colchester. The Essex and Colchester General Hospital is a neat and commodious building, erected in 1820.

COLCHICA'CEÆ. [MELANTHACEÆ.]

CO'LCHICUM AUTUMNA'LE, or MEADOW SAFFRON, is a plant with a solid bulb-like rootstock, found wild in various parts of Europe, as well as in Great Britain, and forming a gay carpet in the autumn in the fields, where its lively purple crocus-like flowers spring up. Its underground stems, or bulbs, as they are called, and its seeds, abound in an acrid, stimulating, deleterious principle, which has been carefully examined by modern chemists, and forms an important plant in the Materia Medica, large quantities of both rootstocks and seeds being annually consumed in the manufacture of Eau Médicinale, and other medicinal preparations. Its bulb-like rootstock is irregularly egg-shaped, and covered with a dry, brittle, brown skin; at its base it bears a bud, which feeds upon the parent stock, exhausting and finally replacing it every year. Its flowers are large pale purple, and spring up in the autumn without leaves, forcing themselves readily through the soil, and expanding just their orifice, together with the anthers and stigmas, above the surface of the soil, while the tubular part, with the ovary and filaments remain enveloped in membranous sheathing spathes below the soil. Each stock produces six or eight of these flowers. The stamens are six, the ovaries three, each with a long thread-shaped style, and not adhering in any degree to the tube of the flower. These are succeeded by three little follicles, which slightly adhere to one another by their inner edge, and in the spring are elevated above the soil by their lengthened footstalk. At this time, too, the foliage makes its appearance in the form of an erect tuft of broad, oblong, shining, sheathing leaves. Each follicle contains several oblong seeds.

Colchicum is so very like an autumn crocus, that an inexperienced observer might readily mistake the one for the other. They are, however, to be distinguished by the crocus having only three stamens, one style, and an inferior ovary, while the colchicum has six stamens, three styles, and a superior ovary—distinctions of no little importance when the poisonous qualities of colchicum, in which the crocus does not at all participate, are considered.

For medical purposes, the rootstocks of colchicum should be collected at Midsummer, and they should be used immediately; for at that time the peculiar principles which they contain are in the greatest state of concentration. If they are employed at a time when the plant is in a state of growth, especially when it is coming into flower, those principles are partly lost and decomposed by the growth of the plant, and there is no certainty as to the quantity of veratria that a given weight of the rootstocks will yield.

Other species of colchicum are cultivated for the sake of their flowers, but they are of no medicinal importance, and are very badly distinguished from each other by botanists.

Three different parts of *Colchicum Autumnale* yield an active principle used in medicine, but they respectively contain it in the greatest intensity at different seasons of the year; the cormus (incorrectly called root or solid bulb) having it in perfection about June or July, the flowers in September, and the seeds the following spring. The cormus and seeds are most frequently employed in Britain; but should the proper period (Midsummer) for collecting the cormi be neglected, the flowers may be substituted, though they can only be put to immediate use, as they do not keep well. The cormi are found at various depths under ground; when very deep, they are not so good, being the produce of old exhausted plants. Each cormus is about the size of a hazel-nut or walnut, ovate or heart-shaped, consisting of a white fleshy succulent substance, which, when cut across, exhibits roundish plates. It is somewhat flatter on one side, on which also may be discovered a groove, in which is lodged the germ of the flower-stem of the following year. The recent cormus has a nauseous radish-like odour; when dried, no odour; the taste is sweetish-bitter, leaving an acrid sensation in the throat.

The seeds, which should be collected in May, are small, globose, about the size of a grain of millet, of an obscure fawn colour, opaque, rough, and wrinkled, with a white hilum at the base, very hard, tough, and difficult to reduce to powder. The relative proportions of the constituent ingredients of the cormus differ greatly, according to the season of the year when it is taken up for examination, as Stolze's analyses demonstrate. The active principle of colchicum was long considered to be the same as that of veratrum, and thence called veratria; but Geiger and Hesse have shown that it is different, and have termed it *colchicia*. The seeds contain this principle, and likewise some thick oil. Colchicum imparts its activity partially to water, but more so to acetic acid, proof spirit, and wine. A sirup is sometimes formed of it, but it does not keep well.

In a small dose, colchicum causes an increased flow of urine, and more frequent evacuations from the intestinal canal, and occasionally augmented secretion from the skin; in larger doses, frequent evacuations from the intestines, accompanied with pain and tenesmus, and desire repeatedly to empty the bladder. Still larger doses cause increase of all these actions, with vomiting and sense of burning in the throat, insensibility and stiffness of the tongue, escape of blood into the intestinal canal, vomiting of blood, and a flow of bloody urine. Great disturbance of the nervous system is likewise observed, as in other cases of poisoning with acrid substances. The same appearances are found in the intestinal canal, if the poison be injected into the veins.

Even the milk of cattle which have eaten the meadow-saffron becomes capable of causing death. (Vogt.)

In a moderate dose, colchicum seems to increase the quantity and improve the quality of all the secretions of the intestinal canal and the collatitious viscera, especially the liver; but it likewise exerts a sedative action on the heart. Chelius says that in twelve days it doubles the quantity of uric acid found in the urine, a circumstance which explains its utility in gout and rheumatism.

The diseases in which colchicum is most useful are, dropsy, when a small dose is prescribed; gout, in which larger are used; and rheumatism, in which its beneficial influence is first felt on the liver (which is almost always disordered in these diseases), and afterwards on the kidneys, from which a larger portion of uric acid is excreted, and the formation of gout-stones (urate of soda) in some degree prevented. As acid in the stomach renders the action of colchicum more violent, magnesia is usually given along with it. The acetate and acetous extract are the best forms of administration.

COLCHIS, a country of Asia, extending along the eastern shore of the Euxine Sea, from the town of Trapezus. (Strabo, p. 548, *d.*) It was bounded on the north by the Caucasus, on the south by Armenia, on the east by Iberia, and on the west by the Euxine. The modern Mingrelia includes only part of this country. The name Colchis appears in the early legends of the Greeks as connected with the expedition of the Argonauts [Argonauts], and the story of Jason and Medea.

The chief river of Colchis was the Phasis, which, receiving the small streams of the Glaucus and Hippus from the neighbouring mountains, flows into the Euxine sea. (Strabo, p. 498, *b.*) Among the most important cities were Pityus, the great mart of the district, Phasis, on the river of the same name, where the Argonauts are said to have landed, Aea on the Phasis, and Ceta. Colchis was a very fertile district and abounded in timber, which was well adapted for ship building, in various kinds of fruits, and in flax. The inhabitants were famed for their linen manufactures, which formed a considerable article of export. The honey, which Strabo (p. 498, *b*) represents as being very bitter, produced violent and even fatal effects on the Greeks who eat of it during the retreat of the Ten Thousand; it deprived them of their senses, disabled them from standing upright, and occasioned vomiting, &c., but finally all recovered. (Xenophon, *Anab.* iv. s. 20). The richness of the country in silver and gold mines, some of which are said to be worked with profit at this day, was probably the cause of the Argonautic expedition. The pheasant (*Phasiana avis*) derives its name from its native place, the banks of the Phasis.

The Colchi were originally from Egypt, according to Herodotus (ii. 104), and part of the army with which Sesostris invaded Scythia. The facts on which he founds his opinion are similarity of physical features, of language, and of peculiar customs, such as circumcision. The curled hair and swarthy complexion, on which Herodotus relies in support of his position, seem however no longer to exist in Mingrelia.

Colchis was governed by kings when we first read of it. Helius is mentioned by Diodorus as king before the Argonautic expedition. Æetes is mentioned by Strabo (p. 45, *d*) as king at the time of the expedition. Colchis was afterwards divided into several small kingdoms or states (Strabo, 45, *d*), and we hear nothing more of it till the time of Xenophon, who (*Anabasis*, v., 6, 37) speaks of a son or grandson of Æetes as reigning over the Phasiani. The Colchi were not then subjects of the Persian empire, but were independent. (Xen. *Anab.* vii. 8, 25.) They opposed the Greeks in the retreat of the Ten Thousand. Mithridates afterwards subdued Colchis, and the government was administered by præfects, one of whom, Moaphernes, was Strabo's uncle. (Strabo, p. 449, *a.*) Under the early emperors, the family of Polemon, a Greek rhetorician, reigned over the Colchians. (Strabo, p. 499, *a.*)

COLD, in Natural Philosophy. [Heat.]

COLD. [Catarrh.]

COLDEN, CADWALLADER, lieutenant-governor of New York before the revolution, was the author of numerous works on subjects in medicine, natural philosophy, and botany. His father was minister of Dunse in Scotland, where he was born in 1688. He received his medical education at the university of Edinburgh, and in 1708 he emigrated to Pennsylvania, where for several years he practised as a physician. After visiting England, and having established a reputation by 'Remarks on Animal Secretions,' he returned to Pennsylvania, and settled finally, in 1718, in New York, where he was appointed surveyor of the lands of the colony and master in chancery, with a seat in the king's council. His principal works are—'A History of the Five Indian Nations,' 'An Account of the Diseases then prevalent in America,' 'An Essay on the Cause and Remedy of the Yellow Fever, so fatal at New York in 1743;' 'A Treatise on Gravitation,' subsequently enlarged and republished as 'Principles of Action in Matter,' with a treatise annexed, on the 'Elements of Fluxions, or Differential Calculus;' 'An Introduction to Medicine,' 'Remarks on the Inaccuracy of the History of New York.' His favourite study was botany. The *Acta Upsaliensia* (for 17 3-4, *Plantæ Novæboracenses*) contain his descriptions of several hundred American plants, of which 200 were new species. He left a long series of meteorological observations, and a daily register of the thermometer and barometer; and several valuable MSS. on the vital movement, properties of light, intelligence of animals, and on the phenomena attending the mixture of metals. Among his correspondents were most of the leading scientific and learned characters of the age, as Franklin, the earl of Macclesfield, Gronovius, and especially Linnæus, who honoured him by naming a new species of plants *Coldenia.* He died at his seat on Long Island at the age of eighty-nine. (*Biographie Universelle; Encyclop. Americana.*)

COLE, COLZA, a cultivated state of the *Brassica Napus*, which does not form a close head, like cabbage, but has sessile heart-shaped leaves. It is cultivated for its seeds, from which an oil is expressed, which is much used for burning in lamps, and in the manufacture of leather and soap.

There are two varieties of cole, one with white flowers and another with yellow; the latter is the hardiest, and consequently most generally cultivated.

It requires a good loamy soil, well manured, to produce a good crop of cole seed. In rich land lately broken up from pasture, or fenny land newly drained, it grows luxuriantly and gives a great return. It is thought to be a great exhauster of the soil. In a rotation, cole is considered as a good crop to precede wheat. Like rape, which is another variety, it is sometimes sown to be fed off by cattle and sheep on land which is not so well adapted to the growth of turnips.

COLEO'PTERA (κολεόπτερα), in Entomology, a name first applied by Aristotle (*Hist. Anim.* i. &c.), and now universally adopted to designate one of the orders into which insects are divided, the species of which order are commonly known by the name of *Beetles.*

Nearly all true insects, or those annulose animals which have six legs, exhibit, in a more or less developed state, four wings, or members, which, although they may not enable the animal to fly, occupy the same situation, and are analogous to those which in many insects are true organs of flight.

These members are modified in various ways to suit the habits of the species or of the groups in general; but in those insects whose habits are of a nature not to require the power of flight they are very seldom entirely wanting, being found either in a rudimentary state, or modified in their structure so as to perform some other office. In those instances where the wings are only rudimentary, we cannot often assign any positive use for them; we can only perceive that the affinities of the individuals exercise an influence in these respects—that is to say, those species which belong to groups where the individuals generally possess perfect wings will often possess these members in a rudimentary state, when from their habits they do not require the power of flying*. It appeared necessary to make these few general remarks before proceeding to give the distinguishing characters of a coleopterous insect, in order that the nature of these characters and the departures from them might be understood; for it is difficult to give a strict definition of any group of animals.

The insects, then, which constitute the order Coleoptera may be characterized as having four wings, of which the two superior are not suited to flight, but form a covering and protection to the two inferior, and are of a hard and horny or parchment-like nature, and when closed, their inner margins, which are straight, touch and form a longitudinal suture (fig. 16, *c*); the inferior wings, when not

* The females of many moths have only rudimentary wings.

in use, are folded transversely under the superior, and are membranous. From this character of having the *wings in a sheath*, the term Coleoptera was applied, it being composed of the two Greek words κολεός, a *sheath*, and πτερά, *wings*. The superior wings, which form the sheath, are generally called elytra.

The principal exceptions to this general rule are as follows:—those beetles which have no under wings, or have them in a rudimentary state, as in Carabus cancellatus; and those in which the elytra are soldered together at the suture, in which case we believe no under wings are ever found. Another species of Carabus (*C. violaceus*) and many among the Heteromera afford examples of this exception. There are several beetles in which the elytra do not close at the suture, and in which the under wings are not protected by them. Such is the case in the genera *Sitaris, Ripiphorus*, and others in which the wing-cases, or elytra, are somewhat pointed; and in the genus *Molorchus*, among the Cerambycidæ, the wing-cases are very short, and the wings are not folded beneath them when at rest. In the Staphylinidæ the wing-cases are also very short, but the under wings, by a series of folds, are, when not in use, entirely concealed beneath them; and as in this tribe the elytra form a straight suture when closed, the only exception consists in the greater number of folds in the under-wings.

Numerous other exceptions might be noticed, but we will merely mention the genus *Meloe*, where one elytron partly folds over the other; the families Lampyridæ and Telephoridæ, in which the elytra are comparatively soft and flexible; and the glow-worm, the female of which beetle has neither elytra nor wings.

The larvæ of Coleopterous insects are generally composed of thirteen distinct segments, the head included. They are almost always of an elongate cylindrical or slightly depressed form; the body is often soft and fleshy, and of a white colour: in these the head is always of a firmer texture, being of a horny nature. The principal parts of the mouth are the same, as to number, as in the perfect insect, although the parts are (as far as our observations go) always differently formed. The head is furnished with two antennæ, which are generally minute, and composed of four joints; and ocelli, or simple eyes, on each side, situated near the base of the antenna. The body is furnished with six legs, which are attached, a pair to each of the three first segments, or those next the head: the legs are small, and usually terminated by a simple claw. Sometimes in addition to the ordinary legs, the larva is furnished with false legs (often termed pro-legs); these are fleshy tubercles which the animal can protrude at pleasure, and are used to propel the body. Some larvæ have only two of these pro-legs, which are attached to the apex of the terminal segment of the abdomen, or placed beneath that segment; and in the larvæ of the species of Cerambycidæ we find each segment of the body is thickened in the middle both above and below: these parts the animal has the power of protruding considerably, by which means it is enabled to thrust itself forwards or backwards in the holes in the trunks or boughs of trees which are formed by its feeding upon the wood.

The larvæ of groups (generally believed to be natural) very closely resemble each other, though those of different groups are sufficiently distinct: hence a knowledge of the larvæ is of great use in determining the natural affinities of species when their families or sections are not well ascertained.

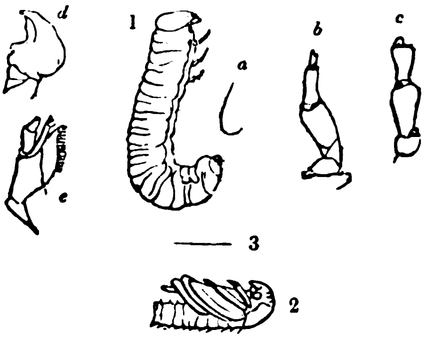

Fig. 1. Larva of a Coleopterous insect; *a*, natural size; *b*, leg; *c*, antenna; *d*, mandible; *e*, maxilla. *Fig.* 2. Pupa state of the same insect. *Fig.* 3. Natural size.

We select as an illustration of the principal characters of a Coleopterous larva, that of one of the Lamellicornes, a group which comprises the common cockchafer, and where the larvæ generally, if not always, have their body bent under at the apex.

We will now proceed to the pupa state of Coleopterous insects. Those larvæ that live in the ground generally prepare for the pupa state by removing the soil which surrounds them so as to form an open oval space: others form a species of cocoon around them, constructed of particles of earth, and other substances within reach, joined together by a kind of web or glutinous substance. Wood-feeding larvæ, or those that live in the trunks or bark of trees, for the most part assume the pupa state without such preparation.

Some larvæ which feed upon plants enclose themselves in a spherical cocoon; others again suspend themselves by the tail and hang from a leaf or stalk of the plant. In one instance we have known the animal to assume the pupa state within the skin of the larva [*]. The pupæ of Coleopterous insects are what is termed incomplete, *i.e.* all the parts of the perfect insect are distinctly visible, the legs, antennæ, wings, &c. being each enclosed in a separate sheath, and not, as in the pupa or chrysalis state of moths and butterflies, where all the parts are soldered together, or as in the pupæ of the Hemiptera (bug tribe), or Orthoptera (locust tribe), in which stage the insect is active, and in some instances cannot be distinguished from the perfect insect. This character, of *pupa incomplete*, is therefore one of great importance, and is generally added to the definition of a Coleopterous insect, for there are no other insects which, in the pupa state, are incomplete, and which, in the imago state could be confounded with the Coleoptera.

Having traced the beetle through the larva and pupa states, we arrive at the last or imago state, the perfect insect.

Beetles belong to the Mandibulata, which forms the first of the two great sections into which insects are divided: a section, the individuals of which are distinguished by their possessing distinct mandibles; and as the insects of the order Coleoptera possess the mandibles and all other parts of the mouth so well developed, they have by many been placed at the head of the insect tribe. We imagine, however, that the reasons stated for so doing are not sufficient [†].

It would require considerable space to enter into the anatomy of an insect: we will therefore at present confine ourselves to the external parts of a beetle, and to those only which it is essential to know, in order to understand the description of these insects.

When we look at a beetle, we perceive that it is composed of three distinct parts, the foremost of which is the head; the next is called the thorax; and the last the abdomen.

The head is furnished with two eyes, two antennæ, and the various parts of the mouth, called the trophi. The eyes are situated on each side of the head, and are generally prominent, and always convex masses composed of an immense number of lenses arranged closely together, so that their interstices form hexagons. These are technically termed compound eyes, and are of a circular or oval form, frequently kidney-shaped, and in some instances (as in the genus Tetrops among the Cerambycidæ) they are completely divided.

The antennæ in Coleopterous insects have their origin generally near the eyes, and are situated for the most part either between them or before them. They are generally composed of eleven joints; in many, however, this number cannot be traced, whilst in some few there appear to be twelve [‡]. The form of the antennæ is extremely variable, and will be best understood by an inspection of the following illustrations, among which will be found most of the more common forms, and some of the more extraordinary.

[*] Megatoma serra, a little beetle, allied to the Dermestes, the larva of which is described in the 'Entomological Magazine,' vol. ii. p. 373.

[†] It appears that among the various characters which distinguish insects from other invertebrate animals, the great perfection of instinct displayed by them is one of the most striking features; we imagine therefore that that tribe which exhibits this quality in the highest perfection, and at the same time, the species of which possess in a well-developed state all the principal parts found in insects, ought to be looked upon as the head, or typical, group.

The insects constituting the order Hymenoptera, since they have all the parts of the mouth at least as well developed as in the Coleoptera, possess four wings formed for flight (which beetles do not), and exhibit the highest degree of instinct, ought, in our opinion, to be considered as the head of the insect tribe.

[‡] In some of the species of the family Cerambycidæ.

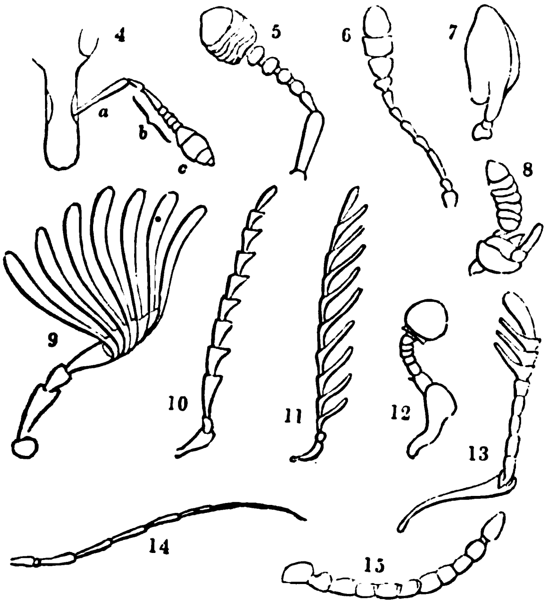

Fig. 4 represents the head (with one antenna attached) of one of the Curculionidæ, a large tribe of beetles, in which the antennæ are what is termed *geniculate**; that is, they have the terminal joints kneed, or bent at an angle with the basal joint. In describing beetles of this tribe, the antenna is generally divided into three parts. The long basal joint (*a*) is called the *scapus*, the several following joints (*b*) are termed the *funiculus*, and the terminal joints which form the knob (*c*) *clava*. *Figs.* 5 and 12 represent antennæ which are termed *capitate*, or which have the terminal joint or joints suddenly enlarged and forming a knob. When the knob exhibits distinct articulations (*fig.* 5), the antenna is termed *capitate with perfoliate knob*; and when the knob does not exhibit articulations, or is composed of a single joint, it is said to be *capitate with solid knob*. Examples of the former will be found in the genus Necrophorus, and of the latter in the genus Monotoma. *Fig.* 6 represents an antenna which becomes gradually thicker towards the apex, and which is termed *clavate*. *Fig.* 7 is the antenna of one of a most extraordinary group of beetles, the Pausidæ, many of which insects have the knob of that member swollen or inflated. *Fig.* 8 is an auriculate antenna, and is so called from its having an ear-like appendage at its base. This description of antenna is found in the genera *Parnus* and *Gyrinus*. *Fig.* 9 represents the antenna of the common cockchafer (Melolontha vulgaris). This form of antenna, which is termed lamellate† is found throughout the immense tribe of beetles called by Linnæus *Scarabæus*, and which has received the name of Lamellicornes from this peculiar character.

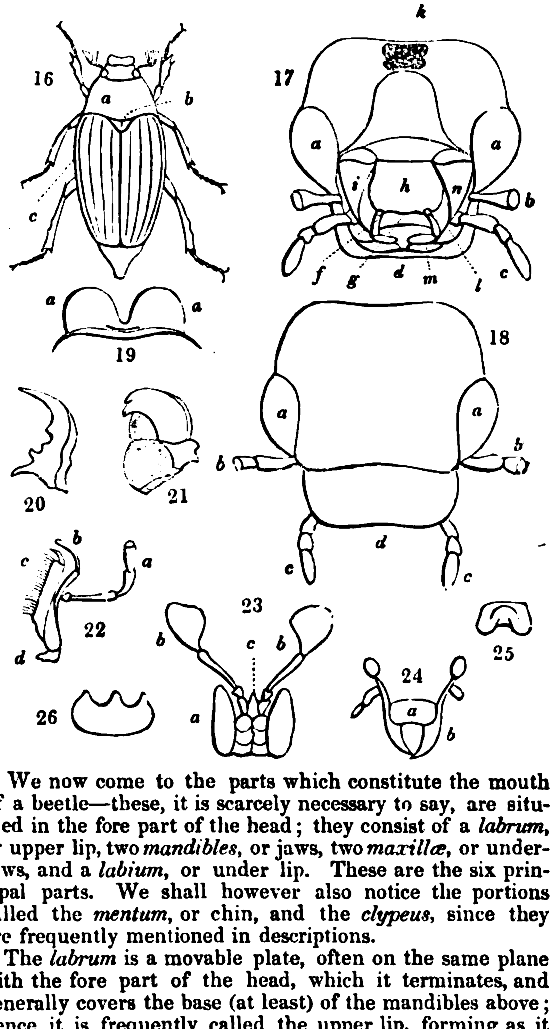
It must be observed however that slight modifications are found. *Fig.* 10 is a figure of a serrate antenna. Antennæ are so called when they have the apex of the joints widened, so as to resemble the teeth of a saw. Examples may be found in the Elateridæ and Buprestidæ. Pectinate antennæ (*fig.* 11) are those in which the apex of the joints is produced on one side, and which somewhat resemble the teeth of a comb. There are many examples of this structure in the antennæ of the Lampyridæ, &c., and there are some in which the joints are elongated on each side: these are termed *bipectinate*. *Fig.* 13 is what is called a fissate antenna (the joints on one side divided as by incisures). This form of antenna is found in the genus Lucanus. *Fig.* 14 represents a very common form of antenna (where it is slender and tapering gradually to the apex); it is termed *setaceous*, and most of the Carabidæ and Cerambycidæ will afford examples. The antennæ termed *filiform* somewhat resemble the last, but the joints are all of equal thickness throughout. The last description of antennæ which we shall notice are those termed *moniliform* (*fig.* 15). Here all the joints are oval or round, and resemble a necklace of beads. Examples are found in many of the species of the section Heteromera.

There are many other variations in the antennæ of Coleopterous insects which might be noticed, and for descriptions of which we refer our readers to Kirby and Spence's *Introduction to Entomology*, vol. iv., p. 324. Most of those here noticed are the more common forms, and occur frequently in our descriptions of insects of this tribe.



We now come to the parts which constitute the mouth of a beetle—these, it is scarcely necessary to say, are situated in the fore part of the head; they consist of a *labrum*, or upper lip, two *mandibles*, or jaws, two *maxillæ*, or under-jaws, and a *labium*, or under lip. These are the six principal parts. We shall however also notice the portions called the *mentum*, or chin, and the *clypeus*, since they are frequently mentioned in descriptions.

The *labrum* is a movable plate, often on the same plane with the fore part of the head, which it terminates, and generally covers the base (at least) of the mandibles above; hence it is frequently called the upper lip, forming as it does the upper boundary of the mouth.

This portion, although of various forms, is less liable to variation than most of the other parts of the mouth. The most common form perhaps is somewhat quadrate, or broader than long, as in *fig.* 24, *a*.

Upon referring to the article CARABUS, it will be seen that that genus and some other closely allied genera are separated chiefly on account of the difference in the form of this member. In one it is described as bilobate; by this is meant, that the labrum is notched in the middle, so that the two side pieces form lobes (see *fig.* 25). When the labrum is not thus notched, but presents an even anterior margin, it is described as *entire*. In one of the other genera (*Procrustes*), where the labrum is described as *trilobate*, the only difference consists in its having two notches on the anterior parts, and thus separated as it were into three lobes.

The *clypeus* is the part to which the labrum is attached, and which is usually on the same plane with it. The term *Clypeus* will seldom be found in descriptions, excepting in giving the characters of those beetles which belong to the Lamellicornes, a tribe in which this part is greatly developed (*figs.* 17 and 18, *d*), and where the labrum is hidden beneath it.

Under the labrum, the mandibles (*mandibulæ*) are situated. These, as their name implies, are the organs of manducation; they move horizontally, and are most commonly of a shape more or less approaching to a triangle. Their form however varies according to the food of the insect.

---

* In Kirby and Spence's 'Introduction to Entomology,' the antennæ of the Curculionidæ are termed *Antennæ fractæ*; *Antennæ geniculatæ* being applied to such as the antennæ of the Meloe. The above, however, is the more common application of the term.

† From Lamellæ, layers.

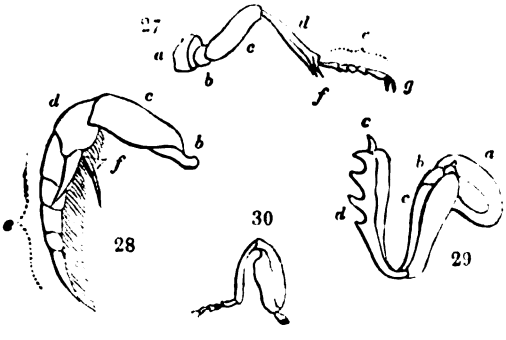
Generally speaking, in beetles which feed upon vegetable substances the jaws are broad, obtusely pointed at the apex, and have moreover a broad flat surface at their base (often with little sharp ridges), which somewhat resembles a molar tooth of herbivorous quadrupeds. (See *fig.* 21.) In those species whose habits are carnivorous, the jaws are longer and less stout, have the apex acutely pointed, and several sharp tooth-like processes on their inner side. (See *fig.* 20.)

Next in succession follow the *maxillæ*, or under jaws (*fig.* 17, *n*, and *fig.* 22): these organs are situated beneath the mandibles, and, like them, move horizontally. A typical maxilla consists of several parts, the principal of which are, the hinge (*cardo*), a piece situated at the base of the maxilla (*fig.* 22, *d*), the maxillary palpus (*fig.* 22, *a*), an articulated organ generally composed of four joints, the outer lobe (*lobus superior*), which in beetles of carnivorous habits is a two-jointed process (*fig.* 22, *b*) situated between the maxillary palpus and the inferior lobe (*lobus inferior*), which last portion constitutes the inner part of the maxilla, and is often formed like the blade of a knife, and furnished generally with a series of bristles or hairs on the inner edge. (See *fig.* 22, *c*.) The maxillæ seem to be used with the labium in directing the food during manducation, and the bristles on the inner edge appear to serve as a kind of strainer through which the juices are pressed, for we observe that solid substances are seldom swallowed by insects in their imago state.

The *labium*, or under lip (*fig.* 17, *h* and *g*, and *figs.* 23 and 26), is a movable organ which serves to close the mouth beneath, and is generally divided by a transverse suture, in which case the lower portion constitutes the *mentum*, or chin. The tongue (*fig.* 23, *c*), which may be considered as a portion of the labium, in Coleopterous insects, is usually situated at the apex of that member, or emerging from it. The *labial palpi* (*fig.* 23, *b*, *b*, and *fig.* 17, *f*) are two articulated organs, usually springing from the summit of the labium on each side.

Having now briefly noticed the head and its parts, we come to the thorax. On this portion it will be unnecessary to dwell: we need only mention that the thorax in insects is composed of the three first segments of the body, which in the larva state are usually distinct; these are termed the *prothorax*, *mesothorax*, and *metathorax*; and it generally happens that in the perfect insect one of these segments is greatly developed at the expense of the other two, particularly on the upper surface of the body; such is the case in the Beetle tribe, where the first portion or prothorax *fig.* 16, *a*) and the small plate (*fig.* 16, *b*), which is a part of the mesothorax, are all that is visible from above when the elytra are closed. Some few entomologists, therefore, in describing beetles, call the part (*fig.* 16, *a*) the prothorax, but it is most commonly called the thorax. The small plate (*fig.* 16, *b*) above referred to is called the scutellum, and is usually of a triangular form.

To the thorax are attached the legs and wings: the anterior pair of legs are attached to the prothorax; to the mesothorax the intermediate pair of legs and the anterior pair of wings, or elytra, as they are termed in the Coleoptera; and to the metathorax, the posterior pair of legs and the hinder pair of wings. Of the wings enough has been said for the present



The legs in beetles vary according to their habits: thus in some they are formed for running (*fig.* 27), in others for swimming (*fig.* 28); here they are very broad and flat; in others again their structure is suited to burrowing habits (*fig.* 29); and *fig.* 30 represents the hind leg of a beetle, which has the power of leaping to a great distance, where the thigh is very large.

A leg may be divided into five principal parts: the *coxa* or hip (*a*, *figs.* 27 and 29), which is the first joint, or that joined to the body, where it plays in a socket; the next part or second joint of the leg is the *trochanter* (*b*, *figs.* 27, 28, and 29); the third is the *femur* or thigh (*c*, *figs.* 27, 28, and 29); the fourth joint is called the *tibia* or shank (*d*, *figs.* 27, 28, and 29); the fifth and last part is the *tarsus* (*e*, *figs.* 27, 28, and 29); this part, in a great portion of the Coleopterous insects, is composed of five joints; in many a lesser number is found, but in none do they exceed five: the last joint of the tarsus is usually terminated by two hooked claws called *unguiculi* (*g*, *fig.* 27), and the apex of the tibia is furnished generally with two straight spines called the *calcaria*. (See *f*, *figs.* 27 and 28.)

The object in noticing the above parts of a Coleopterous insect is principally to make our descriptions of the species of this order intelligible to the general reader; and as the abdomen offers nothing of consequence, or rather nothing but what may be understood by its description under the various heads, we refrain from making any further remarks on the anatomy of the Coleoptera in this article, and now proceed to the classification.

As regards the classification of the Coleoptera, as well as of insects in general, in almost every work which treats of the subject, a new method is proposed. We shall content ourselves, however, with noticing two—that which is most commonly adopted on the continent, and that which is followed by most entomologists of our own country; the former is the method proposed by Latreille, and the latter that by Mr. Stephens.

In the classification of the Coleoptera, published by Mr. Stephens in his 'Systematic Catalogue of British Insects,' the various sections and subsections are as follows.

Order, Coleoptera.

Sect. 1. Adephaga
  Subsect. 1. Geodephaga
    2. Hydradephaga
    3. Philhydrida
    4. Necrophaga
Sect. 2. Chilognathomorpha
  Subsect. 1. Clavicornes
    2. Lamellicornes
    3. Sternoxi
    4. Malacodermi
Sect. 3. Helminthomorpha
  Subsect. 1. Rhinchophora
    2. Longicornes
Sect. 4. Anoplurimorpha
  Subsect. 1. Eupoda
    2. Cyclica
    3. Trimeri
Sect. 5. Heteromera
Sect. 6. Brachelytra

The arrangement of Latreille is founded upon the number of joints of the tarsi; he accordingly divides beetles into the four following great sections:—

Section 1. Pentamera, including all those beetles which have five joints to their tarsi.
Section 2. Heteromera, beetles with five joints to the tarsi of the two anterior pairs of legs, and four to those of the posterior pair.
Section 3. Tetramera, beetles with only four distinct joints to all the tarsi.
Section 4. Trimeri, beetles with only three distinct joints to the tarsi*.

On comparing these two arrangements, it appears that there is considerable difference of opinion between the authors of them as to the value of certain groups. The Trimeri, according to Latreille, is made one of the four great sections, whilst Mr. Stephens makes the same group a subsection of a tribe of not equal importance with Latreille's first division, the *Pentamera*.

These discrepancies probably arise from the want of some standard by which the importance of characters may be estimated. We find a great number of insects possessing certain characters in common, but it often happens that we cannot ascertain what influence these characters have on the habits and economy of the individuals. In such instances, the most correct way perhaps would be to judge of the value of a character by its constancy; or, in other words, to consider that character of most importance, as regards classification, which is found in the greatest number of species, these species agreeing more or less in some other points.

---

* In the two latter sections there is a minute rudimentary joint at the base of the terminal one.

In all groups of animals there are, however, certain typical characters to which all the species approach more or less, and which perhaps the greater portion actually possess. The typical characters of a group, and the departures from them, ought not therefore to be selected for constructing natural and equivalent groups. In the Coleoptera, for instance, the typical structure is to possess five joints to the tarsi; Latreille's first section (the *Pentamera*) consequently comprises at least half the species and several distinct groups, each of which is equivalent to one of his other sections.

It appears to us, being guided by the points above mentioned, that the order Coleoptera contains the thirteen following distinct sections, and that Latreille's groups are not natural.

All the Tarsi with five joints.

Section 1. Geodephaga, *Mac Leay*.
2. Hydradephaga, *Mac L.*
3. Brachelytra, *Latreille*.
4. Necrophaga, *Mac L.*
5. Palpicornes, *Lat.*
6. Lamellicornes, *Lat.*
7. Sternoxi, *Lat.*
8. Malacodermi, *Lat.*

Five joints to the tarsi of the two anterior pairs of legs, and four to the posterior pair.

9. Heteromera, *Lat.*

All the Tarsi with four joints.

10. Rhyncophora, *Lat.*
11. Longicornes, *Lat.*
12. Cyclica, *Lat.*

All the Tarsi with three joints.

13. Trimeri, *Lat.*

The number of species of beetles in existence may probably amount to between thirty and forty thousand.

The principal works on the Coleoptera are as follows:—Fabricius (J. C.), 'Systema Eleutheratorum;' Olivier (A. T.), 'Entomologie, ou Histoire Naturelle des Insectes,' 5 vols. folio, with coloured plates; Paykul (Gustavus), 'Fauna Suecica,' 3 vols.; Gyllenhal (L.), 'Insecta Suecica;' Schœnherr (C. J.), 'Genera et Species Curculionidum;' Dejean, 'Species général des Coléoptères;' five volumes of this work are published, and contain descriptions of the genera and species of the Carabidæ and Cicindelidæ. Besides these, the works of Germar, Illiger, Sturm, Knoch, and Duftschmid may be consulted; and the Coleoptera of our own country will be found described in Stephens's 'Illustrations of British Entomology.'

COLERIDGE, SAMUEL TAYLOR, was born at Ottery St. Mary in Devonshire, of which parish his father was the vicar, on the 21st October, 1772. He was the youngest of a numerous family, and became an orphan at the age of nine. Owing to the straitened circumstances of his family, he was sent to be educated at Christ's Hospital, where the late Charles Lamb was among his contemporaries. Here he made very great progress in classical knowledge; as may be inferred from the fact that he had, before his fifteenth year, translated the hymns of Synesius into English Anacreontics. His choice of these hymns for translation is explained by his having, even at that early age, plunged deeply into metaphysics. Speaking of himself in the 'Biographia Literaria' (vol. i. p. 15), he says, 'At a very premature age, even before my fifteenth year, I had bewildered myself in metaphysics and in theological controversy. Nothing else pleased me. History and particular facts lost all interest in my mind. Poetry itself, yea, novels and romances, became insipid to me.' From such pursuits he was however weaned for a time, while yet at Christ's Hospital, by the perusal of Mr. Bowles's Sonnets, which had then just been published. The powerful influence which these sonnets exercised upon his mind is described at length in the first chapter of the 'Biographia Literaria.'

In 1791 Coleridge entered Jesus College, Cambridge. While at the university, he did not turn his attention at all to mathematics; but obtained a prize for a Greek ode, and distinguished himself in a contest for the Craven scholarship, in which Dr. Butler, the present bishop of Lichfield, was the successful candidate. He did not take a degree. During the second year of his residence he suddenly left the university in a fit of despondency, occasioned, it is said, by unrequited love; and after wandering for a while about the streets of London in extreme pecuniary distress, terminated this adventure by enlisting in the 15th dragoons, under the assumed name of Comberback. One of the officers, accidentally discovering his classical acquirements, was led to conclude that Comberback was something more than he professed. Questioning him in a friendly manner, and eliciting his real history, he communicated Coleridge's situation to his friends, who forthwith effected his discharge.

Coleridge now betook himself to Bristol, where Mr. Southey was then residing. He shortly after set on foot a periodical entitled the 'Watchman,' which was to advocate liberal opinions; and made a tour through the northern manufacturing towns for the purpose of canvassing for subscribers. An account of this tour, amusing on the whole, is contained in the 10th chapter of the 'Biographia Literaria.' The periodical, owing partly to a want of punctuality in its appearance, and partly to the fact that its opinions were not those which its supporters had expected, did not live beyond the ninth number.

In the autumn of 1795 Coleridge married Miss Sarah Fricker of Bristol, Southey on the same day wedding himself to her sister. He now took a cottage at Nether Stowey, a village at the foot of the Quantock Hills, in Somersetshire, where he was in the immediate neighbourhood of his friend and benefactor, Mr. Poole, and of Mr. Wordsworth, who was then living at All-Foxden. He was at this time in the habit of contributing verses to one of the London papers, as a means of subsistence. In 1796 he published a volume of poems, the greater number of which had been written at earlier periods, interspersed with some by Charles Lamb; and in 1797 a second edition appeared, with the addition of some poems by Charles Lloyd*.

During the three years, moreover, in which Coleridge resided at Nether Stowey, the greater part of his principal poems was composed, though most of them were not published until later. In the conversations on poetry which constantly took place between Mr. Wordsworth and himself was first formed the plan of the afterwards famous Lyrical Ballads; and in pursuance of this the 'Ancient Mariner' and the first part of 'Christabel' were written in 1797. His tragedy, 'The Remorse,' was also written at this period.

Coleridge was at this period of his life a unitarian. He says of himself, 'I was at that time and long after, though a trinitarian (*i. e. ad normam Platonis*) in philosophy, yet a zealous unitarian in religion; more accurately, I was a *psilanthropist*, one of those who believe our Lord to have been the real son of Joseph, and who lay the main stress on the resurrection rather than the crucifixion.' (*Biogr. Lit.*, vol. i., p. 168.) While at Nether Stowey, he used to preach in a unitarian chapel at Taunton.

In 1798 Coleridge was enabled, through the munificence of the late Mr. Thomas Wedgwood, to visit Germany, for the purpose, as he expresses it, of finishing his education. At Göttingen he attended Blumenbach's lectures on physiology and natural history, and studied, in the notes of a young German student, Eichhorn's lectures on the New Testament. He took lessons from Professor Tychsen in the Gothic of Ulphilas, being anxious to attain a critical knowledge of the German language; and went through a complete historical course of German literature. His acquaintance with the writings of the later German metaphysicians was not formed until some time after his return to England.

After his return from Germany, Coleridge resided at the Lakes, where Mr. Southey and Mr. Wordsworth had then settled, the one at Keswick, and the other at Grasmere. The appellation of Lake-poets, given to these three individuals after the publication of the 'Lyrical Ballads,' is well known.

Coleridge now became connected with the Morning Post, and wrote both on politics and literature. From about 1808 to about 1814 he contributed to the Courier. In 1804 he had visited his friend Dr. Stoddart at Malta; and from May of that year to October of the next, he acted as secretary to Sir Alexander Ball, then governor of the island. After his return to England in 1808, he delivered a course of lectures on poetry and the fine arts at the Royal Institution. The 'Friend' appeared in the course of the next year, being then published as a periodical at the Lakes. As a pecuniary speculation it was not much more successful than the 'Watchman,' nor with reference to pecuniary advantage was it more judiciously conducted; but it continued for a longer time. Mr. Wordsworth gave some literary assistance, contributing the 'Essay on Epitaphs,' which is now appended to the 'Excursion,' and the 'Introductory Essay' of the third volume.

---

* It is stated in the 'Biographia Literaria' (vol. i., p. 2), that this volume of poems appeared in 1794. The title-page of the earliest edition that we have been able to find (and the absence of the words 'second edition' from the same title-page renders it improbable that there should have been an earlier edition than this) says 1796.

Coleridge left the Lakes in 1810, and did not afterwards return to them. On his first arrival in London he resided with Mr. Basil Montagu; and not long afterwards became the guest of Mr. Gillman at Highgate, in whose house he died. The many friendships which Coleridge attracted to himself through life, the sincerity and constancy of which were abundantly shown, place in a striking light the amiability of his character.

It was not before the commencement of his residence in London that he formed any very extensive acquaintance with the writings of the later German metaphysicians; by the adoption of whose method and terminology, rather than by any development of a system, in his subsequent publications, he has come to be accounted the representative of German metaphysics among us. He published successively, between the years 1817 and 1825, the two 'Lay-Sermons,' the 'Biographia Literaria,' the *rifaccimento* of the 'Friend,' the 'Constitution of the Church and State according to the Idea of each,' and the 'Aids to Reflection.'

Coleridge having no profession, slothful and imprudent, was during the greater part of his life in pecuniary distress. After his connexion with the newspaper-press had ceased, and his remaining hopes of self-support were derived from his later poetical and prose publications, his publisher became a bankrupt in 1819. This was a severe blow to Coleridge. The dependent situation in which it placed him preyed much upon his mind. We see him, in the collection of his letters which has been lately published, projecting various schemes to relieve himself. One of these was a scheme of systematic contribution to Blackwood's Magazine, the publisher of which was his friend. Accordingly, No. 1 of a 'Selection from Mr. Coleridge's Literary Correspondence' appeared in the number of that Magazine for October, 1821, and was to have been followed by a sketch of the history and philosophy of Superstition, with other interesting disquisitions. But the No. 2 never appeared. Continued ill health, combined with, and to a certain extent caused by, a habit of using opium which Coleridge had contracted, having originally resorted to it, under a mistaken notion, for medicinal purposes, had taken away from him by this time even what little amount of perseverance he might once have possessed*.

On the incorporation of the Royal Society of Literature by George IV. in 1825, Coleridge was selected as one of the ten Royal Associates, and as such received from that time 100 guineas a year out of the king's private purse. The annuity was withdrawn at the commencement of the present reign.

In his later years Coleridge was in the habit of holding weekly *conversazioni* at Mr. Gillman's house in Highgate. Those who knew little else of Coleridge are familiar by report with his extraordinary conversational powers. Of these the two volumes of 'Table Talk,' which have been published give no adequate notion. His conversation was not in fragments, but was wont to continue without aid from others, in the way either of suggestion or of contradiction, for hours at a time. All things human and divine, joined with one another by subtlest links, entered into his discourse; which, though employed upon abstrusest subjects, was a spell whose fascination even the most dull or ignorant could not resist.

In June, 1833, Coleridge was present at the meeting of the British Association of Science held that year in Cambridge. He died on the 25th July, 1834, in his 62nd year.

Though not a man of strong character, Coleridge possessed many amiable qualities. He had all the social affections strongly developed. Though he was not, in our opinion, eminently successful in attaining it, he had an earnest desire of truth. Thus he was by nature tolerant. But in his later years disease seems to have engendered an asperity in judging of the motives of others which was by no means consonant with the tenor of his earlier publications. To the same cause must be assigned a querulousness of disposition, which is exhibited in almost all his prose writings.

He was in person, as Mr. Wordsworth has described him, 'a noticeable man with large grey eyes.'

As a writer, Coleridge is to be viewed principally under two aspects: as a poet, and as the author of certain prose writings which, though miscellaneous in character, are chiefly employed upon metaphysical subjects.

As a poet, he was for a long time coupled, owing to the joint publication of the Lyrical Ballads and other accidental circumstances, with Mr. Wordsworth. Now that the derision against the Lake-school, eminently unjust as falling chiefly upon Mr. Wordsworth, has died away, the force of reaction has supplied a tendency, also erroneous in our opinion, as far as Coleridge is concerned, to run into the opposite extreme of admiration. In his translation of Schiller's 'Wallenstein' he has displayed taste and judgment of a high order. His own tragedies, the 'Remorse' and 'Zapolya,' contain many passages excellent for the apt expression of just thoughts and tender feelings. The 'Ancient Mariner' is a successful effort of fancy, in a region which had not before been tried: and the 'Christabel' contains a highly-wrought passage on divided friendship, which those who have once read cannot forget. In some of his smaller poems again a happy conceit is happily developed. But he is a poet of art rather than of nature. He has himself frequently admitted that his earlier poems are faulty, by reason of turgidness of style. It may be added that they show few signs of an original genius. There is none of that freshness and individuality about them which have always marked the earliest efforts of great poets, which (to confine ourselves to modern instances) are seen in all the poems of Wordsworth and Shelley, and in a most remarkable degree in the lately-published poems of Mr. Tennyson. And even in that department of poetic art which pertains to melody, in which we admit Coleridge's excellence, we deem the Choric Song in Tennyson's 'Lotos-Eaters' far superior to Coleridge's 'Kubla Khan.'

As regards the attainment of their chief professed end, or the advancement of mental, moral, and political science, we consider Coleridge's prose writings of little or no value. To overthrow the ascendency of Locke and Paley was, we learn from himself, the object of his ambition. In the first place, we approve not of such an object; in the second place, we assert that next to nothing was done towards its accomplishment.

In mental science, or psychology, he espoused a particular hypothesis (that propounded by Schelling) of the *absolute*. Now Schelling and Fichte and Cousin, and other philosophers of this school, appear to us to have perverted psychology as completely as, and more perniciously than, the Materialists. Each set of philosophers have transcended the limits of consciousness, and have left observation for conjecture. But, apart from the system itself, Coleridge has done little either to advance or diffuse it. As he got it from Germany, so has he left it*; and his writings, from their method and style, are not fitted for the use of learners.

---

* One among the many inaccuracies into which the English Opium-eater (Mr De Quincey) has fallen in his articles on Coleridge in Tait's Magazine, is a statement that Coleridge first resorted to opium for the pleasurable excitement which it affords. This statement has been contradicted by the editor of Coleridge's Table-Talk, who also informs us that Coleridge had entirely conquered the habit some time before his death.

* The passage in Coleridge's writings which approaches nearest to a systematic exposition of his views, viz., the 12th chapter of the 'Biographia Literaria,' is little more than a translation from the introduction to Schelling's 'System of Transcendental Idealism.' Mr. De Quincey (Tait's Magazine, Sept., 1834) has, in respect of this passage, charged Coleridge with plagiarism from Schelling. Professing to bring five instances, of which this is one, of unavowed obligation to other writers, he has founded upon these a charge of habitual plagiarism.

As regards the particular charge, which relates to this passage in the 'Biographia Literaria,' the observations which are made concerning Schelling in the preceding chapter, and which have been misrepresented by Mr. De Quincey, acquit Coleridge of plagiarism.

As regards the general charge, the instances brought forward are also inadequate to its establishment. One of them, that concerning the interpretation of the Pythagorean caution against beans, is altogether frivolous. The next, though they are not adequate to establish a habit of plagiarism, are adequate to prove that Coleridge was accustomed to trust to others for suggestions upon which he improved, and for ideas which he elaborated. Of this habit another instance is supplied by Alvar's dungeon soliloquy in the 'Remorse' (act v., scene 1), the ideas, and to a certain extent, the words of which are derived from Caleb's prison soliloquy in Godwin's 'Caleb Williams.' The anecdote concerning the origin of the 'Ancient Mariner,' and Coleridge's denial of it (which anecdote neither Mr. Hare nor Mr. Nelson Coleridge have given any reason for disbelieving), are eminently characteristic of a person having this habit. The habit may be partly accounted for by indolence. It is chiefly to be explained, we believe, by the fact that Coleridge's was not properly an original mind.

In moral science, which, properly speaking, is no other than what Hobbes long ago stated it to be, the science of what is just and what is unjust, and which, thus viewed, has been significantly named Deontology by Mr. Bentham, Coleridge also followed the later German metaphysicians. These make moral science a part of, and in fact confound it with, psychology. In following them he thought it necessary to declare eternal warfare against the school of writers who have been absurdly named 'Utilitarians.' He contends for a something within us which, 'being absolutely *unique*, no man can *describe*' (*Friend*, vol. i., p. 256), which 'bearing the same relation to God that an accurate timepiece bears to the sun,' faithfully tells God's will, and which has the various names of 'universal reason,' 'practical reason,' 'moral sense,' 'moral instinct,' 'conscience.' 'Good and evil,' 'just and unjust,' are determined by the decisions, from which there is no appeal, of this inward monitor. This system professes to be diametrically opposed to that which makes the whole tendency of an action to affect men's happiness, or the sum of possible consequences in respect of general happiness, the principle of morality. Yet its professors cannot stir beyond the bare enunciation of their own principle without drawing for aid upon the principle which they impugn. But, inasmuch as they disavow this aid, their system comes before us as one continued *petitio principii*.

Coleridge's political doctrines are explained in the first section of the 'Friend.' This section is but one series of confusions and mis-statements. In the very outset the phrases 'political justice' and 'origin of government' are used as convertible expressions. Hobbes is made to deny *right* and *duty*. Rousseau's theory of a social contract, as explanatory of the origin of government, is accounted proof that he could not and did not admit expediency as the principle by which the government when formed should be guided. Other similar instances might be easily cited.

Yet there is not one of Coleridge's prose writings which has not incidental merits sufficiently many and great to rescue it from oblivion—merits discernible either in scattered criticisms on our older writers both of poetry and prose, or in illustrations drawn from stores of knowledge which a very wide reading had amassed, or in passages of great acuteness and sound practical wisdom, whenever the author lowers his flight to subjects to which such qualities can be applied with any hope of profit. And though, from the combined effects of indolence and of an intense devotion to conversational display, his ordinary style of writing is rambling and obscure, these works contain occasional passages of great beauty and power. In treating lighter subjects, his style may even be pronounced happy. Witness his account of Sir Alexander Ball in the third, and the tale of Maria Schöning in the second, 'Landing-place' of the 'Friend.'

Coleridge's fame will principally rest upon his powers as a critic in poetry and the fine arts. To establish his fame in this respect, there are his Lectures delivered at the Royal Institution (just published in the 2nd volume of Coleridge's 'Literary Remains'), his review of Mr. Wordsworth's poetry, in the 2nd volume of the 'Biographia Literaria,' which is perhaps the most philosophical piece of criticism extant in the language, and also his review of Mr. Maturin's 'Bertram,' which, though, when first published, it exposed him to much obloquy and many imputations of jealousy, is distinguished from common criticisms, if by nothing else, by a constant reference to first principles and a freedom from personality.

We do not place Coleridge in the first class of thinkers and writers; nor do we consider his to have been, in any high degree, an original mind. In support of this opinion, our limits will now only allow us to adduce the two following considerations. First, he was ever changing his opinions: and each new opinion, bringing with it a new idol, was preached with the utmost extravagance until it was in its turn displaced by another. Secondly, one fault which pervades his prose writings is an excess of quotation. They are the works (and, so far as this implies praise, we most willingly concede it) of a man of very extensive reading; but they are also the works of one who requires something from another whereon to hang whatever he may himself have to say.

COLET, JOHN, the founder of St. Paul's School, was born in the parish of St. Antholin, London, in 1466, and was the eldest son of Sir Henry Colet, Knight, twice Lord Mayor, who had, besides him, twenty-one children. In 1483 he was sent to Magdalen College, Oxford, where he passed seven years, and took the usual degrees in arts. Here he studied Latin, with some of the Greek authors through a Latin medium, and mathematics. Having thus laid a good foundation of learning at home, he travelled abroad for further improvement: first to France, and then to Italy, in which two countries he continued from 1493 to 1497. Before his departure however, and indeed when only of two years standing in the university, he was instituted to the rectory of Denington in Suffolk, being then in acolythe's orders, to which he was presented by a relation of his mother, and which he held till his death. His father also presented him in 1485 to the rectory of Thyrning, in Huntingdonshire, which he resigned in 1493. At Paris he became acquainted with Budæus, and was afterwards introduced to Erasmus. In Italy he contracted a friendship with numerous eminent persons, and especially with some of his own countrymen, among whom were Grocyn, Linacre, Lilly, and Latimer, all of whom were studying the Greek language, then but little known in England. Whilst abroad he devoted himself chiefly to divinity and the study of the civil and canon law. During his absence from England he was made a prebendary of York in 1497, and was also made a canon and prebendary of St. Martin's-le-Grand in London. He returned in this year, and was ordained deacon; taking priest's orders in the following year. Soon after this he retired to Oxford, where Erasmus came, and renewed his friendship with him. In Oxford he read public lectures upon St. Paul's Epistles gratuitously. In 1502, having proceeded in divinity, he became prebendary of Durnsford in the church of Salisbury, and in 1504 resigned his prebend at St. Martin's-le-Grand. In the same year he commenced D.D. In May, 1505, he was instituted to the prebendary of Mora in St. Paul's, London, and in the same year and month was appointed Dean. In this office he reformed the decayed discipline of his cathedral, and introduced a new practice of preaching himself upon Sundays and great festivals. By his own, and by other lectures which he caused to be read there, he mainly assisted in raising that spirit of inquiry after the holy Scriptures which eventually produced the Reformation; but the contempt which he avowed for the abuses in religious houses, his aversion to the celibacy of the clergy, and the general freedom of his opinions, made him obnoxious to some of the clergy, and especially to Fitzjames, then bishop of London, who accused him to Archbishop Warham as a dangerous man, and even preferred articles against him. Warham however dismissed the case. From Bishop Latimer's sermons it should seem that Fitzjames afterwards tried to stir up the king and court against him. Tired with trouble and persecution, Colet began to think of retiring from the world. He had now an ample estate, without any near relations, for numerous as his brethren had been, he had outlived them all. He resolved therefore, in the midst of life and health, to consecrate his fortune to some lasting benefaction, which he performed in the foundation of St. Paul's School, of which he appointed William Lilly first master in 1512. He ordained that there should be in this school a high master, a sur-master, and a chaplain, who should teach gratis a hundred and fifty-three children, divided into eight classes; and he endowed it with lands and houses then producing an income of 122*l.* 4*s.* 7½*d.* per annum, of which endowment he made the Company of Mercers trustees. The gross average income of St. Paul's School is now about 5300*l.* per annum. (Carlisle's *Grammar Schools*, vol. ii. p. 94.) To further his scheme of retiring, Colet built for himself a handsome house near the royal palace of Richmond in Surrey, in which he intended to reside, but having been seized by the sweating-sickness twice, and relapsing into it a third time, a consumption ensued, which proved fatal, Sept. 16, 1519, in his fifty-third year. He was buried in St. Paul's choir, with an humble monument which he had himself prepared some years before, bearing simply his name. Another monument was afterwards set up for him by the Mercer's Company, of a handsomer description; but it was destroyed in the fire of 1666. It had previously been engraved for Dugdale's 'History of St. Paul's.' Dean Colet's works were, 1. 'Oratio ad Clerum in Convocatione,' anno 1511; reprinted by Dr. Samuel Knight, in the appendix to his Life of Colet, with an old English translation of it, supposed to have been done by the author himself. 2. 'The construction of the Eight Parts of Speech, entitled Absolutissimus de octo Orationis partium constructione Libellus,' 8vo. Antw. 1530. 3. 'Rudimenta Grammatices,' for the use of his school, commonly called 'Paul's Accidence,' 8vo. 1539. 4. 'Daily Devotions;' said not to be all of his composition. 5. 'Monition to a godly Life,' 8vo. 1534, &c. Many of his letters are printed in Erasmus's Epistles, and five, with one from Erasmus, in the appendix to Knight's Life. The original Statutes of St. Paul's School, signed by Dean Colet, were, some years ago, accidentally picked up at a bookseller's, by the late Mr. Hamper of Birmingham, and by him presented to the British Museum. (Knight's *Life of Dr. John Colet*, 8vo. Lond. 1724; Wood's *Athenæ Oxon.*; Chalmers's *Biogr. Dict.*, vol. x., pp. 31-36.)

COLIBRI. [HUMMING BIRDS.]

COLIC, (from κῶλον, *colon*,) *dolor colicus*, called by Sydenham and the old English writers the dry belly-ache; a disease attended with severe pain of the bowels, remitting and recurring at intervals, with constipation, and without fever. The seat of this malady is conceived to be chiefly, if not entirely, in that portion of the large intestines called the colon, and hence its name. It arises from a great variety of causes, and assumes a corresponding variety of forms, many of which have received distinct names; but pain and constipation of the bowels, with the absence of fever, are common to them all; and this concurrence of symptoms is essential to the medical notion of colic.

The pain in colic often most distinctly follows the course of the colon, while the morbid distension and contraction of the bowel (for these two morbid states alternate with each other, and attack successively different portions of the intestine) often become visible to the eye. The colon receives all that portion of the food which is not converted into chyle, together with all those portions of the pancreatic, biliary, and intestinal secretions, which do not form component parts of the chyle. Consequently it has a considerable mass of matter to carry downwards and convey out of the system. It is provided with muscular fibres, very much larger than those which belong to the small intestines. These fibres form three large bands, which are placed in a longitudinal direction along the intestine, and which produce the effect of dividing the inner surface of the colon into folds, so disposed as to form little distinct apartments called cells. In these cells the feculent matter, which should be slowly but progressively carried downwards, is sometimes collected and closely impacted, so that when at length rejected it has the form of those cells constituting hard rounded balls, termed *scybalæ*. The natural stimulus to the muscular fibres of the colon is the resinous portion of the bile [BILE], together with the non-nutrient portion of the aliment. It is easy then to conceive how a loss or diminution of the contractile power of these fibres may occasion the constipation incident to colic, attended with the retention of the feculent matter in the cells of the colon; how a suppression or an altered condition of the bile may contribute to the same effect; and how an acrid quality of the bile and of the non-nutrient portion of the aliment may produce the irritation and pain incident to colic. The colon then, both from its structure and function, it is obvious must be peculiarly predisposed to such an affection as that to which, from the frequency with which it is the subject of the malady, it has given a name. It is perhaps desirable that the term colic should be restricted to the designation of a disease of a definite character, seated in the colon; and some medical writers do so limit the use of the term, though others give it a more extended signification, and with less propriety include under it diseases which do not arise primarily in the colon, but in some neighbouring organ, the colon being only secondarily and sympathetically affected.

Colic, properly so called, is attended with severe griping pains in the bowels, which often follow very accurately the course of the colon; sometimes having their seat in one portion of it and sometimes in another. These pains remit for a time, affording intervals of ease; but they soon return with increased violence. They are often relieved by pressure, a character by which they are distinguished from pain occasioned by inflammation, the latter being always increased by pressure. The pain is usually attended with a greater or less degree of flatulence. The flatus sometimes collects to such an extent as to occasion a prodigious dilatation of the bowels, greatly increasing the pain. When the digestive process is perfectly natural, it is always attended with the evolution of some portion of gas; in disordered states of digestion, the quantity of gas is often very much increased. But in colic the quantity generated is sometimes greater than can possibly be derived from this source; there would appear to be an actual generation of a gaseous fluid, probably from the blood. While one portion of the intestine is thus preternaturally distended, another portion is in a state of preternatural contraction, from the irregular spasmodic action of the muscular fibres of the colon, excited by the irritating cause—whatever it may be—which produces the disease. These irregular spasmodic contractions of the colon are always present when this disease is severe, and are intensely painful. The constipation, which is so constant as to be a diagnostic character of the malady, is often long continued and obstinate, and the consequent accumulation of feculent matter is very great. To the preceding train of symptoms is very frequently superadded vomiting, which is often urgent and most distressing; and in cases of the greatest severity, the action of the whole intestinal tube above the seat of the disease is inverted, and the fæces are mixed with the matter vomited. Occasionally there is hiccough, and very often the griping pains are attended with loud rumbling noises in the interior of the intestines.

It is unnecessary in this place to enter into the details of the varieties of this malady to which physicians have assigned distinct names, since these varieties are merely modifications of the same disease produced by different causes. The preceding account will be sufficient to give to the general reader a distinct conception of the nature of the malady, and of the causes which produce it; and it is only necessary to observe respecting the treatment, that the two great principles on which the cure depends are the complete evacuation of the intestine, and the strict regulation of the diet. It is indispensable that the evacuation of the intestine of its accumulated and irritating contents should be complete, and this is best affected by an alternation of mild and unirritating aperients, with opiates. After the intestine has been fully relieved of its load, it is necessary to persist in a course of mild aperients for a considerable time; because the bowel long remains in an irritable state, and very slight causes are apt to occasion a relapse. For the same reason only the most bland and unirritating substances should be taken as food; all acid and acrid matters in the solid and all stimulating matters in the fluid aliment should be most carefully avoided.

COLIGNY, GASPARD DE, born in February, 1516, was the son of Gaspard de Coligny, lord of Châtillon-sur-Loing and marshal of France, and of Louise de Montmorency, sister to the famous duke and constable of that name. Coligny served in Italy under Francis I., and was present at the battle of Cerisoles. Henry II. made him Colonel-General of infantry, and afterwards, in 1552, Admiral of France. In the latter capacity he sent a colony to Brazil, which however was soon after driven away by the Portuguese. Coligny himself continued to serve in the army by land. He defended St. Quentin against Philip II., and was made prisoner at the surrender of the place. Having embraced the reformed religion, he became, with Louis prince of Condé, one of the great leaders of the Protestant party against Catherine de' Medici and the Guises, during the reign of Charles IX. Coligny was much respected by his party: he was prudent in his plans and cool in danger; defeat did not dishearten him, and he rose again after it as formidable as ever. After the loss of the battle of Dreux, in which Condé was taken prisoner, Coligny saved the remains of his army. The following year peace was made, but in 1567 the civil and religious war broke out again, and the battle of St. Denis was fought, in which the old Constable Montmorency, who commanded the royal or Catholic army, was killed. A short truce followed, but hostilities broke out again in 1569, when the battle of Jarnac was fought, in which the prince of Condé was killed. Coligny again took the command and saved his army, which was soon after joined by the prince of Béarn (afterwards Henry IV.), then sixteen years of age, and Henry the son of Condé, who was but seventeen. The prince of Béarn was declared the head of the Protestants, but Coligny exercised all the functions of leader and commander. On the 3rd of October, 1569, Coligny lost the battle of Moncontour, against the duke of Anjou (afterwards Henry III.). Still Coligny continued the war south of the Loire, gained several advantages, and at last a peace was concluded at St. Germain in August, 1570, which was called 'la paix boiteuse et mal assise,' because it was concluded by the Sieur de Biron, who was lame, and by De Mesmes, lord of Malassise. The peace however fully deserved its nickname, by the spirit in which it was concluded by the Court. The leaders of the Protestants, and Coligny among the rest, entertained strong suspicions on the subject, but they were lulled into security by the apparent frankness of Charles IX., and the approaching marriage of the prince of Béarn with the Princess Margaret, the king's sister. Coligny came to Court, and was well received, but on the 22nd of August, 1572, he was shot at in the street by an attendant of the duke of Guise. The wounds however did not prove dangerous. The attempt was made at the instigation of the duchess of Nemours, whose first husband, Francis duke of Guise, had been assassinated by a Huguenot fanatic at the siege of Orléans in 1563, when Coligny was unjustly suspected of having directed the blow. On the 24th of August, 1572, two days after the attempt upon Coligny's life, the massacre of 'la Sainte Barthélemi' took place. [Bartholomew, Massacre of.] The duke of Guise himself led the murderers to the house of the admiral, but remained in the court below, while Besme, one of his servants, went up followed by others. They found Coligny seated in an armchair; 'Young man,' said he to Besme, 'you ought to respect my grey hairs; but do what you will, you can but shorten my life by a few days.' They stabbed him in several places, and threw him, still breathing, out of window into the court, where he fell at the feet of the duke of Guise. His body was left exposed to the fury of the populace, and at last was hung by the feet to a gibbet. His head was cut off and sent to Catherine de' Medici. Montmorency, cousin to the admiral, had his body secretly buried in the vaults of the château of Chantilly, where it remained in a leaden coffin till 1786, when Montesquieu asked for the remains of Coligny from the duke of Luxembourg, lord of Châtillon, and transferred them to his own estate of Maupertuis, where he raised a sepulchral chapel and a monument to the memory of the admiral. After the revolution the monument was transferred to the Musée des Monumens Français, and a Latin inscription was placed upon it by M. Marron, the head of the Protestant consistory at Paris. (Coligny's biography in the *Hommes Illustres de France*, and *Dictionnaire Universel Historique*, art. 'Coligny.')

COLISE'UM, properly Colosseum. [Amphitheatre.]

CO'LIUS. [Fringillidæ.]

COLLATERALS. [Consanguinity.]

COLLATION. [Benefice.]

COLLE'GIUM, or CONLE'GIUM, from the word 'colligo,' 'to collect or bring together,' literally signifies any association or body of men. The word Corpus was also used in the same sense, and those who were members of a collegium or corpus were hence called corporati. The word Universitas was sometimes used as equivalent to Collegium or Corpus, but it had also the more general signification of 'community,' or 'collective body of citizens.' In the Roman polity collegium signified any association of persons such as the law allowed, and which was confirmed by special enactment or by a senatus consultum, or an imperial constitution, in which case it was called Collegium Legitimum. A collegium necessarily consisted of three persons at least. (*Dig.* 50, tit. 16, l. 85.)

In general, any association or collegium, unless it had the sanction of a senatus consultum, or of the emperor, was illegal (illicitum); but when dissolved, the members were allowed to divide the property of the association according to their respective shares. The members of a collegium were called sodales: the terms and object of their union or association might be any that were not illegal.

A great variety of collegia (many of them like our companies) existed at Rome and in the empire, as we see by antient writings and inscriptions, such as the Collegia Fabrorum, Pistorum, Pontificum, Fratrum Arvalium, Virorum Epulonum, Augurum, &c. Some of these, such as the colleges of Pontifices and Augurs, were of a religious character. These collegia possessed property as a corporate body; and in the time of the emperor, M. Antoninus, if they were collegia legitima, they could take a legacy or bequest (*Dig.* 40, tit. 5, l. 20) in their corporate capacity. Collegia were allowed, as a matter of course, to have a common chest, and an actor, syndicus or attorney, to look after their rights and interests, and appear on their behalf. (*Dig.* 3, tit. 4, l. 1.) The maxims, that what was due to a university was not due to the individual members, and that the debts of universities were not the debts of the individual members, and that even though all the members were changed, the university still existed, comprehend the essential notion of a corporation as now understood. In most cases the members probably filled up vacancies in their own body; as to the mode of election in the college of Augurs, see Augurs.

In England a College is an eleemosynary lay corporation, of the same kind as an hospital, existing as a corporate body either by prescription or by the grant of the king. It is not necessarily a place of learning. An hospital also is not necessarily a mere charitable endowment, but is sometimes a place of learning, as Christ's Hospital, London. Its particular form and constitution depend on the terms of the foundation. A college consists of a head, called by the various names of provost (præpositus), master, rector, principal or warden, and of a body of fellows (socii), and generally of scholars also, besides various officers or servants, according to the peculiar nature of the foundation. A college is wholly subject to the laws, statutes, and ordinances which the founder makes, and to the visitor whom he appoints, and to no others. All elections, and the general management of a college, must be in conformity with such statutes or rules. If a college does not exceed its jurisdiction, the king's courts have no cognizance, and expulsion of a member is entirely within its jurisdiction. If there is no special visitor appointed by the founder, the right of visitation, in default of the heirs of the founder, devolves upon the king, who exercises it by the great seal. When the king is founder, his successors are the visitors.

The general power of a visitor is to judge according to the statutes of a college, to expel and deprive for just reason, and to hear appeals. His precise powers are determined by the founder's statutes, and if there are any exceptions to his power, the jurisdiction in such excepted cases devolves on the king. Certain times are generally named in the statutes for visitation, but the visitor may visit whenever he is called in, it being incident to his office to hear complaints. So long as a visitor keeps within his jurisdiction his acts cannot be controlled, and there is no appeal from him, as was decided in the well-known case of Philips *v.* Bury, or the case of Exeter College, Oxford. (Show. P. C. 35). The visitors are not bound to any particular forms of proceeding, and, in general, want of jurisdiction is the only ground on which they are liable to prohibition. If a visitor's power is not limited or defined, he must use his best discretion. If a power to interpret the statutes is given to any person, as to the bishop of the diocese, this will constitute him and his successors visitors. The heirs of a founder cannot alter the statutes, unless such a power is expressly reserved; and it appears, that where the king is founder, his successors cannot alter statutes without the consent of the college, unless such a power is reserved. But as to the power to alter statutes, it must be observed, that in the case of the crown at least, it has not unfrequently been done, though such a power might now possibly be disputed, unless expressly reserved to the founder and his heirs by his original statutes.

Whenever a visitor is appointed, the Court of Chancery never interferes with the internal management of a college; but this court exercises jurisdiction on all matters pertaining to the management of the funds, considering that as to the funds of a college, those who possess the legal estate are in the situation of trustees. If governors, or persons called visitors, have the legal estate, and are intrusted with the rents and profits, the Court of Chancery will make them account. In colleges, when a new foundation is engrafted on the old one, it becomes part of the old one, and subject to the same visitorial authority, unless new statutes are given with the new foundation.

The validity of all elections in colleges must be determined by the words of the founder's statutes or rules. In the disputes that have arisen on elections, the point has generally been, whether the master's concurrence is necessary, or whether a bare majority of the electors, of which electors the master is one, is sufficient. In Catharine Hall, Cambridge, fellows must be elected 'communi omnium consensu aut saltem ex consensu magistri, et majoris partis communitatis;' and it was held by Lord Eldon, upon these words and another clause which follows, that no election was valid in which the master did not concur.

The statutes of Clare Hall, Cambridge, require 'that the election of a fellow shall be by the master and the major part of the fellows present'; and here it was held (A.D. 1788) that a valid election might be made without the concurrence of the master. But this interpretation is obviously wrong, and is referred to with disapprobation in the recent case of Queen's College, Cambridge, 5 Russell.

Colleges (13 Eliz., c. 10), cannot grant leases of their land beyond 21 years, or three lives; and in such leases the accustomed yearly rent, or more, must be reserved, payable yearly during the term. By 18 Eliz., c. 6, in all leases made by colleges in the universities, and by the colleges of Winchester and Eton, one-third of the whole rent must be reserved in corn. The Mortmain Act of 9 Geo. II., c. 36, which has put considerable obstacles in the way of gifts of land or money to be laid out in land in England, for charitable purposes, does not extend to the two universities of Oxford and Cambridge, or to colleges in the two universities, nor to gifts in favour of the scholars of Eton, Winchester, and Westminster. This statute contained a restriction as to the number of advowsons which a college in either of the universities was allowed to hold; but this restriction was removed by 45 Geo. III., c. 101, having been found, as the preamble to this statute sets forth, injurious to learning. These colleges can therefore now purchase and hold as many advowsons as they please.

A collegiate church is a church that has a college or chapter of canons, but no bishop, and yet is under the authority of a bishop. The canonists require three canons at least to constitute a collegiate church, because three, according to the Roman law, were required to make a college. These collegiate churches are sometimes simply called colleges. In the case of Manchester College, a mandamus was directed to the bishop of Chester, as warden of Manchester College, to admit a chaplain. The bishop happened also to be visitor of the college. It was held by the King's Bench, that in the case of a spiritual corporation the jurisdiction was in that court, unless there was an express visitor appointed, and the court interposed in the present case because there was no separate visitorial power then existing, owing to the union of the wardenship and visitorship in the same person. This case was afterwards provided for by an express Act, 2 Geo. II., c. 29.

As to the relation between the English universities and the colleges within their limits, see University and Cambridge and Oxford. The nature of a college in the English universities, considered simply in itself, will be best understood by referring to the particular accounts of colleges in this work, as Brasenoze, All Souls, Balliol, &c.

The statutes of all the old colleges in England are in Latin; and, indeed, with the exception of some comparatively modern endowments, probably all college statutes are in Latin. Those of Eton College, of Trinity College, Cambridge, and of St. John's College, Cambridge, which may serve as specimens of the statutes of such foundations, are printed in the Education Reports of the House of Commons, 1818.

Meiners (*Geschichte der Enstehung und Entwickelung der Hohen Schullen*, &c., Göttingen, 1802, vol. i.) has given an interesting chapter on the origin of colleges in universities. The colleges in the University of Paris were the first institutions of the kind in Europe, though it is a mistake to suppose them older than the university itself.

The terms college and university have been often confounded in modern times, and indeed are now sometimes used indiscriminately. Some of the incorporated places of learning in the United States, which confer degrees, are called universities, and some are called colleges, though there is in fact no distinction between the two. Some of these institutions called colleges contain the schools or departments of arts, law, medicine, and theology; and some that are called universities contain only those of arts, law, and medicine. Some of these colleges are more limited as to the objects of instruction, but still confer degrees. If we look to the origin of colleges and their connexion with universities, it will be evident that the indiscriminate use of these terms is incorrect, and tends to lead to confusion. When an incorporated college, such as the College of Surgeons in London, is empowered to confer a degree or title after examination of candidates in a single department, some other name would be more appropriate. The word Academia, which is the most modern of all the terms applied to places of higher instruction, has been most usually applied to endowed corporate bodies which have for their object the improvement of some particular science or some particular branch of knowledge, in some cases with the power to confer degrees in such particular science, &c., and sometimes without this power. Yet the terms academia and university have also often been used, and now are used indiscriminately. (Meiners, vol. iv., *On the Different Names of High Schools*.)

The history of the Scotch universities shows that the terms college and university were, both at the time of the foundation of these institutions and subsequently also, used with little discrimination; and this carelessness in the application of the terms has led to anomalies in their constitution, and no little difficulty in comprehending the history and actual constitution of these bodies. (See the *Report of the Royal Commission of Inquiry into the State of the Scotch Universities*, printed 1831; and Malden's *Origin of Universities*, London, 1835.)

In France, the term college signifies a school, though the constitution of a French college is very different from that of our grammar-schools. It comes nearest, perhaps, to a German gymnasium. Of these colleges there are about 320, every large town having one of them. They are maintained by the towns, their heads and professors being paid out of the revenues of the communes. They are all under the superintendence of the University of France. There are also about forty royal colleges, in which the directors (*administrateurs*) and professors are paid by the state. The College Royal of France, founded by Francis I., has above twenty professors, who lecture on the various sciences and the oriental languages. (See *Journal of Education*, No. III 'On the State of Education in France.')

COLLIER, JEREMY, was born on the 23rd of September, 1650, at Stow Qui in Cambridgeshire. He was educated under his father, who was master of the free-school of Ipswich. In 1669 he was admitted of Caius College, Cambridge, and in 1676 took the degree of M.A. He resided some time as chaplain with the countess dowager of Dorset, and then received the small rectory of Ampton, in Suffolk. In 1685 he resigned this living and came to London, when he was soon appointed lecturer of Gray's Inn. At the revolution of 1688 he put himself in opposition to the government and the church as established under William III., and engaged in a hot controversy with Burnet, afterwards bishop of Salisbury. One of his publications, 'The Desertion Discussed, in a Letter to a Country Gentleman,' (4to. 1688) gave great offence to the new government, and Collier was sent a close prisoner to Newgate, where he remained some months, and whence he was, at last, discharged without ever being brought to trial. This persecution did not cool his zeal: during the four following years he published a number of works, which were all of a political and controversial nature. Towards the end of 1692 Collier, with Newton, who was also a non-juring clergyman, was arrested at a solitary place on the Kentish coast, whither he was supposed to have gone for the purpose of communicating with the partisans of the house of Stuart on the other side of the water. After a short examination before the earl of Nottingham, secretary of state, he was committed to the Gate-house. There was no evidence against him; but in consequence of his questioning the legality of the courts, and refusing bail, he suffered a short imprisonment in the King's Bench.

In the course of 1692 and 1693 he published six more works, all hostile to government. In 1696 he was prosecuted for giving church absolution to Sir John Friend and Sir William Perkins, who were convicted of being accessories in the plot to assassinate King William. Collier absconded and was outlawed. The outlawry was never revoked, but the energetic divine, after the first rigour was abated, seems to have cared little for it. He lived in London or its suburbs till his death, supporting himself by his literary labours. In the course of the very year in which he was outlawed he put forth five political works. The next year he published the 1st volume of his 'Essays upon several Moral Subjects,' adding a 2nd vol. in 1705, and a 3rd in 1709. These essays were much admired at the time. It was, however, in 1698 that he produced the work by which he is now best known: 'A Short View of the Immorality and Profaneness of the English Stage, together with the Sense of Antiquity upon this Argument,' 1 vol. 8vo. The 'Short View' was almost as severe upon theatres and theatrical writers as Prynne's famous 'Histrio-Mastix,' published about 65 years before. It led to a controversy with Congreve and Vanbrugh, in which many sheets were printed on both sides, many hard names exchanged, and in which Collier, to whom contest was a delight, is thought to have had the better of his adversaries. After three other defences of his 'View,' he published, in 1703, 'Mr. Collier's Dissuasive from the Play-house, in a Letter to a Person of Quality, occasioned by the late calamity of the Tempest.' This literary combat lasted ten whole years; but Collier lived to see the English stage become much more decent than it had been—an improvement to which he had doubtlessly contributed.

Between the years 1701 and 1721 he translated and published Moreri's great 'Historical Dictionary,' and wrote and published 'The Ecclesiastical History of Great Britain,' in two huge folio volumes. The history was attacked by Bishop Burnet and others, to whom Collier replied with his usual vigour. He was the author of a few other religious and controversial papers. He died on the 26th of April, 1726, in the 76th year of his age, and was buried in the church-yard of St. Pancras, London.

COLLIMATION, LINE OF, the line of sight in any astronomical or geodesical instrument. [Circle.] Where a telescope is used, this name is given to the line joining the centre of the object-glass and the intersection of the fine wires or spiderwebs in its focus, this being the direction of any object which is there seen bisected by the observer.

COLLIMATION, ERROR OF. In most instruments the line of sight is supposed to have a certain relation to other parts. Thus in a transit telescope it ought to be perpendicular to the horizontal axis, in a circle or quadrant it should be in a horizontal or vertical direction when the reading of the limb is 0° or 90°. When this is not the case, the difference between the existing and required positions is called the *error of collimation*, which must be carefully ascertained, and be corrected or allowed for, or eliminated in the mode of conducting the observations. This will be particularly explained as each instrument comes under our notice. Many readers will have a general notion of the error of collimation from the mode in which a workman tries the truth of his square, or of the mason's level, which in principle is nearly allied to the methods of astronomers. When the telescope was originally applied to astronomical instruments, the mystery of ascertaining the true direction of a line which could not be mechanically examined, presented considerable difficulties to some observers. Hevelius of Danzig never could be induced to apply telescopic sights to his sextants or quadrants, and in consequence of this prejudice much of the labour of his long and active life was completely wasted.

COLLIMATOR, the name given by Captain Kater to his contrivance for determining the error of collimation in any principal instrument, without the reversal of the instrument itself. This reversal troublesome in all large instruments, and in mural circles and quadrants is forbidden by their construction. We shall give a sketch of Captain Kater's collimators and those antecedent to his invention, and a drawing and description of a *level* collimator, which on the whole we think best suited for common use. Where the adjustments, &c., mentioned are not described, the reader will find them in the article Circle.

On referring to the description of each instrument, it will be seen that the determination of the error of collimation requires—1. a well-defined object, of which the direction remains unchanged; 2. a reversal of the instrument, similar to that of the mason's level; 3. for angular instruments, a power of determining the relation of the direction of that object to a vertical line. Now a near object cannot be seen on the wires of a telescope when they are in the focus of the object-glass, and a distant object is very seldom sufficiently steady or sharply defined. This want may be supplied by a second telescope, having its axis parallel to the axis of the telescope under examination and nearly in the same right line, which has cross wires in its focus; the object-glasses being towards each other. As parallel rays falling on an object-glass converge to the focus, so rays diverging from the focus become parallel after refraction at the object-glass, and emerge as if they came from a real object at an infinite distance; hence the cross wires in the supplementary or collimating telescope will be seen distinctly in the *direction* of the line joining the cross and the centre of the object-glass, in whatever part of the cylinder of issuing rays the eye may be placed. Great care is requisite in adjusting the wires of the collimating telescope exactly to focus, especially if a short telescope be used; but the axes of the two telescopes need only be approximately in a right line.

In many of the private observatories in England, a metal plate with sharp lines or dots engraved upon it, is firmly secured to an outside stone and viewed through a lens fixed in the wall of the observatory, the distance between the lens and the mark being equal to the focal distance of the lens. It is evident that such a mark may be used for determining the error of collimation in altitude of a reversible circle, and in all cases where merely a distinct and distant object is required. If the position of the mark be permanent, and the focal length of the lens be considerable, this may be advantageously used as a *meridian mark* [Transit]; but then the lens should have a separate support within the observatory, and the position of the mark should be jealously watched and verified. Dr. Rittenhouse first made use of this substitute for a distant mark (*American Philosophical Transactions*, vol. ii. p. 181); and we believe Dr. Maskelyne at one time used an adaptation of the same principle, viz., a cap with a lens of long focus, slipping over the object end of his transit telescope, to view the south meridian mark at Greenwich, which was too near the observatory to be seen distinctly

The collimating telescope and its cross wires are thus made to supply the want of a distinct, distant, and immovable object. In the *Astronomische Nachrichten*, No. 43, Professor Gauss, after enunciating the optical property above mentioned, used it for measuring the intervals between the wires of a transit telescope by a theodolet, which viewed them through the object-glass of the transit. In No. 61 of the same work, Professor Bessel applied the same principle to a still more important purpose, that of determining the horizontal flexure of the telescope of his meridian circle. After taking out the object-glass and eye-piece of this instrument (or the instrument might have been raised out of the way), he placed two collimating telescopes, one to the north and the other to the south of the circle, looking into each other, and nearly in the horizontal line which passed through the centre of his instrument. These he adjusted to have their cross wires apparently upon each other, when the two object-glasses and the two crosses are evidently all in the same right line. The object-glass and eye-piece were then replaced in the circle telescope, and the angle between the two crosses of the collimator measured, which would have been exactly 180°, without flexure; hence the difference from 180° was the double horizontal flexure of the circle telescope. Bessel further remarks, that a vertical telescope turning freely round in its collars, and having a cross level attached, might be used for determining the true zenith point of any instrument, without reversing the latter. The date of this publication is July, 1824.

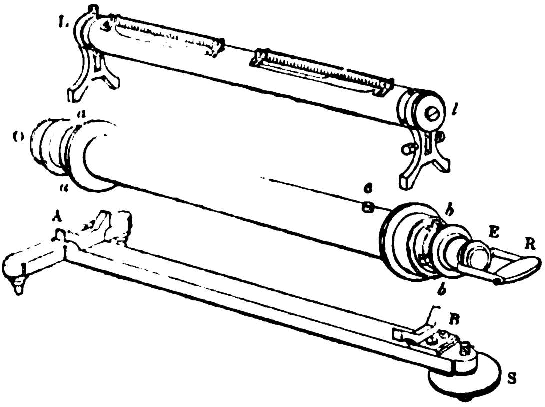
Captain Kater, who had not heard of either of these memoirs, gave, in the *Philosophical Transactions*, 1825, p. 147, a description and figure of a *horizontal floating* collimator. This is a telescope laid horizontally upon a block of cast iron, which floats in a vessel filled with mercury. This collimator was designed for determining the *zenith point* of mural and other irreversible circles. The cross of the collimating telescope is observed by the circle telescope in one direction, suppose to the north, and the divisions read off. The trough of mercury with the collimator floating in it, is then transported to the south of the circle, the cross again bisected, and the divisions read off as before. If the angle which the line of sight of the collimating telescope makes with the horizon be supposed to be unchanged by this change of place, it is clear that half way between the means of the two sets of readings is the reading corresponding to the vertical position of the circle telescope. Again, as the difference of the north and south mean readings would equal 180°, if the collimating telescope were truly horizontal, half the excess of this difference above 180°, or half the defect from 180°, will be the angle which the collimating telescope makes with the horizon. We believe however that, in addition to the trouble of moving such an apparatus, the permanence of the position of the collimating telescope could not be relied upon if at all disturbed.

In the *Philosophical Transactions*, 1828, p. 257, Captain Kater proposed a very much improved form of this in strument, which he called the *vertical* floating collimator. The iron float is here a ring swimming in an annular trough, and the telescope, which is placed vertically, has a clear view through the centre of the float and trough. This collimator may be placed below the instrument to be examined, when the collimating telescope will have its object-glass uppermost, or, as is most usual, above the instrument, when the collimating telescope looks downwards. A smooth rotatory motion upon rollers can be given to the annular trough, when it is evident the line of sight of the collimating telescope will either be and continue to be vertical (supposing the position of the float to be permanent), or will describe a conical surface of which the axis is vertical. Hence if the cross be bisected in two opposite positions of the collimator by the telescope of a circular instrument, the mean of the two readings will be the reading of the zenith of the instrument.

It will, generally speaking, be convenient to adjust the axis of the collimating telescope truly vertical. To do this, first observe the position of the cross by a circle or transit telescope, turn the collimator half round, and note the position again; then, by placing a small weight upon the float, bring the cross half way between the two observed positions. Turn the collimator a quarter round and perform the same adjustment for this and its reversed situation. The axis of the collimating telescope is now truly vertical. From some trials, which however we must admit were not made under favourable circumstances, we do not think the vertical floating collimator capable of giving results as accurate as may be obtained by other means; but it ought also to be stated that there is a good deal of difference of opinion among practical astronomers upon this point.

In the accompanying figure we have represented a more portable, and perhaps a more accurate instrument for determining the error of collimation, and also the position of the horizon, than either of the floating collimators.

The three parts of which this collimator consists have been separated from each other for easier comprehension. The telescope O E rests with its ground cylindrical collars, *a a*, *b b*, in the rectangular Y's, A, B of the stand. These collars should be truly cylindrical, and, if possible, exactly equal. There are cross wires which must first of all be placed correctly in the focus of the object-glass, when the screw *c* is to be tightened. To adjust the cross-wires, bring the intersection of the cross to bisect any distinct and immovable object (the wires of another telescope, for instance), turn the telescope half round in its Y's, and then, by releasing one of the four adjusting screws, (the heads of which are seen near *b b*,) and screwing up its antagonist, bring the cross *half way* back to coincidence, and complete the coincidence by screwing S. When this has been done satisfactorily, adjust the cross in the transverse direction by the other two screws, and it will then be found that the telescope can be turned round without any apparent change of place in the cross wires, that is, the line of sight is in the axis of the collars or parallel to the axis. The reflector R, which is merely to throw the light of the sky or a lamp upon the wires, may now be put on.



[Level Collimator, Troughton and Simms.]

The collimator being thus adjusted, is to be set to the north or south of the circle under examination, and at the same height as the centre of the telescope, when the axis [illegible] collars is to be made horizontal by the reversible level *L l*, and the foot screw S. When the cross of the collimator is bisected by the wires of the circle telescope, the telescope is horizontal, and the mean reading of the circle microscope is the reading of the *horizontal point*, which, if the circle reads altitudes, should be 0°, and if zenith distances, should be 90°. The difference from these values is the error of collimation. By setting the collimator to the other side of the instrument any error of flexure may be detected.

We have said that the cylindrical collars should be perfectly equal, but it is not easy to make them so. The difference is easily ascertained by reversing the telescope in its Y's, end for end, and again applying the level. Suppose the level to have shown perfect horizontality before reversing, and that afterwards the reading towards O exceeds that towards E, by m''. It will easily be seen that $\frac{m''}{4}$ must always be *subtracted* from the indications of the level towards O. It is equally evident, that if, after the above correction is made, the object end O appears too high by n'', that the true angle with the vertical is $90 + n''$, or that the reading of the circle should show n'' of depression. The different cases which may occur present no difficulty. If the collars are truly cylindrical and the level a delicate one, such a collimator should show the true horizontal point within 1″. The telescope should not be very small, not less than 12 inches.

It would scarcely be just not to notice under this head an instrument by Roemer, which has as much merit, as an invention, as any of these which we have described. It consists of two equal lenses fixed in a tube at a distance somewhat exceeding their focal length, with a system of wires in the focus of each, between the glasses. By applying the proper eye-piece at each end, the near wires, and consequently objects through the most distant object glass, are made visible. The two object-glasses and the crosses of the wires being all adjusted in the same straight line, it is evident that, on looking in at each end of the tube, objects 180° apart will be seen on the crosses. Roemer called this tube an *amphioptron*, or *reciprocal telescope*, and used it for the transit adjustment in collimation of his *rota meridiana*. (Horrebow, *Basis Astronomiæ*, p. 97.)

For further details, see Pearson's *Practical Astronomy*, vol. ii., p. 446, plate xxi.

COLLIN, KOLIN, or NEU-KOLIN, a town in the Bohemian circle of Kaurzim, situated on the Elbe. It lies in 49° 59′ N. lat., 15° 10′ E. long., and contains 420 houses and about 5800 inhabitants, among whom are numbers of Jews. Large quantities of garnets, topazes, and cornelians are found in the vicinity, and polished here. In the neighbourhood, between the castle of Chotzemitz and the village of Planian, general Daun, the commander of the Austrian army, gained the famous victory over Frederick the Great on the 18th of June, 1757.

Collin contains a haupt-schule, or grammar school, and a manufactory of potash and one of cottons; a monastery of Capuchins, a church and a town-hall, both in the Gothic style, and a castle with grounds and a botanical garden attached to it. The town is well built, surrounded by walls, and finely placed upon an elevated rock, beneath which the Elbe has a considerable fall.

COLLINGWOOD, CUTHBERT, ADMIRAL LORD, was born on the 26th of September, 1750, at Newcastle-upon-Tyne. At the age of eleven he was sent to sea, as a midshipman, under the care of Captain, afterwards Admiral Brathwaite, who was the son of his mother's sister, and who seems to have taken extraordinary pains in giving him nautical knowledge. After serving some years with this relation, he sailed with Admiral Roddam. In 1774, during the American war, he went to Boston with Admiral Graves, and, in 1775, was made a lieutenant by him, on the day of the battle of Bunker's Hill, when Collingwood, with a party of seamen, supplied the British army with what it required. In 1776 he took the command of the Hornet sloop, and soon after met, at Jamaica, with his favourite companion Horatio Nelson, who was then lieutenant of the Lowestoffe. Collingwood says, in one of his interesting letters: 'We had been long before in habits of great friendship, and it happened here, that as Admiral Sir P. Parker, the Commander-in-Chief, was the friend of both, whenever Nelson got a step in rank, I succeeded him: first in the Lowestoffe, then in the Badger, into which ship I was made commander in 1779, and afterwards in the Hinchinbroke, a 28-gun frigate, which made us both post-captains.'

Although Nelson, who was a younger man, always kept a remove a-head of him, and came in for a much larger share of fame or popularity, Collingwood never had a feeling of jealousy towards his friend, whose merits he was always the first to extol, and whom he loved to the last hour of his life. Nelson, on his part, seems to have had a greater affection for Collingwood than for any other officer in the service.

In 1780 Nelson was sent, in the Hinchinbroke, to the Spanish Main, with orders to pass into the South Sea, by a navigation of boats along the river San Juan, and the lakes Nicaragua and Leon—a physical impossibility which no skill or perseverance could surmount. Nelson caught the disease of the climate, and his life was with difficulty saved by sending him home to England. Collingwood, who succeeded him at the San Juan river, had many attacks: his hardy constitution resisted them all, and he survived the mass of his ship's company, having buried in four months 180 of the 200 men who composed it. Other ships suffered in the same proportion. In August, 1781, Collingwood was wrecked in the middle of a dreadful night in the Pelican, a small frigate which he then commanded, on the rocks of the Morant-keys in the West Indies, and saved his own and his crew's lives with great difficulty. His next appointment was to the Sampson 64. In 1783 he went to the West Indies in the Mediator, and remained with his friend Nelson on that station till the end of 1786. He then returned, after 25 years' uninterrupted service, to Northumberland, 'making,' as he says, 'my acquaintance with my own family, to whom I had hitherto been, as it were, a stranger.' In 1790 he again went to the West Indies, but a quarrel with Spain being amicably arranged he soon returned, and seeing, as he says, no further hope of employment at sea, he 'went into the north and was married.' In 1793 the war with the French Republic called him away from his wife and two infant daughters, whom he most tenderly loved, though he was never after permitted to have much of their society. As captain of the Barfleur he bore a conspicuous part in Lord Howe's victory of the 1st of June, 1794. In 1797 he commanded, with his usual bravery and almost unrivalled nautical skill, the Excellent 74, in Jarvis's victory of the 14th of February, off Cape St. Vincent. In 1799 he was raised to the rank of rear-admiral. The peace of Amiens, for which he had long prayed, restored him to his wife and children for a few months in 1802, but the renewed war called him to sea in the Spring of 1803, and he never more returned to his happy home. This constant service made him frequently lament that he was hardly known to his own children; and the anxieties and wear and tear of it shortened his valuable life. Passing over many less brilliant but still very important services, Collingwood was second in command in the battle of Trafalgar, fought on the 21st of October, 1805. His ship, the Royal Sovereign, was the first to attack and break the enemies' line, and, upon Nelson's death, Collingwood finished the victory and continued in command of the fleet. He was now raised to the peerage. After a long and most wearying blockade of Cadiz, the Straits of Gibraltar and adjacent coasts, during which, for nearly three years, he hardly ever set foot on shore, and showed a degree of patience and conduct never surpassed, he sailed up the Mediterranean, where his position involved him in difficult political transactions, which he generally managed with ability. The letters to foreign princes and ministers, the despatches of this sailor who had been at sea from his childhood, are admirable even in point of style. Completely worn out in body, but with a spirit intent on his duties to the last, Collingwood died at sea on board the Ville de Paris, near Port Mahon, on the evening of the 7th of March, 1810. In command he was firm but mild—most considerate of the comfort and health of his men, averse to flogging and all violent and brutal exercises of authority; the sailors called him their father. As a scientific seaman and naval tactician he had few, if any equals, and in action his judgment was as cool as his courage was warm. His mind was enlightened to an astonishing degree, considering the circumstances of his life; he was liberal and kind-hearted, and all his private virtues were of the most amiable sort. His letters to his wife on the education of his daughters are full of good sense and feeling. (*A Selection from the Public and Private Correspondence of Vice-Admiral Lord Collingwood: interspersed with Memoirs of his Life.* By G. L. Newnham Collingwood, Esq., F.R.S., 2 vols. 8vo., second edit. Lond., 1828.)

COLLINS, JOHN, the son of a nonconformist clergyman, was born at Wood Eaton, in Oxfordshire, March 5, 1624. He was at first apprenticed to a bookseller at Oxford, but went abroad during the civil war, and served the Venetians at sea against the Turks. After the restoration he was made accountant to the excise office, which office was abolished before 1670. From that time he supported himself mostly by his skill in accounts. He died in London, November 10, 1683.

Collins was an early member of the Royal Society, and contributed some fair papers to its transactions. (Numbers 30, 46, 69, 159.) He also wrote several elementary works, which it is not now necessary to mention. His claims to remembrance are the intimate communication in which his attainments placed him with all men of science at home and abroad, from Newton downwards. The influence of his request and recommendation produced (as is asserted) Barrows's Lectures, his Archimedes and Apollonius, Branker's Translation of Rhonius, Kersey's Algebra, and Wallis's History of Algebra. The esteem in which Collins, a poor accountant, was held by men so much above him in external position, as Newton, Barrow, Wallis, &c., is honourable to all parties. The principal result however of their epistolary intercourse is the work on the invention of fluxions, published in 1712, under the title of 'Commercium Epistolicum,' &c., which will be noticed in a separate article. [COMMERCIUM EPISTOLICUM.] (See the *Biogr. Dict.*, which cites Birch; *Hist. Roy. Soc.*; and Wood, *Fasti Oxon.*)

COLLINS, ANTHONY, was born in 1676 at Heston, near Hounslow, in Middlesex. His father, Henry Collins, Esq., was an independent gentleman, with an income of 1800*l*. a year. After the usual preparatory studies at Eton, he went to King's College, Cambridge, and had for his tutor Francis Hare, afterwards bishop of Chichester. He then became a student of the Temple, and married a daughter of Sir Francis Child, lord mayor of London. During 1703 and 1704 he carried on a correspondence with Locke, who appears to have cherished a most enthusiastic friendship for him. Twenty-five letters of Locke to Collins are preserved in the 'Collection of Pieces by Locke, not contained in his works,' published by Des Maizeaux, 8vo., 1720. In one of these, dated October 29, 1703, Locke says to his friend, 'Your complaining of a great many defects is the highest recommendation I could desire to make me love and esteem you, and desire your friendship; and if I were setting out in the world, I should think it my greatest happiness to have such a companion as you, who have a true relish of truth—would in earnest seek it with me—from whom I might receive it undisguised, and to whom I might freely communicate what I thought true. Believe it, my good friend, to love truth for truth's sake is the principal part of human perfection in this world, and the source of all other virtues: and if I mistake not, you have as much of it as ever I met with in any body. What then is there wanting to make you a friend for any one to be proud of?' In one dated Oates, September 11, 1704, he says, 'Your soul is enriched with the most valuable qualities of human nature, truth and friendship: what a treasure have I then in such a friend with whom I can converse, and be enlightened about the highest speculations.' In one dated the 1st of the following October he says, 'My infirmities prevail so fast upon me, that unless you make haste hither I may lose the satisfaction of ever seeing again a man that I value in the first rank of those I leave behind me.' In a remarkable letter, dated August 23, 1704, and addressed 'For Anthony Collins, Esq., to be delivered after my decease,' Locke, after speaking of having left property to Collins, and the guardianship of a young friend, concludes with 'May you live long and happy—I know you loved me living, and will preserve my memory now I am dead. Adieu, I leave my best wishes with you.' In 1707 Collins published an essay concerning human reason as supporting human testimony. It was replied to by Bishop Gastrell. The same year he entered into a controversy with Dr. Samuel Clarke, in support of Dr. Dodwell's book against the natural immortality of the human soul. Five successive rejoinders were elicited. (*General Dict.*, fol., 1736; and *Biog. Brit.*) In 1709 he published 'Priest-craft in perfection, or a detection of the fraud of inserting and continuing this clause (the church hath power to decree rites and ceremonies, and authority in controversies of faith) in the 20th article.' It passed through three editions in the same year, and occasioned a very general and anxious inquiry. Numerous pamphlets, sermons, and books discussed the question. Two works especially were written against it with great labour, and were supplied with hints and materials from all quarters of the church: one, entitled 'A Vindication of the Church of England from Fraud and Forgery, by a Priest,' 8vo., 1710; the other, a long-delayed and elaborate essay on the Thirty-nine Articles, by Dr. Bennet, 8vo. To these Collins replied in his historical and critical essay on the Thirty-nine Articles, in 1724, proving (p. 277-278) that the clause has neither the authority of the convocation nor of the parliament. Collins's next work was entitled 'A Vindication of the Divine Attributes,' being remarks on a sermon of the archbishop of Dublin, which asserted the consistency of divine foreknowledge and predestination with human free-will. He went in 1711 to Holland, where he formed a friendly intercourse with Le Clerc, and other leading characters among the learned of that country. On returning to England he published, in 1713, his 'Discourse on Freethinking,' which excited much animadversion among the clergy. The most important of the replies which appeared was that by Dr. Bentley, entitled 'Remarks on the Discourse of Freethinking by Phileleutherus Lipsiensis,' which is remarkable as a display of learned sagacity, coarse wit, and the most intemperate abuse. The object of Collins is to show that, in all ages, the most intellectual and virtuous men have been freethinkers; that is, followers of philosophical reasoning, in disregard of established opinions. There are several French editions of this work. It was reprinted at the Hague, with some additions and corrections derived from Bentley's Remarks. On the continent it was answered by Crousaz, and several others. The 'Clergyman's Thanks to Phileleutherus,' 1713, is by Bishop Hare. Collins, on returning from a second residence in Holland, was made justice of the peace and deputy-lieutenant of the county of Essex, offices which he had previously held in Middlesex. In 1715 he published his 'Philosophical Inquiry concerning Liberty and Necessity,' which was reprinted in 1717 in 8vo., with corrections. It was translated into French, and is printed in the 'Recueil de Pièces sur la Philosophie,' &c., by Des Maizeaux, 2 vols. 12mo., 1720. Dr. Samuel Clarke replied to the necessarian doctrine of Collins, chiefly by insisting on its inexpediency, considered as destructive of moral responsibility.

In 1718 Collins was appointed treasurer of the county of Essex, an office which he performed with great fidelity. He married, in 1724, his second wife, the daughter of Sir Walter Wrottesley, Bart. In the same year he published his 'Grounds and Reasons of the Christian Religion,' in which his object is to show that Christianity is founded and dependent on Judaism; that the New Testament is based upon the Old, as the canon of Christians; that the apostles and writers of the former establish and prove their propositions from the latter; and that none of the passages they adduce are literally, but merely typically, and allegorically applicable, by the assumption of a double construction. This work created a great sensation in the church, and drew forth a great number of replies from some of the most eminent divines. In the final answer of Collins, 'Scheme of Literal Prophecy,' 1726, he enumerates five-and-thirty replies which appeared during the two first years after its publication. The artful way in which Collins availed himself of the theory of Whiston respecting the corruption of the present Hebrew text, so provoked that divine, that he petitioned Lord Chancellor King, though without success, to remove Mr. Collins from the commission of the peace. In 1727 Collins, in a long letter, replied to eight sermons of Dr. Rogers on the necessity of revelation and the truth of Christianity. He died in December, 1729, at his house in Harley Square, London, in consequence of being long afflicted with the stone. In his last moments he said, 'I have always endeavoured, to the best of my ability, to serve my God, my king, and my country, and I am certain I am going to that place which God has designed for those who love him, for the Catholic religion is to love God and to love man.' He was interred in Oxford Chapel, London. The long and elegant Latin epitaph on his monument there, is inserted in the 'General Dict.' and in the 'Biog. Brit.' All parties agree that the moral and social character of Collins was remarkably amiable. Temperance and benevolence were its prominent points. His integrity, energy, and impartiality in the exercise of his magisterial functions commanded the highest respect, and by all his conduct and writings he ardently endeavoured to promote the cause of civil and religious liberty. Collins, as a writer, is remarkable for the great shrewdness of his reasoning; and for still greater subtility in masking the real drift of his arguments with orthodox professions. His library, which was of great extent and extremely curious, was open to all men of letters, to whom he readily communicated whatever he knew, and even furnished his antagonists with books and arguments to refute his own writings. A catalogue of his books was published by the Rev. Dr. Sykes in 1730. (*General Dictionary*, *Biog. Brit.*; Hollis's *Memoirs.*)

COLLINS, WILLIAM, the son of a hatter at Chichester, was born December 25, 1720. He was educated at Winchester, from which he went to Queen's College, Oxford; but in about half a year he removed to Magdalen, on being elected a *demy*, or scholar, of that body. Soon after taking his bachelor's degree he quitted the university abruptly, about 1744, and repaired to London as a literary adventurer. He won the cordial regard of Johnson, then a needy labourer in the same vocation, who, in his 'Lives of the Poets,' has spoken of him with tenderness. He tells us that 'his appearance was decent and manly, his knowledge considerable, his views extensive, his conversation elegant, and his disposition cheerful. He designed many works, but his great fault was irresolution; or the frequent calls of immediate necessity broke his scheme, and suffered him to pursue no settled purpose.'

His Odes were published, on his own account, in 1746. They were not popular; and it is said that, disappointed at the slowness of the sale, he burnt the remaining copies with his own hands. He was relieved from his embarrassments by a legacy from an uncle of 2000*l.*; but worse evils than poverty overclouded the rest of his life: he sank gradually into a species of melancholy and intellectual languor, to relieve which, he resorted to intoxication. 'Those clouds which he perceived gathering on his intellect he endeavoured to disperse by travel, and passed into France; but found himself constrained to yield to his malady, and returned. He was for some time confined in a house of lunatics, and afterwards retired to the care of his sister at Chichester, where death, in 1756, came to his relief.' (*Lives of Poets.*)

Collins is inferior to no English lyric poet of the eighteenth century, except Gray. His Odes to 'Fear,' and the 'Passions,' afford the best specimens of his genius; and the well-known 'Dirge in Cymbeline' is admirable in a softer style. His poetical merits Dr. Johnson did not rightly appreciate. Mrs. Barbauld, in her edition of his works, has given a more favourable and juster character of them. 'He will be acknowledged to possess imagination, sweetness, bold and figurative language. His numbers dwell upon the ear, and easily fix themselves in the memory. His vein of sentiment is by turns tender and lofty, always tinged with a degree of melancholy, but not possessing any claim to originality. His originality consists in his manner, in the highly figurative garb in which he clothes abstract ideas, in the felicity of his expressions, and his skill in embodying ideal creations. As it was, he did not enjoy much of the public favour; but posterity has done him justice, and assigned him an honourable rank among those of our poets who are more distinguished by excellence than by bulk.

COLLISION (con, lædo.) The striking against each other of two bodies in motion. The mathematical laws of collision are usually treated under the word IMPACT in English treatises, and under the head *choc des corps* in French.

COLLURICINCLA. [LANIADÆ.]

COLLU'RIO. [LANIADÆ.]

COLMAN, GEORGE, commonly called 'the Elder,' was the son of Francis Colman, Esq., British resident at the court of the Grand Duke of Tuscany, by a sister of Anna-Maria Pulteney, Countess of Bath. He was born at Florence about 1733, and was educated at Westminster. He afterwards became a student of Christ Church, Oxford, and forming an acquaintance with Mr. Bonnel Thornton, published in conjunction with that gentleman, the perio dical paper called 'The Connoisseur.' Fixing on the law for a profession, he was entered at Lincoln's Inn, and duly called to the bar. In 1760 he produced his first dramatic piece, entitled 'Polly Honeycomb,' at Drury Lane with great success. This was followed in 1761 by the comedy of 'The Jealous Wife,' and in 1766 by that of 'The Clandestine Marriage,' written in conjunction with Mr. Garrick. In 1767 he united with Messrs. Harris, Rutherford, and Powell, in the purchase of Covent Garden Theatre, and became the acting manager, in which situation he continued seven years, when he sold his share to Mr. Leake. In 1777 he purchased the little theatre in the Haymarket of Mr. Foote. In 1785 Mr. Colman was seized with the palsy, and four years afterwards discovered symptoms of an alienation of mind, which gradually increasing terminated in a state of idiotism. He died at Paddington on the 14th of August, 1794, aged sixty-two. Mr. Colman, besides writing and adapting upwards of thirty dramatic pieces, was the author of a very spirited translation in blank verse of Terence, a translation of and commentary on Horace's Art of Poetry, and several fugitive pieces.

COLMAN, GEORGE, 'the Younger,' son of the preceding, was born October 21, 1762. His education was commenced at Mr. Fountain's academy in Marylebone, from whence he was removed to Westminster, and afterwards entered at Christ Church, Oxford. From thence he was sent by his father to King's College, Old Aberdeen, and on his return to London was entered of the Temple; but following the peculiar bent of his genius and the example of his father, he soon commenced writing for the stage. During the illness of Mr. Colman, Sen., he directed the Haymarket Theatre, and on the death of his father King George III. kindly transferred the patent to him. He married first Miss Morris, the sister of the present proprietor of the Haymarket, to whom he sold his interest in the theatre; and secondly, the popular actress Mrs. Gibbs. Mr. Colman, Jun., was appointed by George IV. Exon of the Yeoman Guard (an office which he afterwards by permission disposed of), and by his Grace the Duke of Montrose, then Lord Chamberlain, Examiner of Plays, which situation he held to the day of his death, Wednesday, October 26, 1836, having just completed his seventy-fourth year. Mr. Colman was the author of several excellent plays and farces: amongst the most popular are 'John Bull' (for which comedy he received the largest sum of money perhaps ever paid for any drama), 'The Poor Gentleman,' 'Heir at Law,' 'Inkle and Yarico,' 'Iron Chest,' 'Mountaineers,' 'Surrender of Calais,' 'Ways and Means,' 'Review,' 'Blue Beard,' 'X. Y. Z.,' and 'Love Laughs at Locksmiths.' He also wrote the well-known comic tales entitled 'Broad Grins,' 'Poetical Vagaries,' &c., and a variety of smaller poems. His last literary work was the publication of his own memoirs up to the time of his entering on the management of the Haymarket, in 2 vols., 8vo.

COLMAR, a town in France, capital of the department of Haut Rhin; on the left or west bank of the river Lauch, just above its junction with the Ill, and also on a branch or canal of the Fecht, another tributary of the Ill; 234 miles from Paris, in a direct line E. by S. or E.S.E., or 290 miles by the road through Châlons, Bar-le-duc, Nancy, &c. In 48° 5′ N. lat. and 7° 20′ E. long.

It has been thought by some antiquaries that Colmar was built of the ruins of the antient Argentuaria, or Argentovaria (*'Αργεντουάρια*, Ptolemy), near to which the Emperor Gratian defeated the Allemanni A.D. 378; but the position of Argentovaria was probably nearer the Rhine, between Markolsheim and Artzenheim. (D'Anville.) This town was much favoured by the Emperor Frederick II., who enlarged it. It was one of the imperial cities, and disputed with Ensisheim the precedency among the towns of the Upper Alsace. Having been ceded to France by the treaty of Munster in 1648, the king of France ordered the fortifications to be razed (A.D. 1673): Colmar is consequently an open town. Under the old government of France the inhabitants, though deprived of their antient municipal constitution, enjoyed several privileges; and the Reformed, who constitute half the population, had, as well as the Catholics, the free exercise of their religion. Colmar was formerly included in the diocese of Porentrui.

The town is beautifully situated in a plain near the foot of the Vosges. It is a handsome place; the streets are watered by small streams from the Lauch and the canal of the Fecht. The church of the Dominicans is the handsomest of its antient buildings. The prisons and the theatre are also worthy of notice. The inhabitants amounted, in 1832 to 15,131 for the town, or 15,442 for the whole commune They manufacture printed calicoes, tapes and ribands; there is a powder-mill near the city. Considerable trade is carried on in the agricultural produce of the district, wheat and other grain, and wine of good quality. The town is the seat of a *Cour Royale*, or supreme court of justice There is a college or high school, a société d'émulation, and a public library, one of the richest in France, containing above 60,000 volumes. The revenue of the town is considerable. Among the natives of Colmar may be mentioned Martin Schoen, the earliest engraver in metal, and Rewbel, one of the members of the Executive Directory of France.

The arrondissement of Colmar contained, in 1832, 189,589 inhabitants: it occupies the northern part of the department. It is the seat of an extensive cotton manufacture. The mountain streams which traverse it supply a moving power for machinery.

COLNBROOK. [BUCKINGHAMSHIRE.]

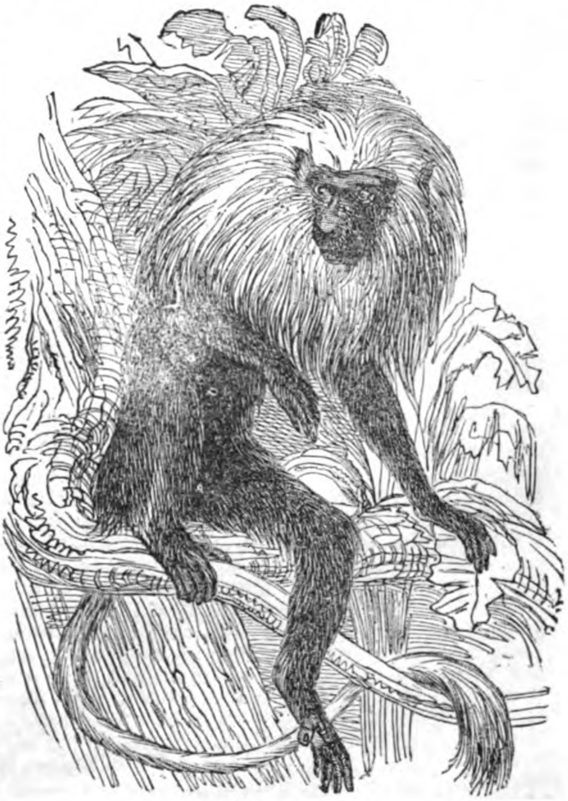
COLNE. [THAMES.]

CO'LOBUS (Zoology), a genus of Quadrumanous mammifers (Cheiropeds of Mr. Ogilby); established by Illiger and adopted by M. Geoffroy. The latter places the genus in the group of *Singes catarrhins*, or monkeys of the old continent; a group distinguished by having their nostrils separated by a very thin partition, and by possessing five molar teeth only on each side of the two jaws.

Generic character.—Facial angle from 40 to 45 degrees; muzzle short; face naked; body elongated and small; extremities slender; the anterior hands deprived of a thumb; the fingers rather short; the posterior thumb very distant from the fingers, and placed very much backwards; tail longer than the body, small, and tufted at the end; cheek-pouches and callosities on the buttocks.

The Colobi, which are supposed to be inhabitants of the Coast of Guinea, seem to be in the old world the representatives of Ateles, whose locality is South America. Example:—*Colobus polycomos*, Geoffroy.

This species, which is the *Simia polycomos* of Schreber, the *Simia comosa* of Shaw, the *Guenon à camail* of Buffon, and the *Full Bottom* of Pennant, is very handsome. The head and upper part of the body are covered with hair,



[Colobus polycomos.]

falling over the shoulders and forming a kind of hood and pelerine, from whence it derives the name given to it by Buffon, while the resemblance of this *chevelure* to a wig determined Pennant to give it the English name above recorded. This ornament is composed of floating hairs, which are yellow mingled with black; the face is brown, and the rest of the body is covered with very short close hair of a jet-black, a colour which sets off the snow-white tail, which is much longer than the body and not prehensile. In this last particular, in the possession of cheek-pouches, and in other characters, it differs from Ateles, while in some points, and especially in the absence of the thumb in the anterior hands, it resembles it much.

Locality, the forests of Sierra Leone, where the natives give it the name of 'the King of the Monkeys' (*Roi des Singes*), apparently, says Desmarest, on account of the beauty of its colours, and its 'camail,' which represents a sort of diadem. They attach great value to its fur, of which they make ornaments, and apply it to various purposes.

Besides M. Geoffroy's other species, *Colobus ferruginosus*, *Simia ferruginea* of Shaw, *Autre Guenon* of Buffon, the Bay Monkey of Pennant, which is by many considered to be only a variety of *Colobus polycomos*, the French zoologists mention another species, *Colobus Temminckii*, Kuhl, which is described by them as extremely scarce, and its locality unknown. The specimen belonging to M. Temminck came from Bullock's Museum, and together with many other rarities was suffered to leave this country when that fine collection was broken up, to the great regret of all English zoologists, and to the manifest advantage of foreign establishments.

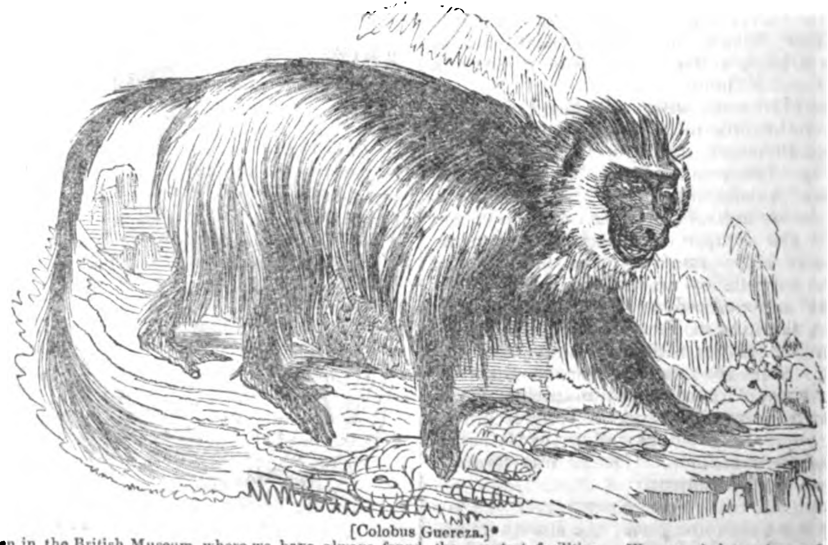
Such was the history of this curious genus; when in June, 1832, several imperfect skins of mammalia, recently obtained by Mr. Gould from Algoa Bay, were exhibited to the Zoological Society of London. One of these skins, that of a *monkey*, deficient as to the head and hands, was, Mr. Bennett remarked, evidently referrible to the *Colobus polycomos* of Illiger; the long milk-white tail strongly contrasting with the bright deep-black fur of the body, being fully sufficient to characterize it. On the upper part of the skin, above the shoulders, some nearly white hairs were intermingled with the black ones. The only discrepancy observable between the specimen and the description of the species given by Pennant was in the great length of the hairs of the body, the greater number of them being four or five inches long: this, it was stated, might be dependent on age or locality. Another skin, equally imperfect with the preceding, was declared to be that of the *Colobus ferrugineus* of Illiger, with the state of which, described by Mr. Kuhl under the name of *Colobus Temminckii*, the specimen agreed in every respect, except in the absence of any yellow tinge in the rufous fur covering the under surface of the body.

In July, 1835, Mr Ogilby exhibited to the same Society several rare and undescribed species of mammalia and birds, brought from the Gambia by Mr. Rendall. Among them were materials which, together with the specimens then lately brought from Abyssinia by Dr. Rüppell, gave Mr. Ogilby an opportunity of revising the natural history of the genus Colobus, six species of which he then recorded.

1. *Colobus polycomos*, Schreber, with the head and shoulders covered with long, coarse, flowing hair, of a dirty yellowish colour, mixed with black; body, arms, and legs of a fine glossy blackness, covered with short hair; tail of a snowy whiteness, with very long hair at the end, forming a tuft. (Pennant.) Locality, Sierra Leone.

2. *Colobus Ursinus*, Ogilby, 'with very long glossy black hair over the whole body and extremities, and a long snowy-white tail, tufted at the end;' described from two imperfect skins, without heads or hands, the same as those noticed by Mr. Bennett and above referred to. These skins, Mr. Ogilby remarks, were considered by Mr. Bennett as referrible to the *Colobus polycomos;* and the general colour of the body and tail, as well as a slight appearance of grizzled or gray hair about the neck, where the head had been cut off, would, at first sight, Mr. Ogilby allows, appear to justify Mr. Bennett's views; but the words of Pennant (the only original describer of the species) imply that the 'long dirty yellowish hair,' which he compares to a full-bottomed periwig, grows from the shoulders and neck, as well as the head, and expressly declare that the hair on the rest of the body, as well as on the legs, is short. Now, in the specimens at present under consideration, the very reverse of this is observable. The black hair of the shoulders, as already observed, has a partial mixture of silvery-white on the anterior face, just where the head has been cut off; but it is not longer than the hair upon the rest of the body and limbs, which is moreover five or six inches in length, and in texture and appearance not unlike that of the *Ursus labiatus*. The whole animal, in fact, resembles a small *bear*, and is covered with the same uniform, long, black, and glossy fur upon every part except the tail, which, at the root more particularly, is furnished with much shorter hair. Whether or not this species, like the *polycomos*, has the head of a different colour from the body, is a subject for further observation: the white or silvery hairs already mentioned as still remaining about the shoulders render it extremely probable that it has, but in no case can it form the striking contrast in length, nor present the long flowing mane or wig-like appearance ascribed to the animal observed by Pennant. Mr. Gould, who procured these skins for the Society, reported them as coming from Algoa Bay: we know enough of the zoology of that part of Africa to render this account extremely doubtful, and the probability is, either that Mr. Gould was misinformed, or that he may have mistaken Dalagoa Bay for Algoa, which, from the similarity of sound, might readily happen. If this conjecture should prove correct, it would follow that the *Colobus ursinus* was the analogue of the *Colobus polycomos*, on the opposite coast, and the conjecture receives further countenance from the fact of many other known species of mammals having such analogues in the same localities.

3. *Colobus Guereza*, Rüppell, with the head, face, neck,



[Colobus Guereza.]*

---

* From the specimen in the British Museum, where we have always found the greatest facilities. We are glad to observe that the collection of Mammalia has lately been increased nearly one-third.

back, limbs, and basal half of the tail, covered with short black hair; the temples, chin, throat, and a band over the eyes, white; the sides, flanks from the shoulders downwards, loins and buttocks, clothed with long flowing white, which hangs down on each side like a loose garment; the tip of the tail tufted with dirty-white. Locality, Abyssinia. There is a specimen, one of Dr. Rüppell's, in the British Museum.

4. *Colobus ferruginosus*, Geoffroy. Crown black; back of a deep bay colour; outside of the limbs black; cheeks, under part of the body, and legs, very bright bay; tail black. (Pennant's description.) Locality, Sierra Leone.

5. *Colobus fuliginosus*. Smoky-blue above, dirty yellowish-gray beneath; cheeks, throat, tail, and extremities, brick-red. (Ogilby.) Locality, the Gambia. Mr. Ogilby observes that the face is short, the head round, and the whole form and habit of the animal similar to those of the *Semnopitheci*. The teeth, he adds, are of the usual form and number, and *there are large and very distinct cheek-pouches*. 'I was the more particular,' says Mr. Ogilby, 'in making this last observation, because the organs in question had not been previously recorded as existing in the *Colobi*, and because M. Geoffroy St. Hilaire, in his valuable lectures, of which it is a matter of great regret that so small a portion has been given to the public, even doubts their existence.'

6. *Colobus Temminckii*, Kuhl, 'with the hands, face, and tail, purplish-red; rest of the members clear-red; belly reddish-yellow; head, neck, back, shoulders, and outer face of the thighs, black.' Habitation unknown: described from a specimen formerly in Bullock's Museum, and now in that of Leyden. Notwithstanding some slight discrepancies, Mr. Ogilby agrees with Mr. Bennett in referring to this species the two other skins of the Society's collection noticed by the latter and above alluded to. These skins, he observes, were procured at the same time, and most probably in the same locality, as those of *Colobus ursinus*, and are equally imperfect; and he further remarks, that if the conjecture already thrown out with regard to the derivation of these skins should turn out to be well founded, and if the animal described in his paper eventually proves to be identical in species with *Colobus Temminckii*, which he sees no just reason to doubt, it follows that the hitherto unascertained habitation of that species must be sought on the east coast of Africa. Mr. Ogilby adds, that Fischer, probably induced thereto by the authority of M. Temminck, has united the *Colobus Temminckii* with the *Colobus ferruginosus* or *Bay Monkey* of Pennant, but that there is no doubt as to the specific distinction of the two animals.

COLOCA'SIA, a kind of arum, the leaves and tubers of which, notwithstanding their acridity, are used as food by the natives of the south of Europe. It is cultivated in Portugal, Greece, and Egypt, and is supposed to have been the *Colocasium* of Virgil, the *Aron kurenäikon* of Galen, and the *Niliacum olus* of Martial.

COLOCYNTH. [CUCUMIS.]

COLOCZA (Kalocsa, Kalotscha), in the Hungarian circle of Pesth, is in a swampy plain, on a small arm of the left bank of the Danube, in 46° 32′ N. lat., and 19° 0′ E. long. It was known in the time of the Romans. It is the seat of an archbishop, and contains 1356 houses and about 6000 inhabitants. The most striking buildings are the palace of the archbishopric, which resembles a fortress, and has a library of 30,000 volumes, and the cathedral church of the Annunciation. To the archbishopric of Colocza is united the bishopric of Bacs, the metropolitan chapter of which has its seat also here. The town has an archiepiscopal lyceum, with a theological seminary; a Piarist college, which in 1825 contained 141 scholars; a gymnasium, and a Roman Catholic grammar school. The library contains the celebrated MS. called the 'Colocza Codex of Old German Poems,' supposed to have been written in the latter part of the fifteenth century. This valuable work is written and illuminated on beautiful parchment; contains 336 pages, comprises 15 poems, consisting of 54,000 verses, and is 4 inches thick, 11 high, and nearly 10 wide. The inhabitants are chiefly engaged in the breeding of horses and cattle, and in fishery.

COLOGNE, a government circle (Regierungs-Bezirk) of Rhenish Prussia, in the province of Juliers—Cleves-Berg, lies on the banks of the Rhine, which traverses it for twenty-eight miles from north to south, and divides it into the eastern and western portions. The southern, western, and eastern portions are mountainous, especially near Bonn; the northern is level, and contains but few elevations. Besides the Rhine, Cologne is watered by the Muhlenbach, Sieg, Strundesbach, Wipper, &c. The greatest length of the circle from east to west is about forty-six miles. It is bounded on the north by the circle of Düsseldorf, on the east by Arnsberg, on the south by Coblenz, and on the west by Aix-la-Chapelle, and occupies an area of about 1566 square miles. Of this surface about 517,000 acres are arable land, 31,800 gardens, 3000 vineyards, 77,000 meadows and pastures, 277,000 forest, 64,000 waste land, and 32,000 are occupied by roads and rivers. The circle is divided into 11 minor circles; viz., Bergheim, Bonn, Cologne, Enskirchen, Gummersbach, Mühlheim, Rheinbach, Sieg, Waldbroel, and Wipperfürth. It contains 17 towns, 4 market towns, 465 villages, 156 Roman Catholic churches and 119 churches of ease, 40 Protestant and 5 churches of ease, 3 free churches, 211 Roman Catholic chapels, and 34 synagogues. The population in 1816, including the military, was 332,818; in the year 1828, 383,585, of whom 326,826 were Roman Catholics; 52,096 Protestants; and 4069 Jews; and in 1831, 386,938. It contains one university, that of Bonn, and four gymnasia. The stock consisted, in 1819, of 13,854 horses, 137,758 horned cattle, 61,568 sheep, and 11,716 goats; in 1831, of 15,610, 129,622, 62,221, and 10,465 respectively. The principal employments are the working of coal, lead, and iron mines, the potteries, and the manufacture of woollens, linen, leather, Cologne water, potash, sugar, and tobacco; besides dyeing, cotton printing, and tanning.

COLOGNE (Cöln), the capital of the circle, in 50° 58′ N. lat., and 6° 53′ E. long., extends in a crescent-shape along the left bank of the Rhine. It is enclosed by a lofty wall about 6 miles in circuit, defended by eighty-three towers, and surrounded with ramparts and deep ditches. It has twenty-four gates on the land and water-sides; and in front of the seven principal gates strong redoubts have been erected. Cologne owes its origin to the Romans. It was a Roman station, and subsequently a colonia, under the name of Colonia Claudia Agrippinensis, so called from the Emperor Claudius and his wife Agrippina, who was born here while her father Germanicus commanded in these parts. Agrippina adorned it with an amphitheatre, temples, aqueducts, &c., the ruins of which may still be traced. It continued to be the capital of Lower Rhenish Gaul till 330, and after a frequent change of masters was annexed to the German empire in 870. It took part in some of the many disputes which arose in the empire, and was besieged by Henry V. for its attachment to his father Henry IV.; and afterwards unsuccessfully by Philip of Swabia, for having proclaimed his rival Otto IV. In 1349, the principal Jews of Cologne, anticipating the same fearful persecutions as in other places, shut themselves up with their wives and children, and set fire to their houses; upon this, the surviving Jews were compelled to leave the city, and though they subsequently obtained permission to return, they were again obliged to quit it in 1429

Cologne was one of the most powerful and wealthy cities of the Hanseatic league. At that time it could muster an armed force of 30,000 men, and its population amounted to 150,000 souls. When the Hanseatic league engaged in a war with England in 1452, Cologne sided with England, on which account it was formally excluded from the league; but on the conclusion of peace by the treaty of Utrecht in 1474, it was re-admitted to this privilege upon the intercession of the Emperor Frederic III. During the whole of this period the commerce of Cologne was extremely flourishing. In the eleventh century the Colognese vessels carried Rhenish wines, corn, flour, malt, beer, linen, and other German produce to all countries lying on the German Ocean and the Baltic, to England, France, Spain, Portugal, Italy, Norway, Sweden, and Russia, and brought back the productions of those countries.

The trade of Cologne with England at this early period was very considerable, and King John conceded to the merchants of Cologne privileges rarely granted to his own subjects. Whitehall was the property of the city of Cologne, and allotted exclusively to the Rhenish trade. Cologne had a large factory in Norway and the Netherlands; and all vessels navigating the Rhine were obliged to unlade their cargoes at Cologne, whence they were conveyed in its own ships. The arts and sciences were equally flourishing; its university was one of the most famous in Germany. The specimens of its architecture, paintings on glass, sculptures, and pictures, which still exist, attest the perfection which its artists had attained. Intestine divisions, the expulsion of the Jews, the public destruction of its looms, which compelled their owners to emigrate, and various other causes, hastened its decline. It ceased to be a free town in 1792.

Cologne is divided into four sections, and is built in a very irregular manner; the streets, many of which still retain their Roman names, are narrow, dark and crooked, and paved with basalt. It contains twenty-five churches, eight chapels, a synagogue, and many public buildings, the most remarkable of which is the cathedral, which, if completed, would be the most magnificent monument of Gothic architecture in Europe. It was designed by Archbishop Engleberg of Berg, and was begun in 1284 by Archbishop Conrad of Hochstedten, called the Solomon of his age; it is in the form of a cross, 400 feet in length, and 180 in breadth; the roof rests on 100 columns, of which the four centre ones are 30 feet in circumference. The only part however which is finished is the splendid choir, with its surrounding chapels and its superb painted glass windows. Of the two towers, which were intended to be 500 feet in height, one is raised only half this elevation, and the other not more than 21 feet. Considerable progress is now making in completing various parts of the cathedral, under the direction of the Prussian government. It contains the tombs of Conrad, Mary de Medicis, &c., and abounds in relics and curiosities, especially the tomb of the Magi, which is richly adorned with gold and precious stones. Among the other interesting churches are those of St. Ursula, celebrated from the legend of the martyrdom of herself and 11,000 virgins, the churches of St. Columba, the Annunciation, St. Gereon, and St. Peter, which last contains a chef-d'œuvre of Rubens, representing the martyrdom of that apostle. The other buildings of note are the antient Carthusian convent, the town-hall, the hotel of Gurzenut, where the diet and festive meetings were formerly held, the hall of justice, the archiepiscopal palace, &c. Between Cologne and Deutz is a bridge built in 1822, which rests on 39 pontoons, and is 1250 paces long.

Cologne is the centre of the provincial administration, the residence of the archbishop, and the seat of various public boards. It contains two gymnasia; one Roman Catholic, which in 1827 had 484 scholars, and the other Protestant, with about 290 scholars: the latter has a valuable library of 33,000 volumes, an observatory, and a botanical garden. There is also the library of the town-hall, of the archbishop, which contains 10,000 volumes, a public archive, with valuable documents, collections of Roman antiquities, MSS., coins, natural history, &c. Besides several elementary schools for Protestants and Roman Catholics, the town has a grammar-school, a school of trades, three of commerce, a seminary for educating schoolmasters, an orphan asylum, hospital, mad-house, &c.

The population in 1827 was 57,022, of whom 54,000 were Roman Catholics, and 2385 Protestants; at present it exceeds 60,000. The chief resources of the inhabitants, besides agriculture and the cultivation of the vineyards, are manufactures, especially of cotton yarns, cotton goods, hosiery, woollens, silks, velvets, tobacco, brandy and spirits, Cologne water, &c. Being the central mart of the Rhenish trade between the Netherlands, Germany, Alsace, and Switzerland, many of the inhabitants are engaged in shipping, and Cologne being a free port, a considerable traffic is carried on in corn, wine, rape-seed, rape-seed oil, coals, &c. In the vicinity of the city are several coal-mines, and abundance of a particularly fine sort of porcelain-earth and potter's clay.

COLOMBIA is the name which was adopted by the northern countries of South America in 1819, when New Granada and Venezuela united and established one central government for the purpose of resisting the Spanish government. In 1829 Venezuela renounced the union, and constituted itself a separate republic. After the resignation of Bolivar in 1830, it again joined New Granada; but this union lasted only a short time. In November, 1831, a new separation took place, and at the same time it was decided that the former province of Quito should constitute a separate republic under the name of Ecuador. Thus Colombia was divided into the three republics of Venezuela, New Granada, and Ecuador.

COLON. The alimentary canal below the stomach is divided into the small and great intestines. The former consist of the duodenum, jejunum, and ileum; the latter of the colon and rectum. The *colon* commences a little above the right groin, in the right iliac fossa [ABDOMEN], in the form of a dilated pouch, which is called the *caput coli*, or more commonly the *cœcum*, from its blind rounded extremity. The ileum opens obliquely into the left side of this pouch, its inner or mucous membrane projecting so as to form the *ileo-cœcal valve*, which, permitting the contents of the small intestine to pass into the colon, suffices to prevent their return, except in peculiar cases of diseased action. Near the same part of the cœcum opens also a slender contorted intestine about two inches long, likewise blind, which is called the *appendix vermiformis*, from its resemblance in the human subject to a worm. The use of this appendage is unknown: in some animals, as the sheep, it is much larger, and is probably of more importance than in man. From the right iliac region the colon passes upwards along the side to the under surface of the liver. Hence it turns to the left, stretching over the upper part of the belly just below and in front of the stomach, to which it is connected by the common attachment of both organs to the *omentum*, a loose pendulous membrane, formed by a double fold of the peritoneum, and spread like an apron in front of the small intestines. Having reached the opposite side of the abdomen, the colon passes downwards to the left iliac fossa; thence, taking two sudden turns to the right and downwards, it descends into the pelvis over the last lumbar vertebra, and becomes continuous with the rectum. The double turn just mentioned is the *sigmoid flexure;* the transverse part is called the *arch* of the colon, and the ascending and descending or lateral parts, as they lie immediately over the loins, are called the right and left *lumbar* portions. The central space thus nearly encircled by the colon is occupied by the convoluted heap of small intestines. The length of the whole canal is six or seven times that of the body in man, the colon constituting about a fifth part. In graminivorous animals its length is proportionably greater; in those which feed exclusively on flesh it is less.

The colon is enveloped in the serous membrane called the peritoneum, which forms the external covering of all the abdominal viscera. [ABDOMEN.] This outer tunic passing entirely round it, meets behind, and forms a duplicature called the *mesocolon*, which attaches it, more loosely at the arch than at the sides, to the spine and loins, and serves as a medium for the passage of nerves and vessels, and the lodgment of absorbent glands. Between the peritoneal coat and the interior mucous lining, there is a layer of muscular fibres, some of which encircle the bowel in scattered bands, and serve to diminish its calibre; others, more regularly arranged in three distinct longitudinal bands, contract its length; and their combined actions, taking place successively in different parts of the intestine, but on the whole propagated from above downwards, agitate its contents backwards and forwards, and urge them ultimately into the rectum.

The colon is amply supplied with blood-vessels, nerves, lymphatics, and ducts, which pour out the mucus that lubricates the interior as well as various excrementitious matters here separated from the blood as being injurious or useless. The canal is not smooth and uniform, like the small intestines, but bulges out between the bands of muscular fibre into various prominences more or less regular in their form, in which the fæces lodge for a time and become deprived of much of their moisture as they are rolled onwards by the peristaltic action. Hence arises their lobulated or globular form, more observable in some of the lower animals, as the horse and sheep, than in man. It is in the colon that the fæces acquire their peculiar odour, which is not perceived above the ileo-cœcal valve. It is in this part of the alimentary canal that the fluid part of the food is chiefly absorbed, being no longer needed to keep the nutritive particles in suspension. The lymphatic vessels of the colon are consequently found distended with a transparent fluid, and not the milk-like chyle absorbed by those of the small intestines. [LACTEALS, LYMPHATICS.] For further information on the functions of the colon, the reader is referred to the account of those of the alimentary canal in general, given under the head of DIGESTION.

The colon is alone or conjointly the seat of many disorders, such as cholera, colic, constipation, diarrhœa, dysentery, enteritis, ileus, introception, obstruction; and is liable to ulceration in the course of hectic and other fevers, as well as from local causes. It is occasionally the seat of stricture; and is not unfrequently protruded in the various forms of intestinal rupture.

COLONEL, the commander of a regiment or battalion of troops; he is the highest in rank of those called field-officers, and is immediately subordinate to a general of division.

The derivation of the word is uncertain. It is supposed to have been given originally to the leader of a body of men appointed to found a colony; or to have come from the word *coronarius*, indicating the ceremony of investing an officer with the command of a corps; or, finally, from the word *columna*, denoting the strength or support of an army.

The title of colonel-general was, for the first time, conferred by Francis I., about the year 1545, on officers commanding considerable divisions of French troops, though, according to Brantome, it had been given to the chief of an Albanian corps in the service of France at an earlier period. When the troops of that country were formed into regiments (the infantry about 1565, and the cavalry seventy years afterwards), the chiefs of those corps were designated *Mestres de Camp*; and it was not till 1661, when Louis XIV. suppressed the office of colonel-general of infantry, that the commanders of regiments had the title of colonel.

In England, the constitution of the army was formed chiefly on the model of the French military force; and the terms regiment and colonel-general were introduced into this country during the reign of Elizabeth. It must, moreover, be observed, that in the regulations made by the citizens of London for forming the militia in 1585, it is proposed to appoint *colonels* having authority over ten captains; and that both colonels and lieutenant-colonels are distinctly mentioned in the account of the army which was raised in order to oppose the threatened invasion of the country in 1588. Before the time of that queen, it appears that the commanders of bodies of troops equivalent to regiments had only the general title of captain.

The duties of colonels are described in Ward's 'Animadversions of Warre,' which was published in 1639; and from the account there given, it appears that those duties were then nearly the same as they are at present. To the colonel of a regiment, besides the general superintendence of the military duties performed by the troops composing it, is intrusted the care of providing the clothing of the men and of appointing the agent through whom their pay is transmitted. Colonels take precedence of one another according to the dates of their commissions, and not according to the seniority of their regiments.

The lieutenant-colonel is immediately under the full colonel. He assists the latter in directing the evolutions of the battalion or regiment, which he also commands during the absence of his superior officer.

The annual pay of a colonel is, in the Life Guards, 1800*l.*; in the Grenadier Guards, 1200*l.*; in the Coldstream and Scots Fusilier Guards, 1000*l.*; in the cavalry regiments generally 900*l.*; and in the regular infantry, 500*l.* The daily pay of a lieutenant-colonel is, in the Life Guards, 1*l.* 9*s.* 2*d.*; in the Foot Guards, 1*l.* 6*s.* 9*d.*; and in the infantry, 17*s.* The price of a lieutenant-colonel's commission is, in the Foot Guards, 9000*l.*; in the Life and Horse Guards, 7250*l.*; in the Dragoons, 6175*l.*; and in the infantry of the line, 4500*l.*

COLONIZATION SOCIETY, AMERICAN. [SLAVERY.]

COLONNA is the name of one of the oldest and most illustrious families of Italy. About 1050 it became possessed of the feudal estate of La Colonna on the Tusculan mount. Pietro, lord of Colonna, who lived in the twelfth century, is one of the earliest of the family recorded in history. His son Giovanni was made cardinal by Honorius III., in 1216. The family afterwards divided into several branches, one of which became princes of Palestrina; another dukes of Zagarolo; while others were made dukes of Traietto and counts of Fondi, dukes of Paliano and Tagliacozzo, and princes of Sonnino and Stigliano, in the kingdom of Naples. Moreri, art. 'Colonna,' gives their respective genealogies. At one time they were possessed of a great portion of the Campagna of Rome, besides large estates in Abruzzo. The Colonna were of the Guibeline party: their rivalry with the Orsini and other Roman barons, and their quarrels with several popes, especially with Boniface VIII., are recorded in the history of the middle ages. In the early part of the fifteenth century, one of the Colonna family was made pope under the name of Martin V. A century later, two cousins of the same family, Fabrizio and Prospero Colonna, distinguished themselves in the service of Ferdinand of Aragon, and afterwards of Charles V., against the French in Italy. Several of the same family attained high honours in the kingdom of Naples and in Spain, and others are numbered among the cardinals of the Roman church. Some branches of the family have become extinct, but the Stigliano of Naples and the Sciarra Colonna at Rome continue to exist. The Colonna have an extensive palace with gardens on the slope of the Quirinal at Rome.

COLO'NNA, VITTO'RIA, born in 1490, was the daughter of Fabrizio Colonna, Great Constable of the kingdom of Naples, and of Anna, the daughter of Frederico di Montefeltro, duke of Urbino. At the age of seventeen she married Francis Davalos, son of the marquis of Pescara, who soon after came to the title at the death of his father. Pescara served with distinction in the armies of Charles V., and contributed greatly to the gaining of the battle of Pavia, in which he was wounded. On his recovery, appearing dissatisfied with Charles V., he was sounded by Morone, the old minister of the Duke Sforza of Milan, as to his willingness to enter into a plot concerted with the other Italian princes, by which the Spanish troops were to be driven out of Milan and Lombardy, and ultimately from all Italy. Pescara was then commander-in-chief of Charles's army in Italy. He was promised the kingdom of Naples as a reward for his assistance in the execution of the plot. Pescara appeared to assent at first, but afterwards secretly informed Charles V., who is said, however, to have had already some previous information on the subject, and who ordered him to take possession of the principal towns of Lombardy, and to arrest Morone, who was soon after put to death. It is reported that Vittoria Colonna contributed by her remonstrances on this occasion, to retain her husband within the bounds of his allegiance to the emperor. Shortly after Pescara died towards the end of 1525, aged thirty-six years, and was succeeded by his cousin the marquis del Vasto in the command of the Imperial army in Italy. Vittoria Colonna, who was inconsolable for the death of her husband, determined on spending the remainder of her life in religious seclusion, although various proposals of a second marriage were made to her. She wrote several poetical effusions, lamenting the death of her husband, and also upon religious subjects. (*Rime Spirituali di Vittoria Colonna*, Venezia, 1548.) Her beauty, her talents, and her virtue, were extolled by her contemporaries, and among others by Michael Angelo, and by Ariosto, in canto 37 of the 'Furioso.' She died in 1547, at Rome, and was styled 'a model of Italian matrons.' (Corniani, Tiraboschi, &c.)

COLONNADE. [CIVIL ARCHITECTURE.]

CO'LONY, in Latin colonia, a word derived from the verb colo, colere, to till or cultivate the ground, originally signified a number of people transferred from one country or place to another, where lands were allotted to them. The people themselves were called Coloni, a word corresponding to our term colonists. The meaning of the word was extended to signify the country or place where colonists settled, and is now often applied to any settlement or land possessed by a sovereign state upon foreign soil. Thus Ceylon and the Mauritius are called British colonies, though they are not colonized by Englishmen, the former being inhabited by natives, and the second by French or descendants of French colonists. The proper notion of the word 'colony' (as determined by the general use of the term) seems to be a tract of land, either wholly or partly colonized, that is to say, possessed and cultivated by natives, or the descendants of natives, of another country, and standing in some sort of political connection with and subordination to the mother country.

The formation of colonies is among the oldest occurrences recorded in history or handed down by tradition. Maritime states, such as those of Phœnicia and of Greece, possessing only a scanty territory, would naturally have recourse to emigration as their population increased. In both these countries the sea afforded a facility for transferring a part of their superabundant citizens, with their families and movables, and their arms, to some foreign coast, either uninhabited or thinly peopled by less civilized natives, who by good will or by force, gave up to them a portion of their land. The emigration might be voluntary or forced; it was no doubt in many cases the result of civil contentions or foreign conquest, by which the losing party were either driven away, or preferred seeking a new country to remaining at home. The report of some remote fertile coast abounding in valuable productions would decide others. Lastly, the state itself having discovered, by means of its merchants and mariners, some country to which they could trade with advantage, might determine upon sending out a party of settlers and might establish a factory there for the purpose of sale or exchange. In fact commercial enterprise seems to have led both to maritime discovery and to colonization as much as any one single cause. Such seem to have been the causes of the numerous Phœnician colonies which, at a very early date, were planted along the coasts of the Mediterranean. Tyre itself was a colony of Sidon, according to the 'Old Testament,' which calls it the 'daughter of Sidon.' Leptis Magna, near the great Syrtis, was also a colony of Sidon, according to Sallust (*Jugurth.* c. 78). Hippo, Hadrumetum, Utica, and Tunes, were Phœnician colonies, and all of greater antiquity than Carthage. The Phœnician colonies extended along the north coast of Africa as far as the Pillars of Hercules (the Straits), and along the opposite coast of Spain, as well as on the Balearic Islands, and Sardinia and Sicily. Those on the Spanish coast seem to have been at first small settlements or factories for the purpose of trade between the metropolis or mother country and the natives. Several of them, however, such as Gades, by degrees took the trade into their own hands and became independent of the mother country. The foundation of Carthage was an instance of another kind. It resulted, according to tradition, from an emigration occasioned by the tyranny of a king of Tyre. There is another confused tradition of a Phœnician or Cànaanite emigration to Mauritania, occasioned by the conquest of Palestine by Joshua, and mentioned by Procopius and Suidas, as well as by some Jewish commentators [BERBERS]. The Phœnicians very early settled in the fertile island of Cyprus, which lay opposite their own coast. Of their settlements in the islands of the Ægean Sea we have only traditions referring to times previous to the war of Troy, and mentioned by Herodotus, and after him by Thucydides, who says that the Phœnicians and the Carians inhabited most of the islands, and carried on piracy, until Minos, king of Crete, drove them away, and planted new colonies. Herodotus says they had once a settlement in the island of Thasus, where they worked the gold mines. They also had a settlement on the island of Cythera (Cerigo), which lay conveniently for their trade with the Peloponnesus. Thucydides (vi. 2, &c.) also mentions that the Phœnicians formed establishments on the promontories and small islands on the coast of Sicily, from which they traded with the native Siculi; but that when the Greeks came to settle in great numbers in that island, the Phœnicians abandoned several of their posts, and concentrated themselves at Motya, Soloeis and Panormus, now Palermo (which last probably had then another name), near the district occupied by the Elymi or Phrygian colonists (who had emigrated from Asia after the fall of Troy, and had built Entella and Egesta), trusting to the friendship of the latter and also to their proximity by sea to their countrymen of Carthage. These three Phœnician settlements however merged afterwards into Carthaginian dependencies. The Phœnicians appear also to have occupied Melita or Malta, and the Lipari islands, one of which retained the name of Phœnicusa. Of the Phœnician settlements in the south part of Sardinia we have the report of Diodorus (v.) and a fragment of Cicero pro Scauro, published by Mai. The Phœnicians and Libyans are said to have been the earliest settlers in Sardinia, and to have founded Caralis (Cagliari) and Sulci. A Phœnician inscription was found in a vineyard at Cape Pula, belonging to the monks of the order of Mercy, and was explained by De Rossi, *Effemeridi Letterarie di Roma*, 1774. But the undoubted field of Phœnician colonization was the north coast of Africa. There the Phœnician settlements seem to have been independent, both of the mother country and of each other. We have the instance of Utica and Tunes, which continued separate communities even after Carthage had attained its great power; Carthage only exercising the hegemony or supremacy. This seems to have been the case among the original Phœnician towns; Sidon, Tyre, Aradus, &c., each a distinct common wealth, forming a sort of federation, at the head of which was the principal city, at first Sidon, and afterwards Tyre. A feeling of mutual regard seems to have prevailed to the last between the various Phœnician towns and colonies, including Carthage, as members of one common family.

The colonies established afterwards by the Carthaginians in the interior as well as on the coast of Africa, Sicily, and Spain, were upon a different plan from those of the Phœnicians: they were made through conquest and for the purpose of keeping the country in subjection, like those of the Romans [CARTHAGE], with the remarkable exception of the emigration colonies taken by Hanno to the west coast of Africa.

The earlier Greek colonies appear to have owed their origin to the same causes, and to have been founded upon the same plan as those of the Phœnicians. Thucydides (I.) says, that 'after the Trojan war, and the subsequent conquest of Peloponnesus by the Dorians, Greece being restored to tranquillity, began to send out colonies. The Athenians, whose country was overflowing with people from other parts of Greece, who had flocked thither for security, began to send out colonies into Ionia and to many of the islands; the Peloponnesians sent theirs to Italy, Sicily, and some parts of Greece. But all these colonies were sent after the Trojan war.' The Dorians from Megaris, Argos, Corinth, and other places, colonized some of the larger islands, part of Creta, Rhodes, Corcyra, as well as Ægina, Cos, &c. They founded the Hexapolis on the south-west coast of Caria, in Asia Minor, which district took from them the name of Doris. A colony of Lacedæmonians founded Cyrene. The Megarians founded Chalcedon, Byzantium, Selymbria, Heraclea, and other places on the coasts of the Euxine. Sicily also was chiefly colonized by Dorians. Syracuse was a Corinthian colony, which afterwards founded Acræ, Camarina, &c.; Gela was a colony of Rhodians and Cretans, and Agrigentum was a colony from Gela. The Megarians founded Selinus. The Chalcidians built Naxus, which was the first Greek settlement in Sicily, and afterwards took Leontini and Catana from the Siculi. For a more detailed account of the numerous Dorian colonies see K. O. Müller's *History of the Doric Race*.

The Ionians from Attica, another great branch of the Hellenic stock, after the death of Codrus, the last king of Athens, emigrated to the west coast of Asia Minor, which took its name from them [IONIA], and established there twelve cities or communities, which quickly rose to a high degree of prosperity, and formed a kind of federal union. About eighty years before, the Æolians and Achæans, two nearly allied races, being driven away from Peloponnesus by the Dorians, had emigrated to the coast of Asia Minor, where they formed colonies from Cyzicus on the Propontis as far southwards as the Hermus. Phocæa was the most northern of the Ionian towns on the borders of Æolis. The Æolians also colonized the islands of Lesbos, Tenedos, and others in that part of the Ægean. These emigrations were posterior to the time of Homer, who mentions other people as occupying that coast. The Athenians at a later date colonized Eubœa, where they founded Chalcis and Eretria, and they also sent colonies to Naxos, to the islands of Ceos, Siphnos, Seriphos, and other islands of the Ægean. Many of these colonies having thriven and increased, became colonizers in their turn. The enterprising mariners of Phocæa formed various colonies, the most celebrated of which is Massilia on the south coast of Gaul. The Chalcidians of Eubœa founded Cumæ, on the west coast of Italy, in the country of the Opici. Pirates from Cumæ founded Zancle, but a fresh colony of Samians and other Ionians escaping from the Persian invasion, in the time of the first Darius, took Zancle, and were afterwards in their turn dispossessed by Anaxilas, tyrant of Rhegium, who called the town Messene (now Messina), from the name of his original country in the Peloponnesus. The Æolians founded Dicæarchia, afterwards Puteoli, and they with the Cumæans are believed to have founded Parthenope (Naples). Ionian colonists settled on the coast of Sardinia.

The Greek colonies on the east coast of Italy, setting aside the confused traditions of Arcadian immigrations, Pelasgian, &c., supposed to have taken place before the Trojan war, consisted chiefly of Dorians and Achæans from the Peloponnesus. Croton, Sybaris, and Pandosia were colonies of the latter. Tarentum was a colony of Lacedæmonians, and Locri Epizephyrii of the Locrians. Greek colonies were settled both on the north and east sides of the Pontus (Black Sea), and also on the north coast in the modern Crimea. [Bosporus.]

As to the relations subsisting between the colonists and the natives or prior inhabitants of the countries which they occupied, it was undoubtedly in most cases strictly in accordance with the right of the strongest. Either the natives withdrew into the interior and left the ground to the new occupants, as the Siculi did in several instances, or they resisted, in which case, when overpowered, the men were exterminated or reduced to slavery, and the conquerors kept the women for themselves. In some instances the older inhabitants were reduced to the condition of serfs or bondmen to the new settlers. The records of authentic history do not present us with an instance of any colony being settled in a country where there were not previous inhabitants. The consequence of the immigration of a new race, who seek to possess themselves of the land, must be the extermination or gradual decay of the prior race, unless the old inhabitants are made slaves. So far as we trace the history of Greek colonies in the scattered fragments of antiquity, such were the consequences of their colonial settlements. On the coast of Italy it would appear that the Greeks pursued a more humane or more politic course. They are said to have allied themselves to and intermarried with the natives, and by their superior civilization to have acquired great influence. It may here be remarked that the Greeks, so far from being averse to foreign intermixtures, as some have said, mingled their blood freely with that of all the nations with whom they came into contact, and thus the civilization of the Hellenic stock was gradually introduced among nations less advanced in the useful arts.

What were the relations between these Greek colonies and the mother country, and between those colonies that were of a kindred race?

This may be gathered pretty clearly from Thucydides. Epidamnus was a colony of Corcyra: but the leader of the colony (οἰκιστής), the founder of the colony, or the person under whose conduct it was settled, was a Corinthian, who was called or invited, says Thucydides, from the mother city (called by the Greeks the metropolis, μητρόπολις, or parent state), according to an antient usage. Thus it appears that if a colony wished to send out a new colony, this was properly done with the sanction of the metropolis. Some Corinthians and other Dorians joined in the settlement of Epidamnus, which became a thriving community, and governed itself independently of both mother countries. In the course of time, however, civil dissensions and attacks from the neighbouring barbarians induced the Epidamnians to apply to Corcyra, as their metropolis, for assistance, but their prayers were not attended to. Being hard pressed by the enemy, they turned themselves to the Corinthians, and gave up their town to them, as being the real founders of the colony, in order to save themselves from destruction. The Corinthians accepted the surrender, and sent a fresh colony to Epidamnus, giving notice that all the new settlers should be on an equal footing with the old settlers: those who did not choose to leave home were allowed to have an equal interest in the colony with those who went out, by paying down a sum of money, which appears to have been the price of allotments of land. Those who went out gave their services; those who stayed at home gave their money. 'Those who went out,' says Thucydides, 'were many, and those who paid down their money were also many.' For the moneyed people it was in fact an affair of pure speculation. The Corcyræans, themselves originally a colony from Corinth, having become very powerful by sea, slighted their metropolis, and 'did not pay to the Corinthians the customary honours and deference in the public solemnities and sacrifices, as the other colonies were wont to pay to the mother country.' They accordingly took offence at the Corinthians accepting the surrender of Epidamnus, and the result was a war between Corcyra and Corinth. (i. 24.)

Again, the Corcyræan deputies, who were sent to court the alliance of the Athenians against Corinth, stated, in answer to the objection that they were a colony of Corinth, that 'a colony ought to respect the mother country as long as the latter deals justly and kindly by it, but if the colony be injured and wrongly used by the mother country, then the tie is broken, and they become alienated from each other, because, said the Corcyræans, colonists are not sent out as subjects, but as free men having equal rights with those who remain at home.' (i. 34.) This shows the kind of relation as understood by the Greeks between the metropolis and its colonies. The colonies were in fact sovereign states, attached to the mother country by ties of sympathy and common descent, so long as those feelings were fostered by mutual good-will, but no further. The Athenians, it is true, in the height of their power, exacted money from their own colonies as well as from the colonies of other people, and punished severely those who swerved from their alliance, such as Naxos; but this was not in consequence of any original right of dominion as supposed to belong to the mother country over the colony. Many of the colonies, especially the earlier ones, which were the consequence of civil war or foreign invasion, were formed by large parties of men under some bold leader, without any formal consent being asked from the rest of the community: they took their families, their arms, and their movables with them, to conquer a new country for themselves; they left their native soil for ever, and carried with them no obligations or ties. Those that went off in more peaceful times, by a common understanding of the whole commonwealth, went also away for ever, and freely and voluntarily, though under a leader appointed by the parent state, to seek a country where they could find an easier subsistence than at home. In either case it was a complete separation of a member from the body. When the Athenians, in later times, took possession of parts of Eubœa (Thucyd. i. 114), and of Ægina (ii. 27), of Melos (v. 116), and shared the lands among their own citizens who went there, the relationship thus formed was of a different kind. In the case of Ægina the whole population, which was of Hellenic stock, was turned out, and a body of Athenians occupied their place, with the express object of being as a body or community subordinate to the state of Attica, in order to prevent the annoyance to which Attica had long been subject by the proximity of an independent island so well situated both for the purpose of annoying Attica and for self-defence.

That the colonies of a kindred race should feel a common interest in opposition to those of a rival branch is natural, and is proved among other instances by the case of the deputies from Egesta in Sicily, who, while requesting the assistance of the Athenians against the Syracusans and Selinuntians, urged as an additional plea that the Leontines, who were originally Chalcidians, and therefore akin to the Athenians, had been expelled from their town by the Syracusans, and showing that it was the interest of the Athenians to assist a kindred people against the prevailing power of the Dorian colonies in Sicily. (Thucyd. vi.)

Before we pass to the Roman colonies, we must say something of the system of colonization among the other inhabitants of the Italian peninsula in the Ante-Roman times. The Etruscans extended their conquests north of the Apennines in the great plain of the Po, and founded there twelve colonies, the principal of which was Felsina (Bologna). They afterwards, having defeated the Umbrians, many years before the assumed foundation of Rome, extended themselves into East and South Italy, penetrated into Latium, and took Campania from the Oscans, where they founded likewise twelve colonies, the principal of which was Capua. The Etruscans, being skilled in architecture, surrounded their towns with solid walls built of massive stones without any cement; they were also well versed in agriculture and hydraulics, and several of the earliest drains and canals in the Delta of the Po are attributed to them. They subjected, but at the same time necessarily civilized, the people among whom they settled. Their colonies seem to have formed independent communities, though allied by a kind of federation. The Etruscans also founded colonies in the Picenum, such as Hatria [Atri] and Cupra Montana and Cupra Maritima. They took from the Ligures the country around the gulf now called Della Spezia, and founded the city of Luna. They likewise sent colonies to the islands of Elba and Corsica, for the Etruscans were a commercial as well as agricultural people; they navigated the sea, and in the sixth century B.C. they defeated the Phocæans, and drove them out of Corsica. The Etruscans civilized Italy by means of their colonies, but, unlike Rome, they did not keep them united under a central power.

The Sabini, an agricultural and pastoral people, living in a mountainous country, sent colonies in very remote times to other parts of Italy. It was their custom, after the lapse of a certain number of years, to celebrate solemn sacrifices in the spring season, and to consecrate to the gods a number of young men, who were to quit their native land, and proceed under the auspices of Heaven to seek a new country. In this manner the Piceni and the Samnites are said to have been colonies of the Sabini. The Samnites in their turn sent out other colonies, and the Lucanians were one of these. The Samnites as well as the Sabini were entirely given to agricultural pursuits.

Rome, in the earliest ages of the republic, adopted the system of sending out colonies to the conquered countries. But the Roman colonies were different from those of most other people, inasmuch as they remained strictly subject to the mother country, whose authority they were the means of enforcing upon the conquered nations. They were, in fact, like so many garrisons or outposts of Rome. Servius (Æn. i. 12) gives the following definitions of a colony, taken from much older authorities:—'A colony is a society of men led in one body to a fixed place, furnished with dwellings given to them under certain conditions and regulations.' Again, 'Colonia is so called a colendo; it consists of a portion of citizens or confederates sent out to form a community elsewhere by a decree of their state, or with the general consent of the people from whom they are departed. Those who leave without such a consent, but in consequence of civil dissensions, are not colonies.' The notion of a Roman colony seems to be this: the colonists occupied a city already existing; and this, with perhaps one exception or two, was the general character of the Roman colonies in Italy Proper. When the Romans afterwards extended their conquests into countries where there were no regular towns, or where the population being fierce and hostile, the Roman settlers must be ever on their guard against them, they built new towns in some favourable position. Such was the case in several parts of Gaul, Germany, Dacia, &c. But the Roman colonies in Italy consisted of Roman citizens, who were sent as settlers to fortified towns taken in war, with land assigned to them at the rate of two jugera of arable land or plantation for each man, besides the right of pasture on the public or common land. The old inhabitants were not ejected, or dispossessed of all their property; the general rule was, that one-third of the territory of the town was confiscated and distributed among the colonists, and the rest was left to the former owners, probably subject to some charges in the shape of taxes, or services. The colonists constituted the *populus* of the place; they alone enjoyed political rights and managed all public offices, the old inhabitants being considered as the plebs. The ownership of the publicum or public property, including the pasture land, was probably also vested in the new settlers. It is natural to suppose, that for some generations at least, no great sympathy existed between the old and the new inhabitants, and hence we frequently hear of revolts of the colonies, which means, not of the colonists against the mother city, but of the old inhabitants, who rose upon and expelled the colonists. But these events generally ended by a second conquest of the place by Roman troops, when the old inhabitants were either put to the sword or sold as slaves, or, under more favourable circumstances, lost at least another third of their property. In later times, during the civil wars of Rome, new colonies were sent by the prevailing party to occupy the place of the former ones; and the older colonists were then dispossessed of their property either wholly or in part, just as they had dispossessed the original inhabitants. Hence the saying, 'Veteres migrate coloni.' Sometimes colonies, especially at a great distance from Rome, having dwindled away, or being in danger from the neighbouring populations, asked for a reinforcement, when a fresh colony was sent, to whom the old colonists gave up one-third of their property. Each of the older colonies, it is observed by Gellius (xvi. 13), was a Rome in miniature; it had its senators called Decuriones, its Duumviri, Ædiles, Censores, Sacerdotes, Augurs, &c.

A distinction must here be made between the Roman colonies and the Latin colonies. The former had all or nearly all the rights of the citizens of Rome, although Sigonius and some others pretend that they had not the jus suffragii; and yet, in various passages of Livy and others, colonists are styled cives and Romæ censi. The Latin colonies had not the jus Quiritium, but only the jus Latii. All those, however, who filled magistrates' offices in Latin colonies became Roman citizens. Such was the case with Tibur, Præneste, &c. The towns of Transpadane Gaul, as a reward for their fidelity to Rome, obtained the rank of Latin colonies without any colonists being sent to them.

There were also military colonies, which consisted of soldiers, to whom land was given instead of pay and provisions, as a resting-place after their campaigns. Sulla appears to have been the founder of these, and Cæsar and Augustus added greatly to their number. These colonies are distinguished by having military ensigns on their coins, while the Coloniæ Togatæ, or citizen colonies, have a plough on theirs. (Heinec. *Antiqu. Roman. Syntagma.*) The coins of some colonies have both marks, which means that the original colony consisted of citizens, after which a second was sent, composed of military. In Tacitus (*Annal.* i.) the veterans complain that, after their long service, they were rewarded only with uncultivated lands, situated in the neighbourhood of the enemies of the empire.

The system of colonies adopted by Rome had a double political object; to secure the conquered countries, and to satisfy in part the claims of its own poorer citizens, and to get rid of turbulent characters. The importance of the Roman colonies to the empire is well expressed by Cicero, who calls them 'propugnacula imperii et speculæ populi Romani.' Such they doubtless were, and at the same time they were the germ of the civilization of Northern and Western Europe. A nation of civilized conquerors, whatever evils it may inflict to gratify its own cupidity, confers on the conquered people unintentionally still greater benefits. By their colonies in Spain, Gaul, on the banks of the Rhine, and in Britain, the Romans established their language and their system of administration. The imprint of their empire is indelibly fixed on the existing nations of Europe.

The difference between Colonia and Municipium is that the latter was a town of which the inhabitants, being friendly to Rome, were left in undisturbed possession of their property and their local laws and political rights, and obtained moreover the Roman citizenship, either with or without the right of suffrage; for there were several descriptions of Municipia. [MUNICIPIUM.] The colonies, on the contrary, were all governed according to the Roman laws. The Municipia were foreign limbs engrafted on the Roman stock, while the colonies were branches of that stock transported to a foreign soil.

Under the later Roman Emperors, the difference between Colonia and Municipia became obliterated, and all were governed alike according to the Roman law, and a uniform system of administration. Augustus gave the right of Roman citizenship to all Italy. Antoninus Caracalla bestowed it upon all freemen, subjects of the empire. (For the Roman colonies see Niebuhr, vol. ii.; Manutius *de Civitate Romana;* Sigonius *de Ant. Jure Ital.;* Heineccius, *Syntagma, &c.*)

The northern tribes who overthrew the western empire did not found colonies; they overran or conquered whole provinces, and established new states and kingdoms. The same may be said of the Saracen conquests in Asia and Africa. But, after a lapse of several centuries, when Europe had resumed a more settled form, the system of colonization was revived by three maritime Italian republics, Pisa, Genoa, and Venice. Their first settlements on the coasts of the Levant and Egypt were mercantile factories; which the insecurity of the country soon induced them to convert into forts with garrisons, in short into real colonies. The Genoese established colonies at Famagosta in Cyprus, at Pera and Galata, opposite to Constantinople, at Caffa in the Crimea, founded in 1266; they also acquired possession of a considerable extent of coast in that peninsula, forming a district subject to Genoa under the name of Gazaria. Another tract, on the coast of Little Tartary, called Gotia, was also subject to the Genoese, who had then the colony of Cembalo. In the Palus Mæotis they had the colony of La Tana, now Azof. On the south coast of the Euxine they possessed Samastro or Amastri; they had also a factory with franchises and their own magistrates at Trebizond, as well as at Sebastopolis. These colonies were governed by consuls sent from Genoa, and the order and justice of their administration have been much extolled. In the archives of St. George, at Genoa, there is a valuable unpublished MS. containing the whole colonial legislation of the Genoese in the middle ages.

The Pisans, having taken Sardinia from the Moors, sent colonies to Cagliari and other places. Their settlements in the Levant were mere commercial factories.

The Venetians established colonies in the Ionian islands, Candia, and Cyprus. Their system resembled that of Rome; they ruled, by means of their colonies and garrisons, over the people of those islands, whom they left in possession of their municipal laws and franchises. These were not like the settlements of the Genoese, merely commercial establishments—they were for conquest and dominion; in fact, Candia and Cyprus were styled kingdoms subject to the Republic. The Venetians had also at one time factories and garrisons on various points of the coasts of the Levant, but they lost them in the Morea, Eubœa, Syria, and the Euxine, either through the Genoese, or afterwards by the arms of the Ottomans. We can hardly number among their colonies the few strongholds they had until lately on the coast of Albania, such as Butrinto, Prevesa, Parga, &c., any more than those possessed by the Spaniards and Portuguese on the coast of Barbary, Oran, Melilla, Ceuta, &c. They were merely forts with small garrisons, with no land attached to them. The name used in the Mediterranean for such places is presidii; and they are often used as prisons for criminals. An essential qualification of a colony is that it should have and cultivate land, and consist at least in part of civilians. The great question agitated now in France, with regard to Algiers, turns upon this,—whether the French are merely to occupy the towns on the coast as military and in some degree commercial colonies, or establish a great agricultural colony in the interior, by taking possession of and cultivating the land. This question, as well as that of most modern colonies, touches several points both of justice and policy. When a colony is sent to a country occupied by a few hunting tribes, as was the case in part of North America at the time the English settled there, and as is now the case in New Holland, the taking possession of part of the land for the purpose of cultivation is attended with the least possible injury to the aborigines, while, at the same time, it has in its favour the extension of civilization upon a new shore. The savages generally recede before civilized man; a few of them adopt civilization, and the rest become gradually extinct. When the limits are confined, the progress towards extinction is exceedingly rapid. The aborigines of Van Diemen's Land are now, as we are informed, reduced to a very small number, and perhaps that small number may, at this moment, have been reduced to nothing. This, however melancholy in one point of view, has been, from the earliest times, the great law of the progress of the human race. But the case is much altered when the natives are partly civilized, live in domestic societies, have settled habitations, and either cultivate the land or feed their flocks upon it. The colonists in such case do what the Romans did in their colonies; they take part of the arable land, or the whole of the common or pasture land, and leave to the natives just what they please, and if the latter resist, they kill them. Whether this be justice every man may ask himself. Such however has been the system pursued by the Spaniards in various parts of America, by the Dutch at the Cape and the Molucca islands, and by all maritime nations in some part or other of Asia, Africa, or America; and this is now attempted to be done by the French against the Arabs and Kabyles of the state of Algiers. The case may be one of greater or less oppression; according as the land is either enclosed and cultivated, or merely used for pasture or the chase, and according as the natives are more or less numerous in proportion to the land, colonization may proceed on a milder or harsher system; still the question of justice remains the same, unless the natives be willing to part with their land by amicable arrangement. This system of purchase from the natives has been practised both by the English and Anglo-Americans in North America; but though it has the specious name of bargain, it has often been nothing more than a fraud, or sale under compulsion. The man of Europe has been long accustomed to regard the possession of the soil as that which binds him to a place, and gives him the most secure and least doubtful kind of property. His habits of accumulation, and of transmitting to his children a permanent possession, make him covet the acquisition of land. In whatever country he has set his foot, and once got a dominion in the soil, neither contracts, nor mercy, nor feelings of humanity, nor the religion which he carries with him, have prevented him from seizing on the lands of the owners, and punishing their resistance with death.

The modern colonies in Asia and America have been formed partly on the Roman or Venetian and partly on the Genoese or old Phœnician principle. When the Portuguese first began their voyages of discovery in the 15th century, they took possession of some islands or points on the coasts of Africa and of India, and left there a few soldiers or sailors under a military commander, who built a fort to protect the trade with the natives, and afterwards also to keep those natives under a sort of subjection. No great emigrating colonies were sent out by them, except in after times to Goa and the Brazil, which latter is really a colony of Portuguese settlers. The Spaniards, on the contrary, when they discovered America, took possession of the soil, and formed real colonies kept up by successive emigrations from the mother country. In the West India Islands the natives were made slaves, and by degrees became extinct under an intolerable servitude. On the mainland they were exterminated in some places, and in others reduced to the condition of serfs or tributaries. The Spaniards colonized a great part of the countries which they invaded. The Spanish American colonies had for their objects both agriculture and mining. The North American colonies were the consequence of emigration, either voluntary or produced by religious persecution and civil war at home. The Puritans went to New England, the Quakers to Pennsylvania, and the Cavaliers to Virginia. They formed communities under charters from the crown, and had local legislatures, but were still subject to the sovereignty of the mother country. The mother country sent its governors, and named, either directly or indirectly, the civil functionaries. The precise amount of obedience that the colonies then owed to the mother country cannot be exactly defined. The American revolution only showed that it did not extend to a certain point, without showing how far it did extend.

A new feature has appeared in modern European colonization, that of penal colonies, which was an extension of the principle of the presidii on the coast of Barbary, already mentioned. Convicts were sent by England first to North America, and afterwards to New Holland, by France to Guiana, by Portugal to the coast of Angola, and by the Dutch to Batavia. They were either employed at the public works, or hired to settlers as servants, or were established in various places to cultivate a piece of land, for which they paid rent to the government. The policy of penal colonies has been much discussed. They may afford a relief at least temporary, but at a great cost to the mother country, by clearing it of a number of troublesome and dangerous characters, especially so long as criminal legislation and the system of prison discipline continue as imperfect as they are at present in most countries of Europe; but with regard to the convicts themselves, and the prospect of their reformation, everything must depend upon the regulations enforced in the colony by the local authorities. If we look however at the horrid places of confinement to which convicts are sent by most continental governments, and which are sinks of every kind of corruption and wretchedness, we cannot help feeling disposed to think more favourably of such colonies, under proper regulations and discipline, and to prefer the penal colonies of Great Britain to such ill-regulated places of punishment, which do not even affect to be places of reformation.

With regard to the advantages resulting from colonies to the mother country, they appear to be, the extension of trade and exchange, the consequent employment of a number of additional hands, and the giving the means of acquiring property to many who have no chance at home. Many individuals also realize fortunes in the colonies, with which they afterwards return home, and thus add to the national wealth. Much has been written upon this subject by political and economical writers, and the advantages of colonies have been exaggerated by some, and perhaps too much underrated by others. In a general point of view, as connected with the progress of mankind, a busy prosperous colony on a land formerly wild and desert is undoubtedly a cheering sight. Commercial colonies or factories are likewise useful for protecting traders in remote and half-barbarous countries. But the proper question as to the policy of colonies now is this;—should a state form colonies in its collective or sovereign capacity, or should it put obstacles in the way of its citizens forming colonies by voluntary associations, or should it favour such associations by offering facilities to them, or at least putting no obstacles in the way; and should the state allow such associations of emigrants to form such a political community as they choose? This subject is properly discussed under the head of EMIGRATION.

An account of the great modern colonies is given under the respective heads, such as BARBADOES, BRAZILS, CANADA, CAPE OF GOOD HOPE, JAMAICA, &c.

The colonies of England consist of British North America, the British West India Islands, with the Bahamas and Bermudas, and British Guiana in S. America; Sierra Leone, Cape Coast, and Cape of Good Hope in Africa; the islands of St. Helena, Mauritius, Ceylon, Pulo Penang, Sincapore, and Malacca; various settlements on the coasts of Australia, and Tasmania, or Van Diemen's Land. The vast possessions of the East India Company in India cannot be called colonies, though they are dependencies of Great Britain, by which name also Gibraltar and Malta must be designated

France has the French West India Islands, and French Guiana in America; Senegal, on the Coast of Africa; the island of Bourbon; and Pondichery, in the East Indies.

Spain has lost her vast dominions in Mexico and South America, but has retained the fine islands of Cuba and Puerto Rico: she has also the Philippine Islands.

Portugal has lost the Brazils, but has still numerous settlements on the coast of South and East Africa, at Angola, Benguela, Loango, and on the Mozambique; but these settlements are the most degenerated of all European colonies. In India the Portuguese retain Goa, and they have a factory at Macao, and a settlement on the northern part of the island of Timor.

The Dutch have the islands of Curaçao and St. Eustaz, and Surinam in Guiana. In Asia they have the great colony of Batavia with its dependencies, various settlements on the coasts of Borneo, Sumatra, Celebes, and the Molucca islands.

The Danes are possessed of the islands of St. Cruz and St. Thomas in the West Indies; Christianburg, near Accra, on the Guinea coast; and Tranquebar in the East Indies.

The Swedes have the island of St. Bartholomew in the West Indies.

A society of North American philanthropists has founded since 1821, on the Guinea coast, east of Cape Mesurado, a colony of emancipated negroes, who have been transferred thither from the United States. The colony is called Liberia, and has two small towns, Monrovia and Caldwell.

On the subject of modern colonies, Raynal, *Histoire des Etablissemens des Européens dans les deux Indes*, may be useful, though it is often exaggerated and turgid; but the best authorities are the original accounts of the various discoverers and founders of the colonies, such as have been published by Navarrete for the Spanish, Barros for the Portuguese, &c.

The *English Colonies* have, as a general rule, local legislatures, elected by the people, and a governor and council named by the king. The foreign commerce of these colonies is regulated by the sovereign authority of the mother country, and put on such a footing as generally to allow the products of the colonies admission into British ports on more favourable terms than those of other countries. To the amount of this protecting duty, the colonies then have the advantage of a monopoly in the markets of the mother country. The old strict colonial system, of excluding foreign countries from direct commercial intercourse with the colonies, had the double object in view of securing all the supposed advantages of the exchange of British for colonial products, and giving employment to the British merchant navy. The rigour of this system however has gradually relaxed, and given way to clearer views of self-interest. Still the colonial system, as maintained by Great Britain, presents in many instances examples of foreign possessions which are expensive to the country without any apparent corresponding advantages; and also of foreign possessions, the trade with which is still encumbered with regulations either unfavourable to the producers of the mother country, or favoured by discriminating duties which are an unfair tax on the domestic consumer. The expenditure in some of the colonies for the purposes of administration and protection is beyond the means of the colonial revenues to meet, and the deficiency must of course be supplied by the parent state. The immense patronage which colonial possessions put at the disposal of the government is naturally one reason why colonies are looked upon as profitable things by those who participate in the advantages of posts and places in them. On the other hand, those who only contribute to these expenses may not unreasonably ask for some proof of solid advantage to the nation in return for this annual outlay. Setting aside the interests of those concerned in the administration of the colonies, it is asked, in many cases, what advantage does the rest of the nation receive? So far as colonies may be desirable posts for protecting British commerce and shipping, the advantage of maintaining them may be fully equivalent to the expense. But in every particular instance the question as to the value of a modern colony to the mother country (omitting, as before mentioned, the value of the patronage to those who confer places in the colonies and the value of the places to those who receive them) is simply this;—what advantage is this said colony to the productive classes of the country and to those who consume the products of the colony? a question not always easy to answer; but this is the question, the solution of which must decide whether a colony ought to be maintained or not, if we look only to the interests of the mother country. If we look to the interests of the colony, it may be in many and certainly is in some cases, the interest of the colony to remain as it now is, under the protection and sovereign authority of the mother country. But again the question recurs, what is the advantage to the mother country? If some advantage cannot be shown, the maintenance of a useless colony is a pure act of national benevolence towards the colony and to those few of the mother country who have places in it. If our present relation with a colony such as Jamaica or Canada entails any expense on the mother country, we may ask whether all the commercial advantages that result from this relation would not be equally secured, if only the free commercial relation existed and that of administration were to cease. In support of this view, it is shown that the commerce of Great Britain with the United States, now free and independent, has increased most wonderfully since the separation, and probably more rapidly than it would have increased under the colonial system. This being the case, a similar increase might be anticipated in the trade with all those foreign possessions whose trade is really of any importance. This argument, to which it is difficult to reply, is met by saying that if we give up those colonies that cause expenditure on the part of the mother country, some of them at least would be a prize for other nations, who would exclude us from the commerce of those former colonies, or allow it only on unfavourable terms; or that these colonies would throw themselves into the arms of foreign nations, and the same result would follow. To this it is replied, that no other nation is in a condition to take on itself the management of expensive colonies; that nations, like individuals, will, if let alone, buy where they can buy cheapest, and sell where they can sell dearest; and that if we should be shut out from the commerce of any of our present colonies, there are equally good or better markets from which we are now in part or altogether excluded owing to those very regulations, which only exist because we have colonies to maintain.

The colonial administration of the British colonies is an important department of the general administration. At the head of it is the principal colonial secretary, who is one of the three secretaries of state, assisted by two under secretaries.

COLOQUI'NTIDA. [CUCUMIS.]

COLORA'DO, a river of Mexico, falls into the northern extremity of the Gulf of California, somewhat south of 32° N. lat. To judge from its appearance at its mouth, we should not suppose this river to have a course of 230 leagues or about 640 English miles, which Humboldt assigns to it; for it has often not more than six feet of water, and its breadth at low water is hardly more than 200 yards. Two low islands at its mouth are called, by Hardy, Montagu and Gore. Its banks here are low, but the western is somewhat higher than the eastern. About 30 miles from its mouth, Hardy found only two feet of water in the channel. Sixty miles from its mouth in a straight line, the Colorado is joined by the Rio Gila, a river which runs east and west for above 300 miles, and has its source in the Sierra Mogollon, the southern extremity of the Rocky mountains, about 34° 20′ N. lat., and 108° W. long. The place where both rivers unite has been visited by Dr. Coulter, who states that the country between the rivers, as well as on both sides of them, is a sandy desert, without potable water, and subject to excessive heat: the thermometer in one instance rose to 140°.

The remainder of the course of the Rio Colorado is entirely unknown, the country having only been visited by two monks, according to whose reports, as Humboldt tells us, the river is formed by two upper branches, the northern, Rio Zaguananas, rising in about 40° N. lat., and the southern, Rio Nabajoa, rising in about 39° N. lat. Both descend from the western declivity of the Rocky Mountains. [COLUMBIA RIVER.] These monks also report that they found on the banks of the Rio Yaquesila, a tributary of the Colorado, a nation of natives, the Moqui, far advanced in civilization. They passed there through a considerable town, which had two large squares, and a straight and wide street; the houses had several stories, and flat roofs, on which the people assembled in the evenings. The fact however seems to be very doubtful. Dr. Coulter does not mention it, though he had frequent opportunities of communicating with the American hunters, who traverse these countries in search of otters. (Humboldt, Hardy, Dr. Coulter, in *London Geogr. Journal*, vol. v.)

COLOSSE'UM. [AMPHITHEATRE.]

COLOSSIANS, EPISTLE TO THE, a canonical epistle of the New Testament, addressed by St. Paul to the Christians of Colossæ, a city of Phrygia. The date generally assigned to this epistle by the commentators and critics is A.D. 62. (*Tablettes Chronologiques*, par l'Abbé Lenglet Dufresnoy, tome ii. p. 211. Dr. Adam Clarke's *Succession of Sacred Literature*, vol. i. p. 89). Some say A.D. 63, or the 9th of Nero. In the Dissertations on the Harmony of the Gospels, by the Rev. Mr. Greswell (vol. ii. pp. 63—66), it is shown that the Epistles to the Ephesians, to the Philippians, and to Philemon, were written by St. Paul at the same time as the one to the Colossians, namely, in A.D. 60, nearly at the termination of the apostle's first imprisonment at Rome; and Epaphroditus in Philemon is considered by Mr. Greswell to be the same person as Epaphras in Colossians. From the expressions in ch. i. ver. 4, 7, 9, and ch. ii. 1, it is inferred by some that St. Paul himself was personally unknown to the Christians of Colossæ; but others, especially Dr. N. Lardner (*Credibility Gos.*), who argues on the statements of Theodoret (tom. iii. p. 342), assert that St. Paul preached and planted the church at this city. According to Eusebius, this city was one of three which, in the 10th year of Nero (that is, a year after the reception of this epistle), were totally destroyed by an earthquake. The chief object of St. Paul in this epistle appears to have been to exhort the Christians of Colossæ to adhere steadfastly to the doctrines which he taught, and to reject the opinions of the Jews and the Pagan philosophers. The concluding sentence of the fourth chapter states that the conveyance of this address was committed to Tychicus and Onesimus. For a list of published sermons on texts from Colossians, see Watt's *Biblioth. Brit.* (Eichhorn, Michaelis, Horne.)

COLOSSUS. [STATUE.]

COLOUR, in Optics. [LIGHT.]

COLSON, JOHN, born about the beginning of the eighteenth century, studied at Emmanuel College, Cambridge, and was master of the free-school at Rochester till 1739, when he succeeded Sanderson as Lucasian professor at Cambridge. He died in 1760 He is worthy to be remembered for his English edition of Newton's Fluxions, London, 1736; and his translation of the Analytical Institutions of Maria Agnesi, which lay in manuscript till 1801, when it was published by the Rev. John Hellins at the expense of Baron Maseres.

COLTSFOOT, the common name of TUSSILAGO FARFARA.

CO'LUBER, a sub-genus of Ophidians, or serpents. The genus *Coluber* of Linnæus comprised all the serpents whether venomous or not, whose scales beneath the tail are divided into two, or more properly speaking, arranged in pairs; but the term is generally applied by Cuvier and other authors to those serpents which have transverse plates on the belly, and the plates under the tail forming a double row, a flattened head with nine larger plates, teeth almost equal, and no poison-fangs.

Laurenti placed the *Colubridæ* between the rattlesnakes (*Caudisona*) and the vipers. Scopoli's genera were those of Linnæus. Lacépède placed the *Colubridæ* at the head of his nine genera of serpents, and next to them came the boas and rattlesnakes. Alexander Brongniart made them the last but one of his six genera of Ophidians, arranging them between the vipers and the boas. Latreille gave the genus a place between *Chersydrus* and *Dipsas* in his family of *Anguivipères*. Daudin comprehended 172 species under the genus. In the synoptical table of Duméril and Bibron, Cuvier is made to place it between *Dipsas* and *Cerberus*. Oppel subdivides his section (the second) the *Squammata* (Ecailleux) into seven families, of which the *Colubridæ* (Couleuvrées) are the last, coming immediately after the *Pseudo-vipères*. Merrem divided the serpents into two sub-tribes: in the first sub-division, the *innocui*, or serpents without venom, of the first tribe (*Gulones*), *Coluber* appears between *Scytale* and *Hurriah*. De Blainville separated the serpents into *Dipodes* and *Apodes*; *Coluber*, coming immediately after *Boa*, is placed in the innocuous division of these *Apodes*. Mr. Gray, in 1825, divided the Ophidians, his fourth order of reptiles, into two great groups, venomous and innocuous, and the *Colubridæ* were placed by him between the *Hydridæ* and *Böidæ*, the three families of the second group. Dr. Harlan, in the same year, made the Ophidians, his fourth order, contain six genera, and placed *Coluber* between *Ophisaurus*, his first, and *Vipera*, his third genus. Mr. Haworth, in the same year, arranged the genus between *Scytale* and *Dryinus*, among the true serpents (*Apoda epalpebrata*, or serpents without eye-lids), and under the innocuous branch of the *Gulonia*. Fitzinger (1826) placed the *Colubröides* between the *Pythonöides* and the *Bungaröides*, in his comprehensive third tribe *Monopnoa squammata*. Ritgen (1828) arranged the *Colubridæ* and the *Böidæ* under his *Macrostomata*, the third sub-partition of the first sub-division, *Holodontaspistes* (with entire teeth), of his third sub-order of scaly serpents. Wagler, whose untimely loss all zoologists deplore, published (1830) his 'Naturaliches System der Amphibean.' He makes his fourth order, the serpents, consist of one family only, comprehending ninety-seven genera, and places *Coluber* the forty-ninth between *Spilotes* (Wagler), and *Herpetodrys* (Böié). In 1831, Mr. Gray, in Griffith's 'Cuvier,' published a synopsis, in which he makes some alterations in his original classification. The *Squammata* form the second section, and the *Ophidians* its third order, which is divided into two sub-orders, the venomous and innocuous, the upper jaw of which last is toothed, but without fangs, or with very small ones: in the latter sub-order, the *Colubridæ* are again placed with the boas and the hydras.

In 1832 Professor John Müller, of Bonn, published his system: the Colubers are arranged by him immediately after *Dryinus*, as the last of the *Isodonts*, the third family of his second order, uniting the *Macrostomes* which correspond to the *Heterodermes* of Duméril.

The species of the genus as left by Cuvier, are very numerous, and their geographical distribution is very wide. The foreign species are some of them remarkable for their vivid colouring, and others for the regularity of the pattern, so to speak, with which they are marked. Others, again, are singularly slender in form, but none grow to a large size. The harmless *common snake*, or *ringed snake*, *Neidr fraith*, *Neidr y tomenydd*, of the antient British, *Natrix torquata* of Gesner and Ray, *Coluber Natrix* of Linnæus, will serve as an example of the form. [NATRIX.]

COLUMBA. [COLUMBIDÆ.]

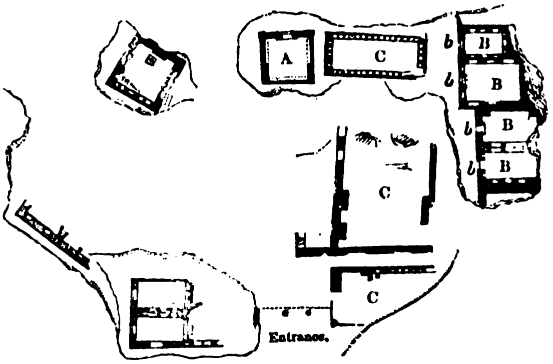
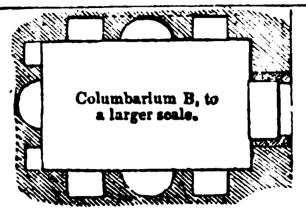
COLUMBA'RIUM, a place of sepulture used for the ashes of the Romans after the custom of burning the dead had been introduced among them. The word columbarium signifies a dovecote; and its application to the Roman places of interment has arisen from the resemblance between the small arched holes which contain the sepulchral urns and the recesses formed for the doves in a dovecote.

This application of the word columbarium is proved by antient inscriptions, but we are not aware that the term is used in this sense by any extant Latin writer.

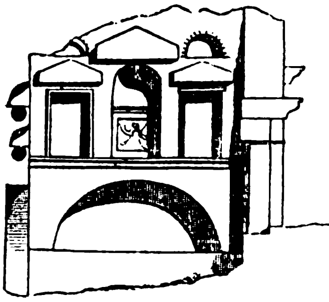
In the Villa Doria Pamfili at Rome was discovered, some years since, a very extensive columbarium, or rather an assemblage of columbaria, which are shown on the accompanying plan. It was surrounded by a wall, with a triple entrance, formed by two columns. The columbaria, which are on a very diminutive scale, are placed without any regularity. One building, A, superior in workmanship to the others, appears to have been a small temple in antis, built with red bricks, set with very delicate joints, and rubbed on the surfaces. The chambers, B, B, B, &c., were superior columbaria, with large niches, which contained double ollæ or vases for the ashes of the dead, with small tablets let into the wall below each niche. The small structures at C, C, which most resemble the dovecotes, are supposed to have been the sepulchres of the slaves. They are built with reticulated work, and are filled with rows of pigeon-holes, which contain ollæ: they have no inscriptions. The brickwork of these columbaria is of several dates, if we may judge from the diversity of construction. The chambers B *b*, B *b*, have stone doorways, in the Egyptian style. The interior of these little structures, and the temple, have been stuccoed and ornamented with reliefs, and painted. The small room V, in the British Museum (Townley Marbles), represents a columbarium on a large scale: the niches are represented with sculptured and plain tablets. In the immediate neighbourhood of the Columbarium, in the Villa Doria Pamfili, are numerous in[illegible]tions, tablets, and monumental urns, which belonged to these sepulchres, but having been removed from the ollæ, they lose part of their interest. There are several columbaria in the neighbourhood of Rome, among which that of the family Pompeia is remarkable for its tablets, urns, &c., some account of which is given in the *Encyclopédie Méthodique, Architecture*. A sepulchral chamber was discovered in the year 1746 near the gate of San Sebastian at Rome. (See plates to Moses's 'Classical Ornaments, Vases, Candelabra,' &c.)

[Plan of Columbaria, discovered a few years since in the gardens of the Villa Doria Pamfili at Rome.]





Columbarium B, to a larger scale.



[Section of Columbarium B.]

COLUMBIA, DISTRICT OF, lies on both sides of the Potomac, and is bounded by the State of Maryland on the north-east, north-west, and south-east, and by the State of Virginia on the west and south-west. It forms a square of 100 square miles. That part of it which lies on the south side of the Potomac was ceded by the State of Virginia, and that which is on the north side of the same river, by the State of Maryland, to the United States, July 16, 1790, when it had been determined to establish the seat of the Federal Government on the banks of the Potomac. Washington became the seat of the Federal Government in 1800. The Potomac traverses the district in a south-east direction, and receives within it a small stream called the Eastern Branch. By the junction of this stream with the Potomac a spacious harbour is formed, with sufficient water for the largest vessels. The tides of the Atlantic ascend as far as Georgetown in the district.

The surface of the district is diversified by slight elevations: the soil is rather light and poor. The three towns which it contains are Alexandria on the Virginia side of the river, Washington, the seat of the general government, and Georgetown. The Virginia part, which contains about thirty-six square miles, forms the county of Alexandria, and the Maryland part forms the county of Washington.

This district is immediately and exclusively subject to the Congress of the United States. By Act of Congress, February 27, 1801, the laws of Virginia and Maryland prevail in the parts which were respectively ceded by these States.

Alexandria, Washington, and Georgetown, are under the immediate government of their several corporations, which however, as already stated, are subject to the control of the Congress of the United States. The inhabitants of this district are not represented in Congress. The object in forming this district was to secure the functionaries of the Federal Government from the local jurisdiction of any single state, and all collision with its authorities.

In 1820, the population of the district was 22,615 whites, 4048 free coloured, 6376 slaves, total 33,039: in 1830, the numbers were whites, 27,635; free coloured, 6150; slaves, 6119; total, 39,904. The shipping of the district is about 17,500 tons. The capital, Washington, is in 39° 53′ 30″ N. lat., and about 76° 55′ 30″ W. long. from Greenwich.

COLUMBIA. [CAROLINA, SOUTH.]

COLUMBIA RIVER, is the largest of the American rivers which fall into the Pacific, running probably 200 miles more than the Rio Colorado, whose course is estimated by Humboldt at about 640 miles. Its numerous upper branches rise in the Rocky Mountains, between 42° and 54° N. lat., and are at their source about 650 miles from the Pacific, in a straight line. The principal branch rises in a lake, near 50° N. lat., and runs first in a north-north-western direction along the base of the Rocky Mountains; but in the neighbourhood of Mount Brown (near 52° N. lat.) it suddenly turns to the south, and continues in that direction through more than three degrees of latitude, till it meets another of its great branches, the river Clarke, which also rises in the Rocky Mountains, near 45° N. lat., and traverses more than three degrees of latitude in a north-western direction. At the point of junction the Columbia turns to the west, but by degrees declines again to the south, so that at its junction with the river Lewis or Saptin it has a complete southern course. The river Lewis rises also in the Rocky Mountains, near 42° N. lat., and runs first to the west, then to the north, and towards its mouth again to the west. Though its course is long, it is much inferior in magnitude to the Columbia at their junction, the width of the latter being 960 yards, while that of the Lewis is only 575 yards. Between the mouths of the Clarke River and the Lewis occur the greatest impediments to navigation. Not far below the mouth of the Clarke River are the Kettle Falls, 21 feet high; and above that of the Lewis are other cataracts, where the descent in 1200 yards is 37 feet 8 inches, and where the rapids extend from three to four miles. The river is here contracted to 45 yards in width. After its junction with the river Lewis, the Columbia still runs upwards of 300 miles, first for a short distance south, and afterwards in general in a western direction. In this part it is from one to three miles wide, embracing a number of islands, some of which are of considerable extent. It empties itself into the Pacific, a little north of 46°, and the tide ascends nearly 180 miles above its mouth. The Indian name of the river is Oregon. It appears, from the most recent information, that the head waters of one branch of the Columbia, of the Colorado, and of the Platte and Yellow Stone, both branches of the Missouri, rise within a few miles of one another. (Lewis and Clarke; *Map of the Society for the Diffusion of Useful Knowledge.*)

COLUM'BIDÆ, pigeon tribe, a natural family of birds, comprising the pigeons, doves, and turtles.

Natural History.—Aristotle mentions five, if not six, birds of this group—Περιστερὰ, Πελειάς, Φάττα,* Οἰνάς, and Τρυγών, Peristera, Peleias, Phatta, Œnas, and Trugōn—entering at large into their organization and habits. (*Hist.*, book i. c. 1; book ii. c. 15, 17; book iii. c. 1; book v. c. 13; book vi. c. 1, 2, 4, and 8; book viii. c. 3; book ix. c. 7.) He also (book viii. c. 3) speaks of a bird named Φάψ (Phaps), which Athenæus (Deipn., book ix. c. 11) and others consider to be one of the *Columbidæ*, while others again hold a different opinion, inasmuch as Athenæus states that Aristotle has distinguished five species of pigeons, and enumerates Φάψ as one, omitting Πελειάς; and so Aristotle does (book viii, c. 3), but he mentions Πελειάς elsewhere (book viii. c. 13), and it is clear to us from the context that *Phaps* signified one of the *Columbidæ*, Περιστεροειδεῖς. There is considerable doubt as to which of the species of pigeons Aristotle intended to designate by the terms above given, and some of them have been applied by modern ornithologists to signify forms which he probably never saw. Only two, or at most three, can be identified with anything like certainty. Pliny (*Nat. Hist.*, book x. c. 34) writes de Columbis, and (c. 35) de Palumbibus. He enters, moreover, largely into their habits in other parts of his 'Natural History.'

Much doubt seems to have prevailed as to the proper place of the pigeons in the system. Belon collected the few species known to him under the title Ramiers, Tourterelles, Bisets, Pigeons Fuyards, and Pigeons, among the birds 'qu'on trouve viander indifféremment en tous lieux,' placing them between the Torcou (*Jynx Torquilla*, Wryneck) and the *Merle bleu*, blue thrush. Gesner arranged them between the gallinaceous birds and the bustards; Aldrovandi placed them between the domestic cock and the sparrow; Willughby between the bustards and thrushes, and Ray gave them the same place. Brisson, Pennant, and Latham insulated them in a particular order. Pennant also arranged them between the Gallinaceous and Passerine birds, and Latham between the *Passeres* and the *Gallinæ*. Other authors placed them among the Gallinaceous birds. Linnæus made them a genus of his order Passeres, arranging them between *Tetrao* (the grouse and partridges, &c.) and *Alauda* (the larks). Cuvier placed them among the Gallinaceous birds, next to the Tinamous (*Tinamus*, Latham, *Crypturus*, Illiger), making them the last of the order. In his arrangement, the Echassiers (*Grallatores*, wading birds) form the order which immediately follows the Gallinacés. Lacépède had previously given them the first place in the last-mentioned family, as did also Duméril. Meyer had insulated them as his seventh order, coming between the *Chelidones* (swallow tribe) and his eighth order, *Gallinæ*; and Illiger had found a situation for them under his *Rasores* (the Rasorial birds). Le Vaillant, who seems to have been the first who separated the *Columbidæ* into well-defined divisions, arranged them in three sections; the first containing the *Colombes*, *Ramiers*, and *Tourterelles*; the second, the *Colombars*; and the third, the *Colombi-gallines*. Vieillot made them the last family but one (*Colombins*) of his second tribe (*Anisodactyli*), arranging them between his *Ophiophages* and *Alectrides*. M. Temminck classed them as his ninth order between the *Chelidons* and the *Gallinacés*. De Blainville's order *Sponsores* or *les Colombins* contained these birds, and came between the *Saltatores* (Passeres) and the *Gradatores* (pheasants or partridges): in his amended method, as developed by M. Lherminier, they occupy nearly the same position between the Passeres and the Gallinaceous birds. C. Bonaparte (prince of Musignano) assigns the same place to them. (*Specchio comparativo.*)

When he wrote the article *Pigeon* in the 'Dictionnaire d'Histoire Naturelle,' M. Vieillot conformed to the opinion of Linnæus in placing these birds among the Passeres, because of its natural great analogy to the last-mentioned group, like nearly the whole of which the pigeons pair in the season of love, the male and female working jointly at the nest, taking their turns during incubation, and participating in the care of the young, which, among the true pigeons, are hatched blind, fed in the nest, which they do not quit till they are covered with feathers, and are supported by their parents some time after their departure from it, having no power to feed themselves. Such are the points of resemblance. Their dissimilarity consists in their mode of drinking and feeding their young, in the nature of their plumage, and the singularity of their courtship and of their voice, points of difference which also separate them from the true Gallinaceous birds, with which, says M. Vieillot, they have no analogy in their instincts, their habits, or their loves. Nearly all the Gallinaceous birds are polygamous, and lay a great number of eggs each time they incubate, which is rarely more than once a year in the temperate zones; while the true pigeons lay only two eggs each time, incubate frequently during the year, and are monogamous. Among the Gallinaceous birds, as a general rule, the male does not solace the female at the time of building the nest and of incubation; the young run as soon almost as they are out of the egg-shell, quitting their nest, and seeking their own food immediately. Finally, a striking character removes the pigeons from the Gallinaceous birds, and in M. Vieillot's opinion places them in the same natural group with the Passeres, namely, the possession of a posterior toe articulated at the bottom of the tarsus, upon the same plane as the anterior toes, touching the ground throughout its length in walking and embracing the roost in perching. On the contrary, in the Gallinaceous birds, the hind toe is articulated upon the tarsus higher than the others, and only touches the ground with its claw, or at most with its first phalanx, and remains perpendicular when the bird is on the perch. Nevertheless it must be confessed that there are found among the pigeons, species which participate in some degree with the Gallinaceous birds in regard to their manners and gait (allures) or some exterior conformity. Such are the *Colombi-gallines*, the *Pigeon-caille* of le Vaillant, to which must be added the *Colombi-gallines* of M. Temminck, the *Mountain partridge* of Sloane, the *blue-headed pigeon*, the *Cocotzin*, &c., all which have their feet more elongated than those of their congeners, with the wings of the partridges, that is to say rounded, and with the two first quills shorter than the third or fourth; but for the rest, all, with the exception of the *Colombe-galline* of le Vaillant, approach the other pigeons in their amours, their laying, and the bringing up of their young; and so it is of the birds which at Guadaloupe and Martinique bear the name of partridge; and M. Vieillot quotes Dutertre, who says that 'according to the common opinion of the inhabitants of Guadaloupe, there are three sorts of partridges, red, black, and grey, which have never passed in my mind for aught but turtles (tourterelles); for they have not the short quality of flesh belonging to our partridges, they have the straight bill, they perch and build their nests in trees, they only lay two eggs,' &c. (*Hist. des Antilles*, tom. ii.) These facts, adds M. Vieillot, have been confirmed to me by the inhabitants of Martinique and Guadaloupe. Of all the pigeons and turtles, continues this ornithologist, which I have had occasion to study in the living state, the Cocotzins are those which appear to me to have the greatest relation to the partridges: their haunt is always in the fields and savannahs; there they seek their food, and never resort to trees; they raise themselves into the air like the partridges, and after a short flight alight upon the ground. For this reason the English and the inhabitants of the United States call it the *Ground Dove*. But the habit of frequenting the ground, &c. does not belong exclusively to the pigeons whose wings are formed as above stated, for, according to Latham, the *Columba Chalcoptera* (Phaps), which M. Temminck arranges with his *Columbæ* (Vieillot's first section), has the same habits, so that the English of New Holland call it the *Ground Pigeon*. (Vieillot.)

'The family of Columbidæ (Mr. Vigors, *Linn. Trans.*, vol. xiv. p. 410) alternately arranged by systematic writers among the *perching* and *gallinaceous* orders, and not unfrequently grouped as a separate order between the two, at once indicates where the point of junction exists between them. These birds, although we have the high authority of Linnæus for uniting them with that division of our *perchers* which forms his *Passeres*, I do not hesitate in arranging, conformably to the opinion of M.M. Cuvier and Illiger, as a subdivision of the *gallinaceous birds*.

---

* Belon says that the modern Greeks call it Phassa

'In those particulars, where they respectively assume the character of each order, their affinity with the latter is considerably stronger than that which approximates them to the former. Their food and habits, their internal economy, and the formation of their bills, identify them with the *Rasores;* while, on the other hand, the characters which bring them near the *Insessores*, their divided toes and comparatively short legs, are weakened by the resemblance which those members bear to the same parts of the contiguous order in their general structure, and more particularly in the bluntness of the nails, so strongly indicative of the rasorial habits of the *Gallinaceous* tribes, and so strikingly contrasted with the sharpness of the nails in the Linnæan *Passeres*. They are much more nearly allied to these latter tribes by their habits of perching and building their nests in trees or rocks, by the absence of the spur on the legs of the male, and by the inferior number of their tail-feathers.'

In a note to that part of the text which alludes to the rasorial habits of the *Gallinaceous* birds, the author cites the habits of *Columba Nicobarica*, *Columba carunculata*, and *Columba passerina*. Mr. Vigors accordingly places the *Columbidæ* in the aberrant group of his *Rasores*. 'I have already observed, when speaking of the affinities,' says that ornithologist in the paper above quoted, 'which connect the orders of birds together, that the Columbidæ form the passage from the *Insessores* to the *Rasores* by their habits of perching and their powers of flight. The hind-toe is articulated, as in the *Perchers*, and their *tarsi* are shorter, more particularly in the earlier groups, than those of the *Gallinaceous Birds* in general. The first group which we meet in this extensive family is the genus *Vinago* of M. Cuvier, the bills of which, stronger and more solid than they are usually found to be among the pigeons, unite them to *Penelope* and *Crax*, which form the opposite extreme of the present order, as well as to *Musophaga* and *Corythaix*, which approach, as we have seen, the whole of the groups before us, and connect them with the *Perchers*. From this genus *Vinago*, which seems confined to the southern divisions of the Old World, we may observe a series of groups leading gradually to the true *Columba*, of which genus the European species *Columba Œnas*, Linn., may be considered to form the type. Hence we are led by several intervening species to the *Columbi-Gallines* of M. Le Vaillant, which, still retaining the soft and flexible bill of *Columba*, approach the typical Gallinaceous birds in their more elevated *tarsi*, and in their habits of living in company and seeking their nourishment chiefly on the ground. Among these may be noticed some forms, *C. Nicobarica*, Linn., and *C. carunculata*, Temm., for instance, which possess the feathered appendages, together with the naked face and caruncles of the Linnæan *Gallinæ;* and another group, the *Lophyrus* of M. Vieillot, which exhibits the size and general form of the same birds, as well as the singular plumes which frequently decorate their head. This last-mentioned genus, formed of the crowned pigeon of India, possessing the strongly-formed leg and foot of *Meleagris*, Linn., but without the spurs, while at the same time it retains the bill of *Columba*, may be observed to open the passage immediately from the present to the succeeding family' (the Phasianidæ). Read 3rd December, 1823.

In 1825 Mr. Swainson wrote as follows upon this interesting family:—'The extensive genus of *Columba*, like that of *Falco*, has been pronounced *indivisible* by an eminent ornithologist of the present day; who, from having made these birds his peculiar study, is in one sense pre-eminently qualified to give a decided opinion. The principle he has laid down, and on which this opinion consequently is founded, is, that whenever intermediate species are discovered which serve to unite two neighbouring genera, such genera should invariably be united.' After stating that this theory has been refuted in the pages of the 'Zoological Journal,' Mr. Swainson thus continues: 'It is admitted that there are certain peculiarities of form and of economy among the *Columbidæ*, which point out natural divisions. Some of these have been used for the construction of genera, by MM. le Vaillant, Vieillot, and Cuvier, and of sections by M. Temminck; but the immense number of species already known, and the great influx of new ones, renders it essential that many others should be formed. As we labour under a comparative ignorance of the natural economy of the vast number of tropical species recently described, any attempt to throw the *Columbidæ* into their natural arrangement must be very imperfect. The basis of such a work must rest on their natural habits, their food, and their geographic distribution. Yet, as we see in other natural families that a peculiarity of economy is almost invariably accompanied by some corresponding modification of structure, we shall receive considerable assistance by accurately examining such variations. We may note the forms, without being acquainted with their reference to the peculiar habits of the group; and although our inference in some cases may be erroneous, in others we shall not be far from the truth. The passenger-pigeons, for instance, have their first quill-feather as long as any of the others—a sure indication of that rapid and long-continued power of flight they are known to possess. The *Columbi-Gallines* of M. Le Vaillant are described as having naked and somewhat lengthened tarsi; a structure well adapted to those ambulating habits which bring some of them close to the *Phasianidæ*, Vigors, and others to the *Cracidæ*, Vigors. Another group, the *Colombars* of M. le Vaillant (*Vinago*, Cuv., *Tréron*, Vieill.), have a strong hard bill; and their short clasping tarsi covered with feathers lead us to conclude they seldom perch upon the ground; in fact, MM. le Vaillant and Cuvier both assert that these birds are only found in the tropical forests of the Old World. Apparently confined to the same regions, we see another group, wherein the bill partakes of that weak structure observed in the generality of pigeons, while the tarsi are thickly clothed with feathers, similar to the group last mentioned. These seem to be the principal divisions among the *Columbidæ*. Minor distinctions may be founded on the relative strength and structure of the quill feathers, which in some are very peculiar, and, as being connected with the powers of locomotion, deserve our attention. Some writers have attached more importance to the form of the tail, and have therefore divided the *Columbidæ* into two great divisions, separating such species as have this organ rounded or lengthened from those in which the tail is short and even. This plan, however it may help to discover a *species*, is obviously artificial, and totally inadequate to give us any ideas on natural groups. The tail in fact is but an accessory help to the wings, and therefore deserves an inferior consideration, although its form may be usefully employed in sectional divisions. Among the characters which may perhaps guide us in distinguishing inferior groups or at least sections, may be noticed the naked orbits so conspicuous in several exotic species. The ground doves of the New World show a peculiar character in having the sides of their tarsi margined by a row of minute feathers, which often conceal the knees. Their first quill feather is also very broad, and almost as long as any of the others; if these characters hold good in more instances than those I have quoted, we shall be justified in using them in a generic sense, by separating these birds from the *Columbi-gallines* of M. le Vaillant. Allied to the ground doves in manners, but greatly distinguished from them in the structure of their feet, is the bronze-winged pigeon of Australasia (*Columba chalcoptera*, Lath.). In this the front scales of the tarsi (unlike any other species I have yet seen) are formed of two series, while those of the sides are reticulated and very minute; the hind toe (or hallux) is also remarkably short, and clearly evinces an approximation to the more perfect *Gallinaceæ*.' Mr. Swainson then defines his genns *Ptilinopus*[*]. In 1827 the same author characterized the genera *Peristera*, *Chamepelia*[†], and *Ectopistes*[‡]; and in the *Fauna Boreali-Americana*[§], under *Columba Ectopistes migratoria*, he has the following note: 'As ornithologists do not appear to be aware of the great difference which exists in the groups of this family in the relative structure of their feet, we shall here draw their attention to the principal groups. In the even-tailed wood pigeons of Europe, North America, and the Old World, forming the restricted genus *Columba*, the external and internal anterior toes are equal. In the lovely genus *Ptilinopus*, Swainson, confined to the green pigeons of the Indian and Australian isles, and in that of *Vinago*, Cuv., formed by the thick-billed species of the same countries, the inner toe is much *shorter* than the outer; but in the sub-genus (?) *Ectopistes*, Swainson, and the small turtle doves, this proportion is reversed, the *inner* toe being the longest. In the beautiful genus *Peristera*, Swainson, which comprises all the bronze-winged pigeons of Australia and the ground pigeons of America, the tarsi are more elevated, the hind toe shorter, and the inner toe is likewise the longest. We have been for some time engaged in analyzing this family, with the view of ascertaining the relative value of all these groups.' Dr. Ritgen (1828) makes the genus *Columba*, Linn., form the third family (*Herpochoropteni*) of his first tribe (*Choropteni*) of his second series (*Xerornithes*, or birds of the dry land) in his trichotomous system, as applied to birds.

[§] Part II., the Birds, 1831.

P. J. Selby, Esq., in the 'Naturalist's Library' (1835), characterizes the following genera, *Carpophaga*, *Phaps*, and *Geophilus*. He thus speaks of the classification: 'Of the sub-families or five typical forms of the *Columbidæ*, we can only speak with diffidence and uncertainty, as no analysis of the species sufficiently strict or extensive has hitherto been instituted, from whence conclusive deductions can be drawn. We shall only cursorily observe, that the arboreal pigeons, embracing *Vinago*, Swainson's genus *Ptilinopus*, our genus *Carpophaga*, and some other undefined groups, with feet formed expressly for perching and grasping, and through which, from their habits and form, the necessary connexion with the insessorial order is supported, are likely to constitute one; the true pigeons, of which our ring pigeon and common pigeon may be considered typical, a second; the turtles and their allies, with feet of different proportions from the preceding, and graduated tails, a third; the ground pigeons, or *Columbi-gallines* of the French naturalists, a fourth; and the fifth is not unlikely to be represented by Vieillot's genus *Lophyrus*, in which the deviation from the proper Columbine form is not to that of the typical *Rasores*, but to the *Cracidæ*, placed at the farther extremity, and, like the *Columbidæ*, another aberrant family of the Rasorial order [*].'

Organization.—One part of the internal organization of the pigeon is worthy of special notice. The crop in the state which is adapted for ordinary digestion is thin and membranous, and the internal surface is smooth; but by the time the young are about to be hatched, the whole, except that part which lies on the trachea, becomes thicker and puts on a glandular appearance, having its internal surface very irregular. In this organ it is that the food is elaborated by the parents before it is conveyed to the young; for a milky fluid of a greyish colour is secreted and poured into the crop among the grain or seeds undergoing digestion, and a quality of food suited to the nestling is thus produced. The fluid coagulates with acids and forms curd, and the apparatus forms, among the birds, the nearest approach to the mammæ of the warm-blooded animals [†]: hence no doubt the term pigeon's milk. The number of vertebræ amounts to 13 cervical, 7 dorsal, 13 sacral, and 7 caudal = 40 (Cuvier). The sternum is narrow with a deep keel, the inferior border convex, and the anterior one curved forwards, thin and trenchant; the manubrial process is strong and bifurcated, the costal processes short. The posterior margin is cleft by two fissures on either side of the mesial plane, the lateral and superior fissures being the deepest; the mesial ones are occasionally converted into a foramen. The costal surface of the lateral margin is, as in the gallinaceous birds, of very little extent. In the crown pigeon the superior fissures are so deep and wide as to convert the rest of the lateral margin into a mere flattened process, which is dilated at the extremity. (Owen.)

Geographical Distribution.—Very extensive, the form occurring almost everywhere, except within the frigid zones. Species most abundant in Southern Asia and the Great Indian Archipelago.

COLUMBIDÆ.

Bill moderate, compressed, covered at the base of the upper mandible with a soft skin, in which the nostrils are pierced, and more or less curved at the point. Feet with three divided toes in front, and one behind.

Genera. Vinago (Cuvier).

Bill comparatively large, strong, thick, and solid, compressed at the sides; the tip very hard, hooked, and inflated; the nostrils comparatively exposed, and with the swollen or projecting membrane but little developed. Tarsi short, partly clothed with feathers below the tarsal joint; sole wide, the membrane being extended, and the whole foot formed for perching and grasping; the outer toe longer than the inner, claws strong, sharp, and semicircular, 'closely resembling in form those of the woodpecker or other Scansorial birds' (Selby). Wings of mean length, strong and pointed, second and third quills about equal and the longest in the wing. Mr. Selby says, that in all the species submitted to examination, the third quill has the central part of the inner web deeply notched, as if a piece had been cut out; and that the prevailing colours are green and yellow of different intensities, contrasted more or less in certain parts with rich purple and reddish brown.

Geographical Distribution.—Intertropical Asia[*] and Africa.

Food.—Berries and fruits.

Habits.—The genus is shy and timid, and inhabits the woods. Mr. Selby gives the following on the authority of Mr. Neill, who, speaking of *Vinago sphenura*, says, 'I had two, but both I believe were males. Both had a *song*, very different from the mere cooing of the ringdove. When they sang in concert they gave the same little tune, but on different keys. After the death of one the survivor used to sing at command, or, at all events, when incited to it by beginning its tune.[†]'

Example.—*Vinago aromatica*, *Columba aromatica*, Latham. 'The Aromatic Vinago is of a mild and timorous disposition, and is generally seen in flocks or societies, except during the period of reproduction, when they pair, and retire to the recesses of the forest. The nest is simple, and composed of a few twigs loosely put together, and the eggs are two. . . . The base or softer part of the bill is a blackish-grey, the tip yellowish-white, strong, much hooked, and bulging on the side. The forehead is of a bright siskin green, the crown greenish-grey, the chin and throat gamboge-yellow, the remainder of the neck, the breast, belly, lower back and rump, yellowish-green. The upper back or mantle, and a part of the lesser wing coverts, are of a rich brownish red, and exhibit a purplish tinge in certain lights. The greater wing-coverts and secondary quills are greenish-black, with a deep and well-defined edging of gamboge-yellow throughout their length. The tail has the two middle feathers wholly green, and slightly exceeding the rest in length; these are of a dark blueish-grey, with a

[†] Mr. Gould has figured Vinago Sphenura, N.S., from the Himalaya mountains, in his beautiful 'Century of Birds.'

dark central band. The under tail-coverts are yellowish-white, barred with green. The legs and toes are red, the claws pale grey, strong, sharp, and semicircular.' (Selby, and see Temminck.)

Locality.—The continent of India, Java, and other adjacent islands.

Habits.—Arboreal. Mr. Selby, in the interesting work above quoted, gives the following note which accompanied the skins of *Vinago militaris*, and *Vinago aromatica.* 'Green Pigeon.—This beautiful bird has brilliant red eyes. Its feet are something like the parrot's, and it climbs in the same way as that bird. It is very difficult to find; for although a flock is marked into a tree, yet its colour is so similar to the leaf of the banyan (on the small red fig of which it feeds), that if a bird does not move you may look for many minutes before you can see one, although there may be fifty in the tree.'

Ptilinopus (Swainson.)

Wings moderate, first quill contracted towards the apex, third and fourth longest. Bill slender. Tarsi feathered.

Mr. Swainson says that in proposing the characters of this genus, he wishes them to be considered more as indicating a group, by which the genus *Tréron*, Viell., (*Vinago*, Cuv.), may be united to the naked-legged pigeons, than as being so rigidly framed as to exclude all other species which do not strictly present the same structure. 'It is quite evident,' continues Mr. Swainson, 'from consulting the excellent figures of MM. le Vaillant and Temminck, that there are a number of pigeons found both in India and Australasia, which have the feathered tarsi of *Tréron*, accompanied by the slender bill of the other *Columbidæ*, and thereby clearly indicate an intervening group: yet among these birds there is a material difference in the construction of their quill feathers. In the *Columba magnifica*, for instance, the first quill is equal in breadth to any of the others, and thus assimilates, probably, to that structure which belongs to *Tréron* (I say probably, because I have not, at this moment, the means of ascertaining the fact. Mr. Vigors is in possession of several specimens of this group, which he assures me have no peculiarity in the shape of the first quill feather), while in the bird we are about to describe, this quill is suddenly narrowed, and resembles the blade of an obtuse pen-knife. This singular formation, however, I have detected in several of the naked-legged pigeons, such as the *Col. striata*, Lath., and the *Col. humeralis* of Temminck, two birds from Australasia in the Linnæan Society's collection; and likewise in two other species from Brazil now before me. This character, therefore, will not be peculiar to *Ptilinopus;* but when coupled with the feathered tarsi and slender bill, may indicate a group to which the *Col. Monacha* of Temminck, and the *Colombe porphyre*, most probably belong. The *Columba magnifica* may thus form the type of a subordinate section, more closely approaching to *Tréron;* while the narrow quill-feather of *Ptilinopus* may serve to conduct us to the naked-legged pigeons*. In the first volume of 'The Natural History and Classification of Birds†,' the same author says, 'Sometimes one half or more of some of the quills are (is) of the usual breadth, while their terminating end is suddenly contracted and obtusely pointed: this formation is seen in some few species of the exotic pigeons belonging to the genus *Peristera* and *Ptilinopus*. It cannot, however, as some have imagined, be taken as a subgeneric character, because perhaps the next species in the series has it not; and it is probably only a sexual distinction.' (p. 96.) Mr. Selby, in 'The Naturalist's Library‡,' feels inclined to still further subdivide the group, restricting the genuine title of *Ptilinopus* to that group of smaller pigeons in which the first quill feather becomes suddenly narrowed or attenuated towards the tip, and the tarsi are feathered almost to the division of the toes.

Habits and Food.—Geographical distribution of the restricted genus.—The Moluccas, the Celebes, and the islands of the Pacific (Selby.) Habits retired; in forest solitudes. Food, fruits and berries.

Description of the restricted genus.—Bill comparatively slender, the base slightly depressed, and the soft covering of the nostrils not much arched or swollen; the tip, though hard, is little inflated, with a gentle curvature; the forehead is rather low and depressed; the legs are short but strong; the tarsi clothed with feathers nearly to the division of the toes; the feet are calculated for grasping, and are similar in form to those of *Vinago*, the sides of the toes being enlarged by the extension of the lateral membrane, and the outer longer than the inner one; the wings are strong and of moderate length, the first quill feather considerably shorter than the second, and suddenly narrowed towards the tip, a peculiarity also possessed by several pigeons belonging to other distinct groups, and by which means the connexion is thus kept up between them. The third and fourth quills are nearly equal to each other, and are the longest in the wing. The tail is of proportionate length, and generally square at the end. Predominating colour like that of *Vinago*, green, varied in parts with yellow and orange, and in some, beautifully encircled with masses of purplish red and vivid blue. (Selby.)

Example.—Ptilinopus cyano-virens, *Columba cyanovirens* of Lesson, who described it in the 'Voyage de la Coquille.' The bird is termed *Manasope* in the Papuan tongue, and inhabits, says Lesson, the profound and still virgin forests (encore vierges) of New Guinea. It was in the neighbourhood of the harbour of Doréry that we procured the greatest number of individuals. Their low cooing was heard frequently from the large trees, and every thing indicated that they were common.

Description.—Total length from the end of the bill to the extremity of the tail, eight inches six lines (French): bill delicate and black; iris of a red brown; tarsi short, and nearly entirely feathered; toes with a membranous border, and of a lively orange colour; head, rump, upper part of the body, wings and tail, of an agreeable grass-green; a large patch (calotte) of a beautiful indigo blue covers the occiput; elongated blue spots occupy the centre of the subalar feathers, which are bordered with a straight yellow line; the internal and hidden part of the same feathers is brown; the quills are entirely brown, and bordered at the external edge with a line of canary yellow; the tail is square and rectilinear; the feathers which compose it are fourteen in number, brown, their extremities white below, and of a green similar to that of the back above, passing into black in the middle, and each terminating within with a white spot; the two exterior ones are brown, bordered with yellow externally, as are the two or three next; the shaft is brown; the throat to half-way down the neck is ash-grey; the breast is greyish-green; the belly and the flanks are at first green mingled with some yellow borderings, and then comes a large patch of yellowish-white extending on each side so as to form a kind of girdle; the feathers of the thighs are green; those of the vent, white and pale yellow; the lower tail coverts are yellow mingled with green. M. Lesson mentions another individual rather smaller, with some differences of plumage, which he supposes to have been either a female or a young one. Mr. Selby remarks upon the fact that no notice is taken of the form of the first quill feather in this description, and regrets it, but entertains little or no doubt of its presence in nearly a similar form to that assumed by the rest of this group, of which *Ptilinopus purpuratus* is the type. *Locality*, New Guinea.

[Ptilinopus cyano-virens.]

---

* 'Zoological Journal,' vol. i. p. 473. † 'Cabinet Cyclopædia,' 1836.
‡ 'Ornithology,' vol. v. p. 100.

Carpophaga (Selby).

'In this group,' says Mr. Selby, 'which is composed of birds of a much larger size than the preceding, the wings, though possessing the same relative proportions, have no emargination, or sudden narrowing of the tip of the first quill. Their tarsi also are not so thickly or entirely feathered; and their nostrils are placed nearer to the base of the bill. In some species, green, yellow, and purple are the prevailing colours; in others, a rich bronzed or metallic colour composes the upper plumage, exhibiting shades of deep green and purple, according to the light in which it is viewed, while in those which lead the way to the typical pigeons, the tints become less vivid and more uniform in their distribution. Their bill is considerably depressed at the base, the membrane in which the nostrils are placed but little prominent or swollen, the tip compressed and moderately arched, the tomia slightly sinuated. The forehead is low, and the feathers advance considerably upon the soft portion of the bill. In many of them a caruncle, or gristly knob, varying in size and shape according to the species, grows upon the basal part of the upper mandible during the season of propagation. This is supposed to be common to both sexes, as the female is described with it in Duperrey's 'Voyage.' After this epoch it is rapidly absorbed, and its situation scarcely to be observed upon the surface of the bill. The feet are powerful, and formed for grasping, the soles being flat and greatly extended. As in the other members of this group, the hind toe is fully developed and long, and the exterior longer than the inner toe. They inhabit the forests of India, the Moluccas, Celebes, Australia, and the Pacific Isles. Their food consists of fruits and berries. That of the precious nutmeg, or rather its soft covering, known to us by the name of mace, at certain seasons affords a favourable repast to some species, and upon this luxurious diet they become so loaded with fat as frequently, when shot, to burst asunder when they fall to the ground. And here we may remark on the remarkable provision Nature has made for the propagation as well as the dissemination of this valuable spice, for the nutmeg itself, which is generally swallowed with the whole of its pulpy covering, passes uninjured through the digestive organs of the bird, and is thus dispersed throughout the group of the Moluccas and other islands of the east. Indeed, from repeated experiments, it appears that an artificial preparation analogous to that which it undergoes in its passage through the bird, is necessary to ensure the growth and fertility of the nut; and it was not till after many unsuccessful attempts had been made that a lixivium of lime, in which the nuts were steeped for a certain time, was found to have the wished-for effect, and to induce the germinating tendency. The fruit of the Banyan (*Ficus religiosus* (religiosa), the sacred tree of the Hindoos, is also a favourite repast of all the pigeons of this group, as well as o the stronger-billed *Vinago*.'

Example.—Carpophaga oceanica, Columba oceanica, Lesson. This species, according to Lesson, is the *Moulouesse*, or *mouleux*, of the natives of Oualan, and though it approaches the Nutmeg Pigeon, *Columba* (*Carpophaga*) *ænea* very nearly, it differs from it in size, being one third less, and in the distribution of some of its colours. 'The Nutmeg Pigeon lives more particularly in the eastern Moluccas, and especially at New Guinea and Waigiou, while the Oceanic Fruit-Pigeon is abundant in the little isle of Oualan, in the midst of the great archipelago of the Carolines, and seems to exist in the Pelew Islands, where Wilson mentions it under the name of *cyep*.' Lesson further observes, that it may be possibly spread over the Philippines, and at Magindanao.

Description.—Total length, fourteen inches (French), including the tail, which measures five; the bill, an inch long, is black, strong, and surmounted at its base by a rounded and very black caruncle; the feet are very strong and of a bright orange colour; the tarsi are feathered nearly down to the toes, which have a well-developed border; the wings are pointed, and only one inch shorter than the tail, which is almost rectilinear. The feathers of the forehead, cheeks and throat, are whitish mixed with grey; the head and the back of the neck are of a deep slaty grey; the back, rump, wing-coverts, quills, and tail feathers, are of a uniform metallic green, passing into brown on the interior of the great feathers; the breast and upper part of the belly are grey, with a tint of rust colour; the lower part of the belly, the vent, the thighs, and the lower tail-coverts, are a deep ferruginous red; the tail-feathers on the under side are a bright reddish green (vert rougeâtre clair.) (Lesson).

M. Lesson thinks that this, very probably, is the species mentioned by 'the celebrated naturalist, Forster (and not Captain Forster, as the reading is, twice, in M. Temminck's work, tom. i. p. 89, 8vo), who observed in the Isle of Tanna, one of the New Hebrides (Cook's 'Second Voyage,' vol. iii. p. 179, 4to), a Nutmeg Pigeon of the same species as that which occurred at the Friendly Islands.'

The caruncle shown in the cut is dissipated after the breeding season, leaving nothing but a slight cutaneous wrinkle. M. Lesson says that the bird feeds on a berry which is very abundant in the small Isle of Oualan, and that it is not disturbed by the natives.

[Carpophaga oceanica.]

M. Selby gives as a form apparently belonging to this division of the *Columbidæ*, the following species: *Columba Phasianella* (Temm.), the structure of the bill being, as he observes, intermediate between that of *Vinago* and *Columba*, and the feet formed upon the same plan as those of the rest of the *Ptilinopinæ*.

Description.—Length from fourteen to sixteen inches, the tail being seven, and rather more. Wings short, reaching, when closed, about an inch and a half beyond the root of the tail, rounded, and with the third quill longest; the first and fourth being equal to each other. Bill, measuring from the forehead nearly three quarters of an inch long; the tip of the upper mandible moderately arched, and with a notch; that of the lower angulated and strong. Throat, yellowish white. Head, sides, and front of the neck, and whole of the under plumage, orange-brown. Hinder part of neck changeable rich violet-purple, with brilliant gold reflections. Back, wing-coverts, and the rest of the upper plumage, deep reddish-brown, shot with bronze in some lights. Tail graduated or cuneiform, the two middle feathers brown, the lateral marked obliquely with a black bar. Feet and naked part of legs reddish brown. Sole of the hind and inner toes much expanded.

Young differing from the adult in having the neck dirty reddish brown, with narrow bars of black; belly of a pale reddish-grey, minutely and darkly speckled; back inclining to hair-brown; and smaller wing-coverts deeply edged with orange-brown.

M. Temminck first described the species in the 'Linnean Transactions,' from an Australian specimen. It has since been observed in most of the Philippine and Molucca Islands, Java, &c.

Columba Phasianella is an inhabitant of the woods. Its food is said to consist of a kind of pimento and of other aromatic berries, swallowed entire. The flesh is dark, but its flavour is stated to be excellent.

Mr. Selby makes the group to contain *Columba Macroura*, Auct., *Col. nuchalis*, Wagler, and *Col. Reinwardtii*, Temm. 'Of its precise situation,' says Mr. Selby, 'in the circle of the *Columbidæ*, we speak with some degree of

[Columba Phasianella.]

doubt, not having had an opportunity of instituting so strict an analysis of the species as the subject requires; but we believe it will be found to enter among the *Ptilinopinæ* or arboreal pigeons, as the feet and tarsi of its members are similar in form to those of that division, the latter being very short and partly plumed below the joint, the former with the exterior toe longer than the inner, and the hinder toe fully developed; the sole of the foot, by the extension of the membrane, is broad and expansive, and the claws are arched and strong, all of which are characters evidently showing these members to be expressly adapted for perching and prehension, and not for gressorial movements. The bill also in one species (*Col. Reinwardtii*) approaches in point of strength near to that of *Vinago*, and in all of them the tip of both mandibles is hard and firm, the upper one with a visible emargination and moderately arched. Their habits and mode of life are also nearly allied to the other arboreal species, being the constant inhabitants of the woods, and subsisting upon the fruits and berries of various trees and shrubs. M. Temminck, in his description of this species, says that it possesses a structure and form precisely similar to that of the *Columba migratoria* of North America. To this we cannot subscribe, seeing that its essential characters, as above described, are different, and that the only point of resemblance consists in the length of the tail. Indeed, so far removed do we think it from the American group, that we cannot consider it as its analogue in the Asiatic regions where it resides.'

Columba. Auct.

Most ornithologists are agreed that the sub-family *Columbinæ* contains the type of the form of the *Columbidæ*, and that we are to look among the species of our own country for that type. The ring pigeon, Cushat or Queest (*Columba Palumbus*), the wood pigeon (*Columba Œnas*), and the rock pigeon or biset (*Columba livia*), are considered to be the forms in which the peculiarity of structure and habits of the family are most perfectly developed, and of these *Columba Palumbus* is generally taken as the typical point of comparison. The Columbinæ are distinguished by a bill of moderate strength, with a hard tip, bulging and somewhat arched. The nostrils are partly clothed by a soft membrane, and the orbits of the eyes are more or less denuded of feathers. The feet may be called both gressorial and insessorial; for they are so organized, that the action of walking or perching may be performed at pleasure, for the back toe is moderately long, and the claws are so formed and placed as not to interfere with terrestrial progression, while they are at the same time calculated for arboreal prehension. In the types the exterior and interior toes are of equal length. The wings are fully developed and somewhat pointed; the second and third quills are the longest. The tail is generally square, and moderately long.

'In those species,' says Mr. Selby in the work above quoted, 'which are the media of connexion with other groups, the above characters become partially modified, as we see exemplified in the species nearest allied to the *Ptilinopinæ*, or arboreal pigeons, their feet losing the true character of that of the common pigeon, and assuming more of the grasping form than that fitted for progress upon the ground.'

The species are very numerous, and spread over every quarter of the globe.

'The prevailing colour of the pigeons is bluish-gray, of various intensities and shades, frequently embellished upon the neck with feathers having a metallic lustre and peculiar form, and which exhibit various tints of colour according to the light in which they are viewed. They are naturally birds of a wild and timid disposition (though one species has been partly reclaimed), and usually live congregated in extensive flocks, except during the season of reproduction, when they pair. Most of the species seek their food upon the ground. This consists of the different cerealia, as also acorns, beech-mast, and other seeds, and occasionally of the green and tender leaves of particular plants. Their flesh is sapid and nutritious, being of a warm and invigorating nature. Their flight is powerful, very rapid, and can be long sustained, and many species are in the habit of making distant periodical migrations. They are widely disseminated, species of the genus being found in every quarter of the globe, and in all climates, except the frozen regions of the two hemispheres. They build in trees or holes of rocks, making a shallow nest of small twigs loosely put together. Their eggs are never more than two in number, their colour a pure white; they are incubated alternately by both sexes, and are hatched after being sat upon from eighteen to twenty-one days. The young, upon exclusion, are thinly covered with down, which is rapidly succeeded by the proper feathers.' (Selby.) The apparatus for preparing the food for the nestlings has been before adverted to.

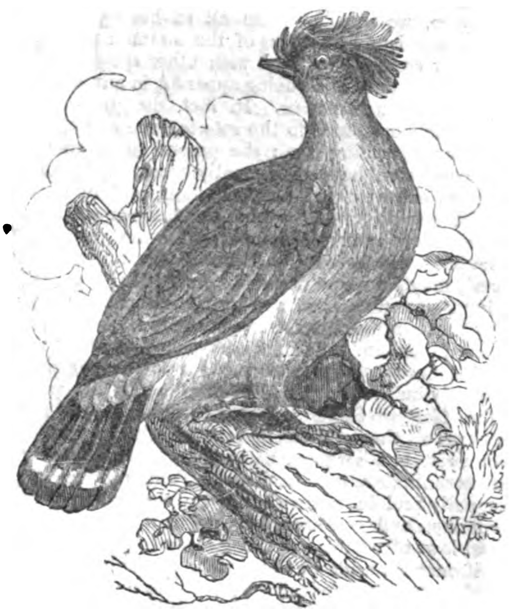
Examples.—Columba spadicea. Mr. Selby places this species as connecting the arboreal species with the typical pigeons, but arranges it under the *Columbinæ* not without doubt, 'for although it presents characters in some of its members approaching those of the pigeons, it cannot be denied that, in its general appearance, and the metallic lustre of its plumage, it also shows evident marks of a near affinity to several species of the genus Carpophaga, and it might perhaps with equal propriety be placed at the extremity of that group;' and regrets the little information extant of its peculiar habits and mode of life, which would have assisted in forming a more satisfactory conclusion as to its proper position. He adds, that from the form and size of the feet we may judge that its habits are more those of an arboreal than terrestrial bird, though its claws want the great curvature of those of the *Ptilinopinæ*, and show its capability of occasionally resorting to the ground for food. M. Lesson, who killed many individuals of this brilliant pigeon, described by Latham and figured by Temminck, says that its flesh is excellent, and that it is very abundant in the woods about the bay of Ipiripi, or the Bay of Islands. The first which he procured was killed and sent to the expedition by one of the officers of the Coquille, and Tou, chief of the hippah of Kaouera, near which she was moored, brought them frequently on board. He adds, that the individual described by Latham as the chestnut-shouldered pigeon came from Norfolk Island, not far from New Zealand, and that M. Temminck indicates the Friendly or Tonga Islands as its native country. This locality, M. Lesson, from whom the following description is taken, seems to doubt.

Total length 16½ inches (French). English authors give it as from 19 to 20; tail 6 inches, nearly rectilineal, and slightly notched; bill rather swollen near the point of the lower mandible, of a brilliant carmine at its base as well as the feet, the tarsi of which are feathered almost to the toes. The eyes are surrounded with a bright-red membrane, and the iris is of the same colour. All the upper parts of the bird, the back, the rump, the wings, and the throat, are of a changeable hue, in which are mingled rosy-copper reflections, running into brilliant and iridescent tints, becoming more sombre upon the great quills. The plumage of the breast, belly, vent, and tarsi, are pure white. The upper part of the tail is brown, slightly tinged with greenish; and below it is brown, which is deepest within and at the extremity.

[Columba spadicea.]

Columba dilopha. 'In this curious species,' says Mr. Selby, 'besides the occipital crest, an ornament which is found in many other birds, there is an additional one in front, composed of long recurved and lax feathers, which not only occupy the forehead, but also the superior part of the soft or basal portion of the bill. This double crest gives the head of the pigeon a character unlike any of its congeners, and more resembling that of some of the crested *Phasianidæ* or *Cracidæ*, with which an analogical relation is thus sustained. In other respects its characters agree with those of *Col. spadicea*, the proportion of the wings and the form of the feet being nearly the same. Temminck, who first described it, observes 'cette nouvelle espèce a le plus de rapports dans toutes ses formes avec la *Columba spadicea*, et toutes les deux sont tres peu différentes de notre Ramier d'Europe.' In the concluding observation we cannot concur to the extent implied by that eminent naturalist; for, although an approach from the fruit-eating pigeons, or Carpophagæ, to the true pigeons, is made by *Col. spadicea* and *dilopha*, still the form of their feet, evidently better adapted for arboreal than terrene habits, and their general aspect, are such as to show that some intermediate form is wanting to bring them into that immediate connexion with the group represented by the European ring pigeon, which M. Temminck seems to intimate.'

Description.—Size nearly that of *Col. spadicea.* Wings long and powerful, reaching when closed beyond the middle of the tail, second, third, and fourth feathers longest, and nearly equal, fifth shorter than the first. Bill rich orange, tip of under mandible obliquely truncated, tip of upper mandible compressed, somewhat arched, culmen rounded. Frontal crest beginning on the upper part of the bill immediately behind the horny tip, and above the nostrils, composed of long curved feathers, soft and loose in texture, and bluish grey tinged with rufous in colour, pointing backwards. Occipital crest rich rufous, bounded on each side from the posterior angle of the eye by a streak of glossy black, decumbent, composed also of long soft feathers with open barbules, each feather widening towards the tip. Side and front of neck and breast pale-grey, black at the base of the feathers, which is hid. The feathers here are trifid at the end: on the back of the neck they are acuminated, but not distinctly divided as upon the breast. Back, scapulars, and wing-coverts deep bluish-grey, the feathers darker at the margin; quills and secondaries bluish-black; under plumage grey. Tail square, basal part and narrow band pale-grey tinged with reddish, tip and broad intermediate bar black; length seven inches. Naked parts of tarsi and toes crimson-red; hind toe strong, with a broad flat sole, and exceeding the tarsus in length; nails long and somewhat curved. *Locality*, New Holland and Java.



[Columba dilopha.]

Passing the *Columba Palumbus* (*Ramier* of the French, *Torquato*, *Ghiandaria*, &c., of the Italians, according to Belon; *Colombaccio*, *Palombo*, *Piccione da Ghianda* of the same, according to Prince Bonaparte; *Ringdufwa* of the Fauna Suecica, *Wildtaube*, and *Ringel-Taube* of the Germans, *Ring-dove*, *Queest*, and *Cushat* of the British, *Ysguthan* of the antient British, and, in Belon's opinion, the Φάττα of the Greeks), and the *Columba Œnas*, (*Palombella*, *Palombella di macchia*, *Piccione topacchio* of the Italians, *Le Pigeon Sauvage* of Brisson, *Stock-Dove* and *Wood-Pigeon* of the British) we come to the *Columba livia;* but, before we enter upon the history of the last-named species, we must observe that the *Cushat* most probably sat for the pretty picture of Virgil's 'aëriæ palumbes,' and that it is considered the type of the Columbinæ. Instances have been known of its laying in aviaries, and Mr. Selby states that he has been informed 'that a pair of ring pigeons, in one of the aviaries of the Zoological Gardens, this last year built their nest in a tree or shrub contained within it, and that the female laid two eggs, which unfortunately were destroyed by some accident during incubation. This fact shows that, under favourable circumstances, and when the habits of the bird are attended to, a progeny may be obtained.' Of *Columba Œnas* Mr. Selby observes, 'Near as it approaches the common pigeon in size and form, no mixed breed that we are aware of has ever been obtained between them, although repeated attempts to effect an intercourse have been made. This in our mind appears a strong and convincing proof, that all the varieties, generally known by the name of Fancy Pigeons, have originated from one and the same stock, and not from crosses with other species, as some have supposed, the produce of which, even could it be occasionally obtained, we have no doubt would prove to be barren, or what are generally termed mules.'

Columba livia. This, the *Pigeon privé** of Bélon, *Le Pigeon domestique* and *Le Biset* and *Le Rocheraye* of Brisson, *Coulon*, *Colombe*, *Pigeon* of the French, *Palombella*, *Piccione di torre*, *Piccione di rocca* of the Italians, *Feldtaube*, *Haustaube*, *Hohltaube*, *Blau Taube*, and *Holtz Taube* of the Germans, *Wild Rock Pigeon* of the British, *Colommen* of the antient British, is the stock from which ornithologists generally now agree the domestic pigeon and its varieties are derived. 'Under this species,' writes Mr.

---

* Belon is of opinion that this is the Περιστερὰ of the Greeks. He seems to have the domesticated race in view; while his Πελειὰς, Livia Columba, Palumbus minor, Livia, Palumbella, Biset, Croiseau, would seem to be the wild rock-pigeon.

Selby, 'we include not only the common pigeon, or inhabitant of the dove-cot, but all those numerous varieties, or, as they are frequently termed, races of domesticated pigeons, so highly prized, and fostered with such care and attention by the amateur breeder or pigeon fancier; for, however diversified their forms, colour, or peculiarity of habit may be, we consider them all as having originated from a few accidental varieties of the common pigeon, and not from any cross of that bird with other species, no signs or marks whatever of such being apparent in any of the numerous varieties known to us. In fact, the greater part of them owe their existence to the interference and the art of man; for by separating from the parent stock such accidental varieties as have occasionally occurred, by subjecting these to captivity and domestication, and by assorting them and pairing them together, as fancy or caprice suggested, he has at intervals generated all the various races and peculiar varieties which, it is well known, when once produced, may be perpetuated for an indefinite period, by being kept separate from, and unmixed with, others; or what by those interested in such pursuits is usually termed 'breeding in and in.' Such also, we may add, is the opinion of the most eminent naturalists as to their origin, and it is strongly insisted on by M. Temminck in his valuable work, the 'Histoire Générale Naturelle des Pigeons.' Indeed the fact that all the varieties, however much they may differ in colour, size, or other particulars, if permitted, breed freely and indiscriminately with each other, and produce a progeny equally prolific, is another and a convincing proof of their common and self-same origin; for it is one of those universal laws of nature, extending even to plants, and one which, if once set aside or not enforced, would plunge all animated matter into indescribable confusion, that the offspring produced by the intercourse of different, that is, distinct species, is incapable of further increase. That such an intercourse may be effected is well known to all; but it is generally under peculiar or artificial circumstances, and rarely when the animals, birds, or whatever they may be, are in their natural state, and in a condition to make their own election. It is seen in the crosses obtained in a state of confinement between the canary and goldfinch, linnet, &c.; in the hybrids between different species of *Anatidæ*, when domesticated or kept in captivity; in the cross between the pheasant and common fowl, &c.***

'The bastard produce of the common wild turtle (*Turtur communis*) with the turtle of the aviary (*Turtur risorius*) has been proved by frequent experiment to be barren, although the two species from whence it originates appear to be closely allied, and a mixed breed is easily procured; and such, we have no hesitation in saying, would be the event, if a cross could be obtained between the common pigeon and the ring pigeon, the wood pigeon, or any other species.'[*] These observations are well worthy of attention. The assertion respecting the bastard produce of the turtles, made above, is corroborated by MM. Boitard and Corbié in their History of the Pigeons de Voliere, and the principle is further confirmed by the experiments of Mauduyt, Vieillot, and Corbié.

The varieties of this bird, produced under the fostering hand of man, the tumblers, croppers, jacobines, runts, spots, turbits, owls, nuns, &c. &c., would fill a volume. Our limits will not permit us to figure or describe them. The *carrier* however demands notice. In one of his odes (εἰς περιστερὰν) Anacreon has immortalized it as the bearer of epistles. Taurosthenes sent to his expectant father, who resided in Ægina, the glad tidings of his success in the Olympic games on the very day of his victory. Pliny (*Nat. Hist.*, book x., 37,) speaks of the communication kept up between Hirtius and Decimus Brutus at the siege of Mutina (Modena); 'what availed Antony the trench and the watch of the besiegers; what availed the nets (retia) stretched across the river, while the messenger was cleaving the air (per cœlum eunte nuntio).' The crusaders employed them, and Joinville records an instance during the crusade of Saint Louis. Tasso, (Gierusalemme Liberata, cant. xviii.) sings of one that was attacked by a falcon and defended by Godfrey,

> 'Che dal collo ad un filo auinta pende
> Rinchiusa carta, e sotto un' ala ascosa.'

which 'carta' Godfrey of course reads, and is put in possession of all the secrets. In the same way Ariosto (cant. xv.) makes the 'Castellan di Damiata' spread the news of Orrilo's death all over Egypt. Sir John Maundeville, knight, warrior, and pilgrim, who penetrated to the border of China in the reigns of our Second and Third Edward, thus writes: 'In that contree and other contrees beyonde, thei han a custom, whan thei schullo usen werre, and whan men holden sege abouten cytee or castelle, and thei withinnen dur not senden out messagers with lettere, fro lord to lord, for to aske sokour, thei maken here letters and bynden them to the nekke of a *Colver*, and letten the *Colver* flee and the *Colveren* ben so taughte, that thei fleen with the letters to the very place, that men wolde sende hem to. For the *Colveres* ben norysscht in tho places, where thei ben sent to; and thei senden hem thus for to beren here letters. And the *Colveres* retournen azen, where as thei ben norisscht and so they don comounly.'

The carrier however gradually sank, in this country at least, to the bearer of the intelligence of the felon's death at Tyburn—Hogarth's print will occur to every body: it became the messenger from the race-course and prize-ring, and is now said to be largely used in stock-jobbing transactions. Every day we read remonstrances on this subject, and accounts of some of the hapless messengers being shot; nay, the fostering of a breed of falcons has been threatened, to oppose their progress to our shores. Some idea of the astonishing fecundity of the domesticated pigeon may be derived from the assertion of Biberg, who observes that if you suppose two pigeons to hatch nine times a year, they may produce in four years 14,760 young.[*]

In its wild state the rock pigeon is widely distributed; the rocky islands of Africa and Asia, and in the Mediterranean, abound with them. Virgil's beautiful simile in the Fifth Æneid evidently relates to this species:—

> 'Cui domus et dulces latebroso in pumice nidi.'

In the Orkneys and Hebrides it is said to swarm. 'It is also met with upon the northern and western coasts of Sutherland, the perforated and cavernous rocks which gird the eastern side of Loch Eriboll, and those of the limestone district of Durness, furnishing suitable places of retreat; and again upon the eastern coasts of Scotland it is seen about the rocky steeps of the Isle of Bass and the bold promontory of St. Abb's Head.' (Selby.)[†]

Description of *Columba livia* in its wild state:—Bill blackish brown; the nostril membrane red, sprinkled, as it were, with a white powder. The irides pale reddish orange. Head and throat bluish grey. Sides of the neck and upper part of the breast dark lavender purple, glossed with shades of green and purplish red. Lower part of

[Columba livia.]

---

[*] Naturalist's Library, Ornithology, vol. v., p. 152. A work, of which the letter-press and figures improve with every volume.

[*] Biberg says 14,672; but Stillingfleet (*Tracts*, p. 90, 3d ed.) says that the numbers ought to be as above, or the expression should be altered, as Biberg includes the first pair.

[†] We are informed that at Somerset House, London, pigeons have made their nests about the building, both on the side towards the water and inland, for the last sixty years. The birds that so make their nests are said to be the blue ones. Were these originally wild birds, or have they returned to something like their wild habits from the domesticated state? Most probably they had been domesticated.

breast and abdomen bluish grey. Upper mandible and wing-coverts blue grey. Greater coverts and secondaries barred with black, so that there are two broad and distinct bars across the closed wings. Lower part of the back white; rump and tail-coverts blueish grey. Tail deep grey, with a broad black bar at the end. Legs and feet pale purplish red. Wings when closed reaching within half an inch of the end of the tail. (Selby).

Ectopistinæ (Selby).

Turtur.

Bill more slender than that of the pigeons. Tip of the upper mandible gently deflected, that of the lower scarcely exhibiting the appearance of an angle. Tarsi rather shorter than the middle toe. Feet formed for walking or perching; inner toe longer than the outer. Front of tarsi covered with broad imbricated scales. Wings, first quill a little shorter than the second, third longest of all. Tail rounded or slightly graduated. (Selby).

Example.—Turtur risorius, Columba risoria, Auct; *Turtur torquatus Senegalensis,* Brisson; *Tourterelle à collier,* Buffon; probably the turtle of the Scriptures, and still plentiful in Egypt and other eastern countries, where it is often kept in confinement. The relics of Greek and Roman art give a very fair representation of this species; but Belon and others seem to be of opinion that the *Turtur communis,* common turtle-dove, was the *τρύγων* of the Greeks.

Description of a wild specimen from Southern Africa. Length about ten inches. Chin whitish; from the corners of the mouth to the eyes a narrow streak of black. Forehead pale bluish-grey; crown darker; cheeks, neck, breast, and belly grey, tinged with vinaceous or pale purplish-red; the hind neck with a demi-collar of black; some of the side feathers of the collar tipped with white. Back, scapulars, and rump, pale clove brown, with a greenish tinge. Margins of wings, greater coverts, and under wing-coverts blue grey. Greater quills hair brown, delicately edged with greyish-white. Vent and under tail-coverts white. Legs and feet grey; inner toe a little longer than the outer. (Selby).

Habits and Food.—In its natural state it haunts the woods, where it breeds, making a nest like that of the common turtle, and lays two white eggs. It seeks its food in the open grounds, and subsists upon grain, grass seeds, and pulse, &c. Its trivial name is derived from a fanciful resemblance to the human laugh in its cooings. (Selby).

[Turtur risorius.]

Hybrids.

A race between the common turtle and this species has been obtained; but the mules are stated to have been invariably barren.

Mr. Selby provisionally places the *Columba lophotes* of Temminck under this genus.

Ectopistes (Swainson).

Bill slender, notched. Wings rather elongated, pointed; the first and third quill equal; the second longest. Tail rounded, or curvated. Feet short, naked; anterior scales of the tarsi imbricate; lateral scales very small, reticulate. Types:—*Col. speciosa,* Temm.; *Col. migratoria,* Linn. (Swainson).

Example.—Ectopistes migratoria, Columba migratoria, Auct. The *Passenger Pigeon,* Wilson, Audubon, and others. Our limits not allowing us to give a detailed history of any length of the habits of more than one species, we have selected Wilson's graphic account of this elegant bird as the most striking.

'The roosting-places are always in the woods, and sometimes occupy a large extent of forest. When they have frequented one of those places for some time, the appearance it exhibits is surprising. The ground is covered to the depth of several inches with their dung; all the tender grass and underwood destroyed; the surface strewed with large limbs of trees, broken down by the weight of the birds collecting one above another; and the trees themselves, for thousands of acres, killed as completely as if girdled with an axe. The marks of their desolation remain for many years on the spot; and numerous places could be pointed out where, for several years after, scarcely a single vegetable made its appearance. When these roosts are first discovered, the inhabitants, from considerable distances, visit them in the night with guns, clubs, long poles, pots of sulphur, and various other engines of destruction. In a few hours they fill many sacks, and load horses with them. By the Indians, a pigeon-roost or breeding-place is considered an important source of national profit and dependence for that season, and all their active ingenuity is exercised on the occasion. The breeding-place differs from the former in its greater extent. In the western countries, viz., the states of Ohio, Kentucky, and Indiana, these are generally in back woods, and often extend in nearly a straight line across the country for a great way. Not far from Shelbyville, in the state of Kentucky, about five years ago, there was one of these breeding-places, which stretched through the woods in nearly a north and south direction, was several miles in breadth, and was said to be upwards of forty miles in extent. In this tract almost every tree was furnished with nests wherever the branches could accommodate them. The pigeons made their first appearance there about the 10th of April, and left it altogether with their young before the 25th of May. As soon as the young were fully grown, and before they left the nests, numerous parties of the inhabitants, from all parts of the adjacent country, came with waggons, axes, beds, cooking utensils, many of them accompanied by the greater part of their families, and encamped for several days at this immense nursery. Several of them informed me that the noise was so great as to terrify their horses, and that it was difficult for one person to hear another speak without bawling in his ear. The ground was strewed with broken limbs of trees, eggs, and young squab pigeons, which had been precipitated from above, and on which herds of hogs were fattening. Hawks, buzzards, and eagles were sailing about in great numbers, and seizing the squabs from the nests at pleasure, while, from twenty feet upwards to the top of the trees, the view through the woods presented a perpetual tumult of crowding and fluttering multitudes of pigeons, their wings roaring like thunder, mingled with the frequent crash of falling timber; for now the axemen were at work, cutting down those trees that seemed to be most crowded with nests, and contrived to fell them in such a manner, that in their descent they might bring down several others; by which means, the falling of one large tree sometimes produced 200 squabs, little inferior in size to the old ones, and almost one heap of fat. On some single trees, upwards of 100 nests were found, each containing one squab only; a circumstance in the history of this bird not generally known to naturalists. It was dangerous to walk under these flying and fluttering millions, from the frequent fall of large branches, broken down by the weight of the multitudes above, and which, in their descent, often destroyed numbers of the birds themselves; while the clothes of those engaged in traversing the woods were completely covered with the excrements of the pigeons.

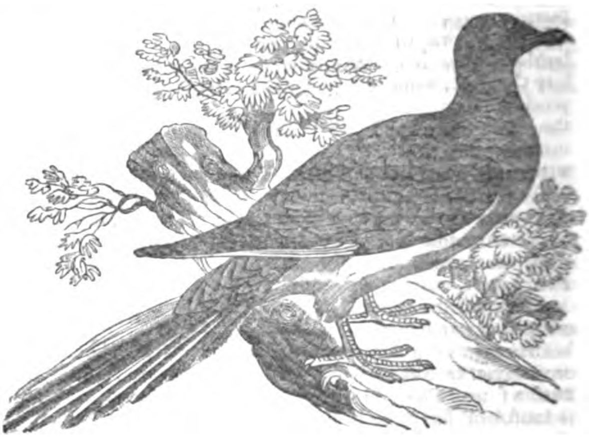
'These circumstances were related to me by many of the most respectable part of the community in that quarter, and were confirmed in part by what I myself witnessed. I passed for several miles through this same breeding-place, where every tree was spotted with nests, the remains of those above described. In many instances I counted upwards of ninety nests on a single tree; but the pigeons had abandoned this place for another, sixty or eighty miles off, towards Green River, where they were said at that time to be equally numerous. From the great numbers that were constantly passing over our heads to or from that quarter, I had no doubt of the truth of this statement. The mast had been chiefly consumed in Kentucky; and the pigeons, every morning a little before sunrise, set out for the Indiana territory, the nearest part of which was about sixty miles distant. Many of these returned before ten o'clock, and the great body generally appeared on their return a little after noon. I had left the public road to visit the remains of the breeding-place near Shelbyville, and was traversing the woods with my gun, on my way to Frankfort, when, about ten o'clock, the pigeons which I had observed flying the greater part of the morning northerly, began to return in such immense numbers as I never before had witnessed. Coming to an opening by the side of a creek called the Benson, where I had a more uninterrupted view, I was astonished at their appearance: they were flying with great steadiness and rapidity, at a height beyond gun-shot, in several strata deep, and so close together that, could shot have reached them, one discharge could not have failed of bringing down several individuals. From right to left, as far as the eye could reach, the breadth of this vast procession extended, seeming every where equally crowded. Curious to determine how long this appearance would continue, I took out my watch to note the time, and sat down to observe them. It was then half-past one; I sat for more than an hour, but instead of a diminution of this prodigious procession, it seemed rather to increase, both in numbers and rapidity; and, anxious to reach Frankfort before night, I rose and went on. About four o'clock in the afternoon, I crossed Kentucky river, at the town of Frankfort, at which time the living torrent above my head seemed as numerous and as extensive as ever. Long after this I observed them in large bodies that continued to pass for six or eight minutes, and these again were followed by other detached bodies, all moving in the same south-east direction, till after six o'clock in the evening. The great breadth of front which this mighty multitude preserved would seem to intimate a corresponding breadth of their breeding-place, which, by several gentlemen who had lately passed through part of it, was stated to me at several miles.'

Wilson then enters into a rough calculation of the numbers of this mass, and he comes to the conclusion that its whole length was 240 miles, and that the numbers composing it amounted to 2,230,272,000 pigeons, observing that this is probably far below the actual amount. He adds, that allowing each pigeon to consume half a pint of food daily, the whole quantity would equal 17,424,000 bushels daily. Mr. Audubon confirms Wilson in every point, excepting that he very properly corrects that part of the narrative which would lead to the conclusion that a single young one only is hatched each time. The latter observes that the bird lays *two* eggs of a pure white, and that each brood generally consists of a male and female.

Description.—Wings long and acuminate, having the second quill feather exceeding the others in length. The tail is greatly cuneiform or graduated, and consists of twelve tapering feathers. Bill black, and like that of the turtle. Legs purplish-red, short, and strong. Iris bright orange-red, the naked orbit purplish-red. Head and cheeks pale bluish-grey. Fore-neck, breast, and sides brownish-red, with a purplish tinge. Abdomen and vent white. Lower part and sides of neck purplish-crimson, reflecting tints of emerald green and gold. Upper plumage deep bluish-grey, some of the scapulars and wing-coverts spotted with black. Greater coverts grey, tipped with white. Quills blackish-grey, their exterior webs bluish-grey. Tail with the two middle feathers black, the other five on each side grey at the base, with a black bar on the interior arch, and passing into white towards the extremities.

The female is rather smaller, and has the colours of her plumage much duller than those of the male, though the distribution is the same. (Selby.) *Locality*, North American Continent, between the twentieth and sixty-second degrees of north latitude. Mr. Eyton has figured one as a visitant to our shores, on the authority of Dr. Fleming, who, in his 'History of British Animals,' says that one was shot in the parish of Monymeal, Fifeshire, on the 31st December, 1825.

Mr. Selby refers provisionally *Columba Capensis*, Auct., *Columba Macquarrii*, Lesson, and *Columba venusta*, Temm. to his group of *Ectopistinæ*, and thinks that by these and some other nearly allied forms, a passage to the next group, *Peristerinæ*, the ground doves, is effected.



[Ectopistes migratoria.]

Peristerinæ (Selby).

Distinguished from the preceding groups by their terrene habits, and their evident approach in many points to the more typical Rasores or Gallinaceous birds. In these the bill is rather slender, frequently subemarginate, and the tip of the upper mandible but gently deflected; the wings are generally short and rounded, and in many instances concave, as in the partridge, grouse, &c. The legs are considerably longer than in the typical pigeons; the tarsus usually exceeding the middle toe in length, and the feet better adapted for walking than grasping; the claws are obtuse and slightly arched. The hallux is shorter, and its relative position different from that of the arboreal species. Their plumage is plainer and more uniform in tint than that of some of the preceding groups, though it is still brilliant in those species which connect them with other forms. They live almost entirely upon the ground, and many of the species run with great celerity, on which account they have been called partridge pigeons. Their flight, which is usually low, is effected with greater exertion than that of the pigeons, and is never long sustained. (Selby.)

Mr. Selby observes that this division contains a great number of species, and is of opinion that when better investigated, it will be found divisible into a variety of minor groups or genera. He places under it Phaps, Chamæpelia, and Peristera. This group is distinguished by a longer bill, very faintly emarginate, and by its tarsi, which are moderately long and naked, with the frontal scales divided into two series, and the sides and hinder part reticulated with minute scales. Another group, he adds, seems indicated by certain Asiatic species, conspicuous for the rich metallic green of the plumage of their backs, resembling therein some of the *Ptilinopinæ*. The tarsi of these are destitute of scales, except a few indistinct ones in front, just above the toes. The bill is rather long, and destitute of a notch. They live mostly on the ground, but their flight is powerful. Mr. Selby takes *Columba superciliosa* of Wagler as the type of this last-mentioned group.

Phaps (Selby).

Bill moderately long, rather slender; upper mandible gently deflected at the tip, and with the indication of a notch or emargination. Wings of mean length; second and third feathers longest, and nearly equal. Tail slightly rounded. Legs, tarsi as long as the middle toe, the front covered with a double row of scales, sides and back reticulated with small hexagonal scales. Hind toe short; inner toe exceeding the outer in length. Claws blunt, slightly arched. Type, *Columba chalcoptera*, Latham; *Columba elegans*, Temm.; and *Columba picata*, Wagler, belong to this group. (Selby.)

Example.—*Phaps chalcoptera*, *Columba chalcoptera*, Latham; *Columba Lumachelle*, Temm.; bronze-winged ground dove.

Size about that of *Columba Œnas*. Total length, about fifteen inches. Bill, from edges of the gape, hardly an inch; black anteriorly; reddish near the base. Forehead, stripe below the eyes, and throat white; crown brown, tinged with reddish, filleted with dusky red; cheeks and sides of neck bluish-grey; bottom of neck in front and breast purplish-grey. Belly and vent grey, with a pale purple tinge. Back, scapulars, rump, and upper tail-coverts brown tinged with greenish in some lights, the border of each feather paler. Wing-covers bluish-grey, but the outer webs of every feather have a large ovate spot, producing various tints of metallic brilliancy according to the direction of the light. Quills brown above, with the inner surface of the webs, the axillary feathers, and under wing-coverts bordered rather deeply with pale orange-red. Tail slightly rounded, bluish-grey, with a black band. Legs red; two rows of scales in front, the sides reticulated.

Locality and Habits.—Australia and islands in the Pacific. In the neighbourhood of Sydney, from September till February.

Haunts dry and sandy places, where it is generally seen on the ground, and occasionally perched upon the low branches of shrubs. *Nest* inartificial, in holes of low trees or decayed trunks near the ground; sometimes on it. *Eggs* two, white. These birds go in pairs generally: their cooing is loud, and has been compared, when heard at a distance, to the lowing of a cow.

[Phaps chalcoptera.]

Chamæpelia* (Swainson)

Bill slender, entire. Wings rounded, the first quill short; third, fourth, and fifth nearly equal and longest, the webs on both sides slightly emarginate. Tail rounded. Feet rather short, the sides of the tarsi feathered. Types, *Columbæ passerina*, Linn.; *squamosa*, Temm. (Swainson).

Example.—Chamæpelia Talpicoti, Columba Talpicoti, Temm., the species which Mr. Selby considers to be the type. Length six inches and a quarter, adult male; forehead, crown, and nape of neck ash-grey; cheeks and throat pinkish-white; upper plumage entirely brownish-orange, with the exception of a few transverse streaks of black upon the exterior webs of some of the wing-coverts nearest the body; under plumage deep vinaceous red; axillary feathers and part of under wing-coverts black; tail with the two middle feathers brownish-orange, the remainder brownish-black, with reddish-brown tips, moderately curved; bill and orbits bluish-grey; legs and toes pale-red, the outer side of the tarsus with a row of small feathers down the line of junction between the acrotarsia and paratarsia; quills broad, the fourth with a large projecting notch towards the middle of the inner web. The female has the crown of the head of a sordid grey; the upper plumage of a wood-brown, tinged with red; the scapular and wing-coverts marked as on the male; under plumage dirty-grey, tinged with pale purplish-red. (Selby.)

Locality and Habits.—Brazil, Paraguay, and other districts of South America. Haunts open grounds near woods, where it roosts and breeds upon the underwood, but never far from the ground, where it is active, and feeds upon the smaller cerealia, berries, &c. Generally observed in pairs, sometimes in families of four or six, never in large flocks. Does not fly from the face of man, but affects the confines of houses and farm-yards. Easily kept and propagated in aviaries.

[Chamæpelia Talpicoti.]

Peristera (Swainson).

Bill slender, sub-emarginate. Wings rounded, the first quill short and abruptly attenuated, second and fifth equal, third and fourth equal and longest. Tail rounded. Feet strong, naked, somewhat lengthened; anterior scales of the tarsi imbricate, lateral scales none. Type, *Columba cinerea*, Temm. (Swainson).

Example.—Peristera tympanistria, Columba tympanistria, Temm. Length about nine inches; upper plumage brown, slightly tinged with grey on the neck; large spots of shining dark-green on the outer webs of three or four of the greater wing-coverts; middle tail-feathers brown; the two exterior on each side grey, with a broad black bar near the tip; inner webs of greater quills deep brown; forehead, streak over the eye, and under plumage pure white; under wing-coverts and sides pale orange-brown; under tail-coverts brown; bill and legs grey, the latter with a reddish tinge.

Locality.—South Africa, where it is said to haunt woods. The species does not seem to be common.

[Peristera tympanistria.]

Geophilus (Selby).

Mr. Selby, speaking of *Columba cyanocephala*, Wagler, *Turtur Jamaicensis*, Brisson; *Columba carunculata*, Wagler; and *Columba Nicobarica*, Latham, *Columba Gallus*, Wägler, says, 'Whether they will form a separate division, or the three first will enter among the Peristerinæ, and the Lophyrus alone remain a representative of another group, we are unable to determine, not possessing sufficient materials to institute so strict an analysis as is necessary, or to trace out with precision the direct affinities of those species, and the situation they hold in respect to the other groups of the *Columbidæ*, as well as those of the adjoining families. The three first we have provisionally included in the genus *Geophilus*. In their form and habits they approach still nearer to the typical Gallinaceous birds than the species we have just been describing. Their tarsi are long, and covered with hexagonal scales; their tail short, and rather pendent; their wings concave, short, and rounded; and their body, as compared with the typical pigeons, thick and heavy. A striking departure from the general economy of the Columbidæ is further observed in their mode of propagation, the number of the eggs they lay each hatching not being confined to two, as is seen to prevail in the groups already described, but extending to eight or ten, which are incubated upon the ground, and the young, like those of the true Gallinaceous birds, are produced from the egg in such a state as to be able immediately to follow the parent, which broods over and attends them like the partridge or domestic fowl. They live entirely upon the ground, except during the hours of repose, when they sometimes retire to bushes, or the low branches of trees. They walk and run with great quickness, like the *Gallinæ*, and in fact appear to be the forms which immediately connect this family with the Pavonidæ and Tetraonidæ. Although for the present we have placed the first three under the same generic head, yet from their distinct geographical distribution, and the difference observed in the bill of the first, it is more than probable that a further division will be required.'

---

* Printed generally Chæmepelia. The derivation we take to be χαμαὶ and πέλεια, 'ground-dove.'

Geophilus carunculatus, *Columba carunculata*, Temm.; *Colombe Galline*, Le Vaill. Size about that of the Common Turtle, but with the body stouter and more rounded. Base of the bill and forehead covered with a naked red wattle; another wattle of the same hue depends from the chin, and branches of it extend upwards towards the ears. Plumage of head, cheeks, neck, and breast purplish-grey; back, scapulars, and wing-coverts pale grey; feathers bordered with white. Belly, upper and under tail-coverts, flanks, and under wing-coverts white. Tail short, rounded, deep ruddy-brown, except the outer feather on each side: these have the outer web white. Legs covered with hexagonal scales, purplish-red. Iris with a double circle, yellow and red. The female has no wattle, and her colours are less pure. (Le Vaillant.)

[Geophilus carunculatus.]

Locality and Habits.—South Africa, where it was discovered in the Great Namaqua country by Le Vaillant, who gives the following account of its habits and affinities:—'To the pigeons its affinity is shown by the form of the bill and the plumage; while it differs from them in the pendent wattle, elongated tarsi, rounder body, less graceful form, tail, which it carries hanging down like that of a partridge, and rounded wings, points which bring it near to the *Gallinæ*.' A passage is thus formed by it, in his opinion, between those birds and the pigeons. The nest, composed of twigs and the dried stems of grasses, is formed in some slight hollow of the ground, and there the female lays six or eight reddish-white eggs, which are incubated by both the parents. The young are hatched clothed with down of a reddish-grey, run immediately and follow their parents, which keep them together by a peculiar oft-repeated cry, and brood over them with their wings. Their first food consists of the larvæ of ants, dead insects, and worms, which the parents point out to them. When strong enough to find their own food, they live on grain of different sorts, berries, insects, &c., and keep together in coveys like the partridge and other Tetraonidæ till the pairing-time.

If the wattles of the last-named species recall to the observer the same parts so highly developed in the Gallinaceous birds, the species which we next present will remind him of the hackles which ornament the Gallinæ.

Geophilus ? Nicobaricus, *Columba Nicobarica*, Latham; *Columba Gallus*, Wägler. Length hardly fifteen inches: bill slender, about 1¼ inch long, tip but little bent downwards; the tail pure white, the quills deep blackish-blue, with varying tints of green; all the rest of the plumage rich metallic green, shooting, according to the light, into the variegated tints of golden green, bronze, bright copper colour, and deep purplish-red; neck-feathers long, narrow, and pointed, like those of the domestic cock; barbules towards the tip silky and distinct; tail short, pendent, nearly square; wings, when closed, reaching nearly to the termination of tail; legs strong, moderately long, black, covered with hexagonal scales; nails yellow, gently curved, blunt. Upon the base of the upper mandible of the male a round fleshy tubercle (probably apparent in the breeding season only). The female resembles the male in colour, but her neck-feathers are not so long, and she has no tubercle.

[Geophilus Nicobaricus.]

Locality and Habits.—The isles of Nicobar, Java, Sumatra, and many of the Moluccas. Authors differ about its habits, some asserting that its nest is placed on the ground, and that the female lays several eggs, the young running as soon as hatched; but Mr. Bennet, who saw them in Mr. Beale's aviary at Macao, says that they were usually seen perched upon the trees, even upon the loftiest branches, and adds, that they build their rude nests and rear their young upon trees, similar to all the pigeon tribe.

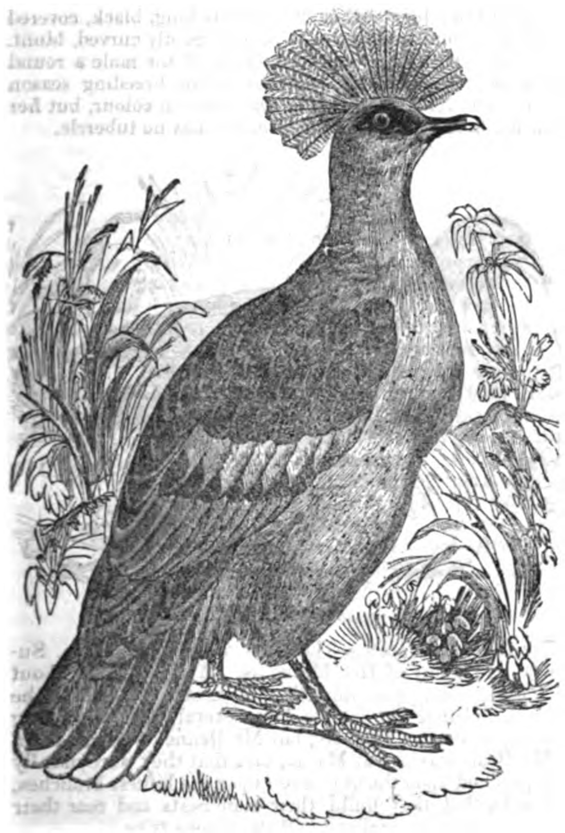
Lophyrus (Vieillot).

Bill moderate, rather slender, and slightly gibbous towards the tip; upper mandible channelled (*sillonnée*) on the sides, inclined towards the point; nostrils situated in a groove; wings rounded (Vieillot).

Example.—*Lophyrus coronatus*, *Columba coronata*, Latham; *Phasianus cristatus Indicus*, Brisson; *Colombe Hocco*, Le Vaill.; *Colombe Galline Goura*, Temm.; *Great Crowned Pigeon*, Edw. A species surpassing in size all the other *Columbidæ*. Total length from twenty-seven to twenty-eight inches; bill two inches long, black, tips of mandibles thickened, that of the upper one somewhat deflected; head with a large, elevated, semicircular, compressed crest of narrow straight feathers, with decomposed or rather disunited silky barbules always erect; crest and body below greyish-blue; feathers of back, scapulars, and smaller wing coverts, black at the base, rich purple-brown at the tips; greater coverts same colour, but centrally barred with white, forming a single transverse band across the wings when closed; quills and tail deep grey, the latter terminated with greyish-blue; legs grey; tarsi 3½ inches in length, covered with rounded scales not closely set, with a white border of skin round each; toes strong and somewhat short, scales placed as in the *Columbinæ*.

Locality and Habits.—Many of the islands of the great Indian group. Not rare in Java and Banda, abundant in New Guinea, and in most of the Moluccas. Nest built in trees; eggs two; cooing of the male hoarse, accompanied by a noise somewhat like that of a turkey cock when strutting; food—berries, seeds, grain, &c.; flavour of the flesh said to be excellent.

'In this magnificent and beautiful bird,' says Mr. Selby, 'we observe a combination of form different from that of the ground pigeons, so lately described; for, instead of the marked affinity to the typical rasorial families, the *Pavonidæ* and *Tetraonidæ*, so decidedly exhibited by these species, both in their mode of life, and in their deviation from the usual Columbine figure, we have, in the present instance, an approximation of structure much nearer that of some of the *Cracidæ*, another tribe of birds which constitutes an aberrant family of the Rasorial Order, and it is on this account we think that this bird cannot well be placed in the same division with the ground doves, but must constitute the type of a separate group.'



[Lophyrus coronatus.]

FOSSIL COLUMBIDÆ.

Dr. Buckland enumerates the bones of the pigeon among the remains in the cave at Kirkdale, and figures a bone which he says approaches closely to the Spanish runt, which is one of the largest of the pigeon tribe, meaning, we suppose, the *Columbidæ*.

COLUMBINE. [AQUILEGIA.]

COLUMBIUM, a metal discovered, in 1801, by Mr. Hatchett in a ferruginous mineral from North America. It was afterwards detected in some Swedish minerals by Ekeberg, who supposed it to be a different and new metal, to which he gave the name of *Tantalum*. Dr. Wollaston showed that the metals were the same. The minerals found in Sweden are *tantalite* and *yttro-tantalite*. The first, sometimes called also *Columbite*, occurs amorphous and nodular, and also crystallised in the form of a right rhombic prism. The massive variety is either granular or compact; the crystals are greyish-black: fracture uneven. hardness, 6: specific gravity, 6·038: lustre, imperfect metallic: it is opake. It contains about 80 per cent. of oxide of columbium, 12 of oxide of iron, and 8 of oxide of manganese. The yttro-tantalite contains oxide of columbium, yttria, and some other substances.

Columbium is obtained with great difficulty. Berzelius procured it by heating potassium with the potasso-fluoride of columbium. It is a black powder, which by the burnisher acquires the colour and lustre of iron. The specific gravity is about 6. It is nearly insoluble in acids and in chlorine. When heated in the air it is oxidized, and converted into columbic acid.

Oxygen and *Columbium* combine in two proportions, forming columbic acid and oxide of columbium.

Columbic acid may be obtained by burning the metal in the air; it is colourless, insipid, and does not act upon vegetable blue colours. When heated with charcoal it is reduced to the state of oxide. If heated with iron it loses oxygen, and an alloy of iron and columbium is formed. Columbic acid combined with water forms a very white hydrate, which reddens vegetable blues. It combines with salifiable bases to form salts which are called *columbates*, but no one of them is of any importance, or applied to any purpose whatever.

Columbic acid is composed of

3 equivalents of oxygen . .	24
1 equivalent of columbium .	185
Equivalent . .	209

Oxide of Columbium is obtained by heating columbic acid to whiteness in a covered crucible. It is of a greyish black colour, very hard, and almost infusible.

Oxide of columbium consists of

2 equivalents of oxygen . .	16
1 equivalent of columbium .	185
Equivalent . .	201

Columbium combines also with chlorine and sulphur, &c., but these compounds are little known and of no importance.

COLUMBO, or COLOMBO, the capital and seat of the British government in Ceylon, is situated on the western coast of the island, 6° 57′ N. lat., and 80° E. long., 368 miles S.W. from Madras. The fort is on a promontory, two-thirds of the extent of which is washed by the sea. It derives strength from art and from nature: it embraces a circuit of about a mile and a quarter, and has eight principal bastions. Four of these bastions are towards the sea, and three face a lake and command the narrow approach from the town. The fort is surrounded, except on the side of the sea, with a deep moat, and a lake bordering on the glacis adds to the strength of the place. On the side of the sea, where the surf does not render a landing impracticable, every part is well commanded by the batteries. Inside the fort are several straight and regular streets. The residence of the governor, called the 'King's house,' is in King's Street; and behind it is the light-house, a beautiful edifice, lately erected, the light of which is ninety-seven feet above the level of the sea. The principal government offices and courts are within the fort; also an English church, a library, a medical museum, an hospital, two hotels, and numerous shops.

The lake before alluded to, being connected by canals with the Mutwal river, almost insulates the town. In the centre of the lake is a piece of land called Slave island, covered with cocoa-nut trees, and easy of access from the town or fort by a small stone bridge. It is the head-quarters of the Ceylon Rifle regiment.

Columbo has a small semicircular harbour admitting vessels not exceeding 200 tons. Ships of larger burden anchor in the roads. In the S.W. monsoon, from April to October, the best anchorage is found in from seven to eight fathoms, light-house bearing S. by E. ½ E., and the Dutch church E. by S. In the N.E. monsoon, from November to April, it is more convenient to anchor in six and a half fathoms, light-house bearing S. or S. ½ E., and the Dutch church E.S.E.

The town is regularly built, with fifteen streets, eight running E. and W. and the others at right angles to them. The houses are built of cabook, white-washed, and presents a good appearance. In 1814 there were 2654 houses within the gravets*. Between 1820 and 1829, 6512*l.* was collected by assessment for lighting and repairing the streets. The amount collected is greater than what is expended, and the surplus money is put out at interest, it being intended to discontinue assessments when the interest of the surplus shall amount to 1200*l.* per annum.

Among the public buildings are the Supreme Court-house, and the various public offices. There is also a library belonging to the burghers, a small-pox hospital, a masonic hall, and a number of religious edifices. The Dutch church, erected in 1746, is a lofty building in the form of a cross, standing in the centre of the town.

There are two steam-engines, and several native presses used in the manufacture of cocoa-nut oil.

The population is composed of Europeans, burghers, Malabars, Singhalese, and Moors, besides some Malays, Chinese, Parsees, Caffrees, and Pattangs; and according to the census of 1832, amounted to 31,519.

The commerce, external and internal, is very extensive, and daily increasing. The exports to Europe are cinnamon, pepper, coffee, cocoa-nut oil, plumbago, cordage, arrack, cardamoms, elephants' tusks, deer horns, tortoise-shells, ebony, satin-wood, &c.; and the imports consist of articles of European manufacture.

The climate of Columbo is very salubrious. The mean daily variation of the temperature is from 76° to 86½° Fahr. The tropical rains are here sometimes accompanied with dreadful thunder storms.

Columbo is mentioned in Singhalese history as early as 495 A.D. About the year 1371 it was frequented by trading vessels, and a colony of Malabars took possession of the place, and threw up fortifications, but they were soon expelled. The Portuguese visited Columbo in 1518, and soon after erected a fort; but the Singhalese, roused to resentment by the tyranny of the Portuguese, invested the fort with an army of 20,000 men, and besieged it for six months, when the Portuguese were enabled, by means of reinforcements from Goa, to disperse the Singhalese, and make their king sue for peace. The fort was at one time demolished in compliance with orders from Portugal, but a new fort was afterwards erected; and being firmly established in it, the Portuguese, by taking part in the intestine wars, gradually extended their influence over the whole island. In 1656 the Dutch wrested Columbo from them after a siege of seven months, and expelled them from the sea coast. In 1796 the Dutch surrendered it to the British.

COLUMBUS (a name latinized from the Italian Colombo, and the Spanish Colon) was born at Genoa†, about the year 1445 or 1446‡. His father, who was a wool-comber, sent him to Pavia, then the great school of learning in Lombardy; but Columbus having shown a taste for geometry, geography, and astronomy, or, as it was then termed, astrology, went to sea at fourteen years of age. In addition to the hardy encounters and dangers attending the sea-faring life of that age, he was often under the rigid discipline of an old relation, Colombo, who carried on a predatory warfare against Mohammedans and Venetians, the great rivals of the Genoese. In February, 1467, Columbus, in order to ascertain whether Iceland was inhabited, advanced 100 leagues beyond it, and was astonished at not finding the sea frozen. He also visited the Portuguese fort of St. George la Mina, on the coast of Guinea.

About the year 1470, he settled at Lisbon, then the great resort of travellers and navigators, whom Prince Henry§ highly encouraged. Here Columbus married the daughter of an Italian, called Patestrello, who had colonized and who governed the island of Porto Santo, and whose papers, charts, and journals, were highly serviceable to Columbus in his occasional expeditions to Madeira, the Canaries, the Azores, and the Portuguese settlements of Africa, and for the construction of maps and charts, which he sold to support his family, and his aged father at Genoa, as well as to defray the education of his younger brothers. Columbus resided also some time at the island of Porto Santo, which had not long been discovered, a circumstance which at a period of great excitement and expectation as to maritime discovery, kindled his mind to enthusiasm, which was heightened by the allusions in the Bible to the ultimate universal diffusion of the gospel, which Columbus hoped that he was predestined to extend to the eastern extremity of Asia. He considered his projected discoveries as only a means to this end, and also for supplying him with ample treasures to furnish an army of 50,000 foot soldiers and 5000 horse for the recovery of the holy sepulchre. Moreover the legends of the island of Cipango (Japan), of Mango (Southern China), and Cathay, the opinions of the antients, the travels of the moderns, the conjectured sphericity of the earth, its supposed smallness, and the imaginary prolongation of Asia to the east, all this presumptive evidence, added to the recent application of the astrolabe to navigation, gave him so firm a conviction of the practicability of crossing the Atlantic, and of landing on the eastern shores of Asia, that, after long delays, and repeated disappointments and struggles with poverty, he never made any abatement in those conditions which appeared to all the states* to whom he made proposals to be the extravagant demands of a mere adventurer. John II. of Portugal, after having referred the project to a maritime junto, and to his council, both of whom regarded it as visionary, nevertheless sent a caravel under the pretext of taking provisions to the Cape Verd Islands, but with secret instructions to try the route marked in the papers of Columbus. The pilots however losing all courage, put back to Lisbon, and ridiculed the scheme. Indignant at such duplicity, Columbus sought patronage elsewhere, and sent his brother Bartholomew to make proposals to Henry VII. of England.

In 1484 Columbus arrived at Palos de Moguer in Andalusia. Stopping one day at the Franciscan convent of La Rabida to beg some bread and water for his child, the guardian or superior, Juan Perez Marchena, passing by, and entering into conversation with the stranger, was so struck with the grandeur of his views, that he detained him as a guest, and sent for the physician of Palos, Garcia Fernandez, to discuss the project. Now, for the first time, it began to be listened to with admiration. Marchena, taking charge of the maintenance and education of the young son of Columbus, gave the father a letter of introduction to the confessor of Isabella, Fernando de Talavera. This expected patron treated the wandering petitioner as a dreaming speculator, and a needy applicant for bread. His humble dress, and his want of connexions and academic honours, formed, in the eyes of all the courtiers, an inexplicable contrast with his brilliant proposals and aspirations. But indigence, contumely, and indignities of all kinds, could not shake the perseverance of Columbus. At last, through Cardinal Mendoza, he obtained an audience of King Ferdinand, who referred the matter to a conference of learned monks, which was held in the convent of the Dominicans of St. Stephen at Salamanca. At the very opening of the discussion Columbus was assailed with biblical objections, against which no mathematical demonstration was admitted; but he met them on their own ground. He poured forth texts and predictions as mystical types of his proposed discovery. The inquiry however, after intentional procrastination, ended in an unfavourable report. After seven years wasted at the Spanish court in solicitation, occasional hope, and bitter disappointment, a connexion with a lady of Cordoba, Beatriz Enriquez, prevented his entirely breaking with Spain. She was the mother of his second son, Ferdinand, who became his historian, and whom he always treated on terms of perfect equality with his legitimate son Diego. Columbus was now about to apply to the French king, from whom he had received a letter of encouragement; when, returning for his eldest son, Diego, to La Rabida, the warm-hearted friar Marchena endeavoured to dissuade him from this project, sent again for the physician, Garcia Fernandez, and also called to their council Alonso Pinzon. This distinguished navigator not only approved of the projected voyage, but offered to engage in it with his money and in person, and even to defray the expenses of a new application at court.

The ardent friar lost no time in writing directly to Queen Isabella, and on her requesting a verbal explanation of the subject, he immediately went to Santa Fé, where she was then superintending with Ferdinand the close investment of Granada. Isabella, who had never heard the proposition urged with such honest zeal, enthusiasm, and eloquence, and who was besides more open to noble impulses than her husband, was at last moved in behalf of Columbus, but her favour was checked by her confessor Talavera, who, being now raised to the see of Granada, was more astonished than ever at the lofty claims of this indigent and threadbare solicitor. Those claims would be exorbitant in case of success, he observed; how unreasonable then would they appear in case of failure, which was almost sure to happen, and which would prove the gross credulity of the Spanish monarchs. More moderate, yet highly honourable and advantageous terms were offered to Columbus, but he considered them beneath the dignity of his enterprise, and determined once more to abandon Spain for ever.

---

* The town of Columbo is divided into four gravets, or districts.

† As he twice declares in his own will, but this fact, as well as the history of his early days, is involved in obscurity. His son Fernando, unwilling, from mistaken pride, to reveal the indigence and humble condition from which his father emerged, has left the biography of Columbus very incomplete.

‡ This is only inferred from two of his letters to Ferdinand and Isabella, in one of which he states that he went to sea at the age of fourteen, and in another, dated 1501, that he had been in maritime service nearly forty years.

§ This prince was far before his age. He established a naval college, and [illegible] an observatory at Sagres.

* Genoa, Portugal, Genoa again, Venice, France, England, and Spain.

Some friends, who considered his departure as an irreparable loss, once more remonstrated with Isabella, who at last offered her own jewels to defray the expenses of the expedition, and thus overcame the coolness of Ferdinand. Accordingly, a messenger was sent to overtake Columbus, who, after some hesitation, returned to Santa Fé. Stipulations were at last signed by Ferdinand and Isabella, at Granada, the 17th of April, 1492.

On Friday, the 3rd of August, 1492, Columbus, as admiral of the seas and lands which he expected to discover, set sail from the bar of Saltes, near Palos, with three vessels and 120 men, who were full of doubts and fears, and were partly pressed into the service. Two of these vessels were caravels, or light barques, no better than our river and coasting craft. This, however, Columbus considered an advantage, as it would afford him the means of examining shallow rivers and harbours. On the 5th, one of the vessels had her rudder broken; but fortunately, on the 6th, he perceived, as he expected, the Canaries, where he refitted. On the 6th of September he hastily quitted Gomera, to avoid three frigates which were sent against him by the King of Portugal from spite at seeing Columbus engaged in the Spanish service. As soon as the Canaries were out of sight consternation and despair spread among the crews, and the admiral was obliged to leave them in ignorance of the progress they were making[*]. He also forbade the variation of the needle to be mentioned to the crew, which he observed on the 13th of September, about 200 leagues W. of the island of Ferro, till it was noticed also by his pilots, when he succeeded in allaying their terrors with his ready ingenuity to meet any emergency, by ascribing the phenomenon to the movement of the pole star. The whole expedition being founded on the presumption of finding land to the west, Columbus kept steadily to this course, lest he should appear to doubt and waver, and never went in search of islands, which floating weeds, birds, and other indications, gave him reason to believe were not far off.

On the 20th of September the wind veered to the S.W.; and although unfavourable to the expedition, this circumstance cheered the dismayed crew, who were alarmed at its continuance from the E., which seemed to preclude all hope of their return. Repeated disappointments made the crews at last regard all signs of land as mere delusions. On the evening of the 10th of October they exclaimed more violently than ever against the obstinacy of an ambitious desperado, in tempting fate on a boundless sea; they even meditated throwing the admiral overboard, and directing their course homeward. Columbus, for the last time, tried to pacify them in a friendly manner; but this only increased their clamour. He then assumed a decided tone, acted in open defiance of his crews, and his situation became desperate. That he ever yielded to his men, rests on no other authority than that of Oviedo, a writer of inferior credit, who was grossly misled by a pilot of the name of Hernea Perez Matheos, an enemy to Columbus. Fortunately, on the 11th, the manifestations of land were such as to convince the most dejected. Accordingly, after the evening prayer, Columbus ordered a careful look-out, and himself remained on the high stern of his vessel from ten o'clock, when he had observed glimmerings of light, as he supposed on shore, till two in the morning, when the foremost vessel fired a gun as a signal of land having been discovered. Not an eye was closed that night, all waiting with intense feeling for the dawn of the 12th of October, 1492, which was to reveal the great mystery of the ocean, whether it was bounded by a savage wilderness, or by spicy groves and splendid cities, possibly the very Cipango, the constant object of the golden fancies of the admiral. With tears of joy, after fervid thanksgivings, Columbus kissed the earth on which he landed, and with great solemnity planted the cross in the new world at Guanahani, or San Salvador[*], one of the Gucayos, Lucayan or Bahama Islands. Those who had lately been most in despair were now the most extravagant in their joy. The most mutinous and outrageous thronged closest round the admiral, and crouched at the feet of a man who in their eyes had already wealth and honours in his gift.

The naked and painted natives, when they had recovered from their fright, regarded the white men, by whose confidence they were soon won, as visitors from the skies which bounded their horizon; they received from them with transport toys and trinkets, fragments of glass and earthenware, as celestial presents possessing a supernatural virtue. They brought in exchange cotton yarn and cassava bread, which, as it keeps longer than wheaten bread, was highly acceptable to the Spaniards.

On the 24th, Columbus set out in quest of gold and Cipango. After discovering Concepcion, Exuma, and Isla Larga, Cuba broke upon him like an elysium; he no longer doubted that this beautiful land was the real Cipango. When this delusion was over, he fancied Cuba, which, to the time of his death, he took for part of the mainland of India[†], to be not far from Mango and Cathay, so brilliantly depicted in his great oracle, Marco Polo. He next took Hayti, or Santo Domingo, for the ancient Ophir, the source of the riches of Solomon, but he gave it the Latin diminutive of Hispaniola, from its resembling the fairest tracts of Spain. Leaving here the germ of a future colony, he set sail homeward the 4th of January, 1493. A dreadful storm overtook him on the 12th of February. Columbus, fearing the loss of his discovery more than the loss of life, retired to write two copies of a short account of it. He wrapped them in wax, enclosed them in two separate casks, one of which he threw into the sea, and the other he placed on the poop of his vessel, that it might float in case she should sink. Happily the storm subsided, but another drove him off the mouth of the Tagus on the 4th of March; and although distrustful of the Portuguese, he was obliged to take shelter there. At last he landed triumphantly at Palos, the 15th of March, 1493. In his journey through Spain, he received princely honours all his way to Barcelona, where the court had gone. His entrance here, with some of the natives, and with the arms and utensils of the discovered islands, was a triumph as striking and more glorious than that of a conqueror. Ferdinand and Isabella received him seated in state, rose as he approached, raised him as he kneeled to kiss their hands, and ordered him to be seated in their presence.

On the 25th of September, 1493, Columbus left Cadiz on a second expedition, with seventeen ships and 1500 men. He discovered the Caribbee Islands, Puerto Rico, and Jamaica; and after repeated mutinies of his colonists, and great hardships, he returned against the the trade-winds to Cadiz, June 11, 1496. Having dispelled all the calumnies that had been accumulated upon him, Columbus embarked the 30th of May, 1498, at San Lucar de Barrameda, on a third expedition, with only six vessels. In this voyage he discovered La Trinidad, the mouths of the Orinoco[‡], the coast of Paria, and the Margarita and Cubagua Islands. On the 14th of August he bore away for Hispaniola to recruit his health. The dissensions which arose here, the calumnies of miscreants who had been shipped off to Spain, countenanced as they were by envious courtiers at home, the unproductiveness of the new settlement, and regret at having vested such high powers in a subject and a foreigner, who could now be dispensed with, induced Ferdinand, in July, 1500, to dispatch Francisco Bovadilla to supersede Columbus, and bring him back in chains. Vallejo, the officer who had him in charge, and Martin, the master of the caravel, would have taken his chains off; but Columbus proudly said, 'I will wear them till the king orders otherwise, and will preserve them as memorials of his gratitude.' He hung them up in his cabinet, and requested they should be buried in his grave. The general burst of indignation at Cadiz, which was echoed throughout Spain, on the arrival of Columbus in fetters, compelled Ferdinand himself to disclaim all knowledge of the shameful transaction. But still the king kept Columbus in attendance for nine months, wasting his time in fruitless solicitations for redress; and at last appointed Nicholas Ovando governor of Hispaniola in his place. With restricted powers and a broken frame, but with his ever-soaring and irrepressible enthusiasm, Columbus sailed from Cadiz again on the 9th of May, 1502, with four caravels and 150 men, in search of a passage to the East Indies near the Isthmus of Darien, which should supersede that of Vasco de Gama. Being denied relief and even shelter at Santo Domingo, he was swept away by the currents to the N.W.; he however missed Yucatan and Mexico, and at last reached Truxillo, whence he coasted Honduras, the Mosquito shore, Costa Rica, Veragua, as far as the point which he called El Retrete, where the recent westward coasting of Bastides had terminated. But here, on the 5th of December, he gave up his splendid vision, and yielded to the clamours of his crews to return in search of gold to Veragua, a country which he himself mistook for the Aurea Chersonesus of the antients.

---

[*] He adopted throughout the voyage the stratagem of keeping two reckonings, one true and private, for his own guidance, the other merely for the crews, to keep them in ignorance of the great distance they were advancing.

[*] Navarrete contends that it must have been Turk Island, another of the same cluster, although this supposition is at variance with all the particulars of San Salvador, which are accurately described in the journal of Columbus.

[†] Owing to this mistake, the appellation of Indians was extended to all the Aborigines of the Americas.

[‡] He imagined this river to proceed from the tree of life in the midst of Paradise, the situation of which was then supposed to be in the remotest parts of the east.

Finally, the fierce resistance of the natives and the crazy state of his ships forced him, at the close of April, 1503, to make the best of his way for Hispaniola with only two crowded wrecks, which, being incapable of keeping the sea, came, on the 24th of June, to anchor at Jamaica. After famine and despair had occasioned a series of mutinies and disasters far greater than any that he had yet experienced, he at last arrived, on the 13th of August, at Santo Domingo. Here he exhausted his funds in relieving his crews, extending his generosity even to those who had been most outrageous. Sailing homewards on the 12th of September, he anchored his tempest-tossed and shattered bark at San Lucar, the 7th of November, 1504. From San Lucar he proceeded to Sevilla, where he soon after received the news of the death of his patroness Isabella. He was detained by illness till the spring of 1505, when he arrived, wearied and exhausted, at Segovia, to have only another courtly denial of redress, and to linger a year longer in neglect, poverty, and pain, till death gave him relief at Valladolid on the 20th of May, 1506. Thus ended a noble and glorious career, inseparably connected with the records of the injustice and ingratitude of kings. To make some amends for the sorrows and wrongs of this great man, his remains received a pompous funeral, and his grave and coat of arms the following motto:—

'A Castilla y a Leon
Nuevo mundo dio Colon.'

Although Sebastian Cabot discovered Newfoundland and Labrador in June, 1497, and Columbus did not touch the American continent till he visited the coast of Paria in August, 1498, Columbus, however, first reached Guanahani, and what may properly be denominated the Columbian Archipelago, and is really the discoverer of the New World.

The voyage of one Antonio Sanchez from the Canaries to Hayti in 1484, mentioned by the Inca Garcilaso and some other Spanish writers, is regarded as a fable. The accounts however of Spaniards and Portuguese who had sailed westward so far as to perceive indications of land, were useful to Columbus, according to his own avowal. Ferdinand and Isabella, in a written declaration of the 4th of August, 1494, ascribe the new discoveries to Columbus. Amerigo Vespucci, whose name was afterwards given to the new hemisphere, did not see it till he accompanied Ojeda, as a pilot, to the coast of Paria in 1499.

The following are the principal authorities for the Life of Columbus:—'Navigatione del Re di Castiglia delle Isole e Paesi nuovamente ritrovati,' and the Latin translation, 'Navigatio Christophori Colombi,' Vicenza, 1507; 'Itinerarium Portugallensium,' Milan, 1508; Grinæus, 'Novus Orbis Regionum,' Bâle, 1533; Life of the Admiral, by his son Fernando, Oviedo; 'Chronicle of the Indies,' Sevilla, 1535; Manuscript History of Fernando and Isabella, by the curate of Los Palacros; Manuscript History of the Indies, by Las Casas; 'Letters and Decades of the Ocean,' by Peter Martyr d'Anghierra, or Angleria; Herrera, 'History of the Indies;' 'Robertson's America;' Churchill's Voyages, vol. ii.; Navarrete, 'Relacion de los quatro Viajes de Cristobal Colon;' Irving's Life of Columbus.

COLUMBUS. [Ohio.]

COLUMELLA, LU'CIUS JU'NIUS MODERATUS, the author of one of the most valuable works on Roman agriculture, if not himself a native of Gades (Cadiz), sprung from a family belonging to that town, which had been long most intimately connected with Rome. In several parts of his work he speaks of a paternal uncle, Marcus Columella, who had lived in Baetica (Andalusia), and had been well known as an intelligent agriculturist. In particular he speaks of his success in the improvement of the breed of sheep by the introduction of rams from Mauretania, and it has been suggested that the celebrated stock of the Merinos owes its origin to this importation. The author himself possessed an estate in the country of the Ceretani (La Cerdaña), near the Pyrenees, where he was eminently successful in the growth of the vine. When he wrote his work, he appears to have been residing either at Rome, or in the neighbourhood; but he had a personal knowlege of many parts of the Roman empire. He himself mentions a residence of some length in Cilicia and Syria (ii. 10, 18), but without stating the object which carried him into that part of the world. The period at which he lived and wrote may be most safely deduced from his own writings. On the one hand he mentions his having been present at a conversation on agriculture in which L. Volusius took part (i. 7, 3), and the terms he uses imply that many years had since elapsed. Now the death of this very man happens to be specially noticed by Tacitus at the end of the year A. D. 20 (*Ann.* iii. 30). Again he speaks of Seneca as still living (iii. 3, 31); and the tragical death of Seneca, it is well known, occurred in the year 66. He speaks moreover of Varro as preceding him by two generations. He was born therefore about the beginning of the Christian æra.

The work of Columella is addressed to Publius Silvinus, and consists of twelve books: the two first on the choice of a farm and farm-house, the selection of slaves, the cultivation of arable and pasture land: the three next on the cultivation of the vine, olive, and fruits of the orchard, &c.; the sixth and seventh, on the ox, horse, mule, ass, sheep, goat and dog, that is, the shepherd's dog and the house dog, for he specially excludes the sporting dog, as interfering with, instead of promoting, the economic management of a farm. The eighth book treats of the poultry-yard, and the ninth, of bees. The next, which has for its subject the vegetable and flower garden, presents the unusual spectacle of a poem in the middle of a prose work. This form was selected by Columella at the pressing solicitation of his friend Silvinus, and the poem was avowedly put forth as a supplement to the Georgics of Virgil, in answer to the challenge of the Mantuan bard:

'Verum hæc ipse equidem spatiis inclusus iniquis
Prætereo, atque aliis post me memoranda relinquo.'

In the eleventh book the author is again on the terra firma of prose, and gives us in three long chapters, not very closely connected, the duties of a bailiff, a farmer's almanack, and the vegetable garden. This book is sometimes entitled the 'Bailiff' (Villicus); as the last bears the name of the 'Bailiff's Wife' (Villica), and treats of the indoor duties, the making wine and vinegar, preserving fruits, &c.

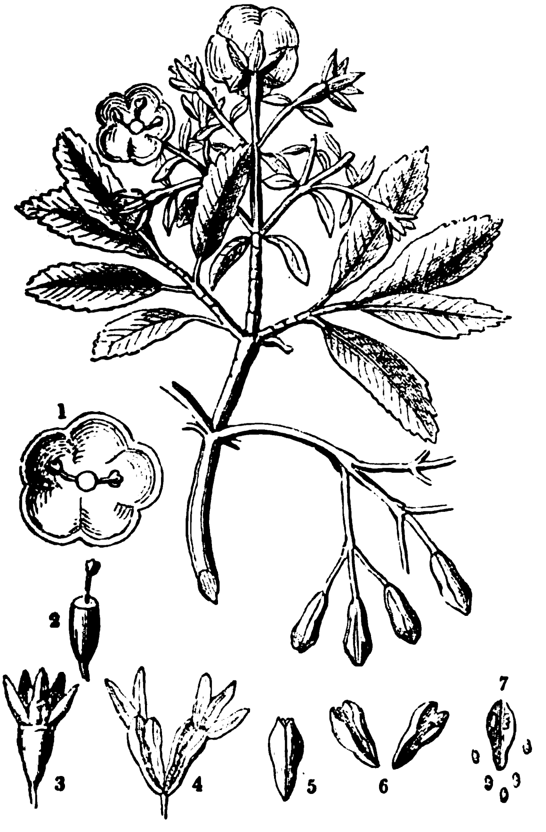
In the composition of this work, Columella has made free use of the Roman writers on agriculture who preceded him. Among these we may particularly mention Cato the Censor, Terentius Varro, his own contemporaries; Cornelius Celsus and Julius Atticus; and lastly, Julius Græcinus, the father of Agricola, who seems to have shown his predilection for the science by the name he selected for his son. But the author of whom he speaks in the highest terms, and to whom he most willingly appeals, is Mago the Carthaginian, whose work on agriculture, as he tells us, containing eight-and-twenty books, was translated from the Phœnician into Latin, under a special decree of the Roman senate. The latinity of Columella has nearly all the purity of the Augustan age; but wherever his subject gives him an opportunity, he discovers a taste for that sentimental and declamatory style which distinguishes the writers of the first and second centuries. His poem is deficient in all those qualities which give grace and beauty to the Georgics. Columella is often cited by Pliny the Elder in his 'Natural History,' but generally with an expression of dissent. He is also quoted by Vegetius and Palladius.

But the treatise on agriculture by the latter appears to have superseded Columella's work, and to have thrown it altogether into oblivion. Besides the great work of Columella, which we have described, there is a single book entitled, 'De Arboribus,' in which reference is made to a preceding book now lost. These two appear to have been a portion of an early edition of the work on agriculture, probably in four books, which being afterwards enlarged, swelled into the twelve we now possess. Accordingly the matter of the 'De Arboribus' will be found with some alterations and many additions, in the third, fourth, and fifth books of the greater work; and Cassiodorus actually speaks of sixteen books written by Columella. In ignorance of this, the writers of many of the MSS, as well as the early editors, have inserted the minor treatise after the second book of the more complete work, thus causing many contradictions and great confusion in the numbers of the following books.

The writings of Columella have generally been published together with the works of the other authors 'De Re Rustica.' The chief editions are these: 'The Princeps,' Venice, fol. 1472; Bologna, fol. 1494; by Aldus, 8vo., 1513, or rather 1514; by R. Stephens, 8vo., 1543; by Gesner, Leipzig, 2 vols. 4to., 1735; and what may now be looked upon as the best, the edition by J. G. Schneider, 4 vols. 8vo, 1794—7. We are not acquainted with any English translation of Columella.

COLUME'LLA, the central part or axis in the theca of a moss, around which the spores are arranged without having any definite connection with it. Also the axis of any kind of fruit when separate from the carpels: in the latter case it is a hardened state of the growing point.

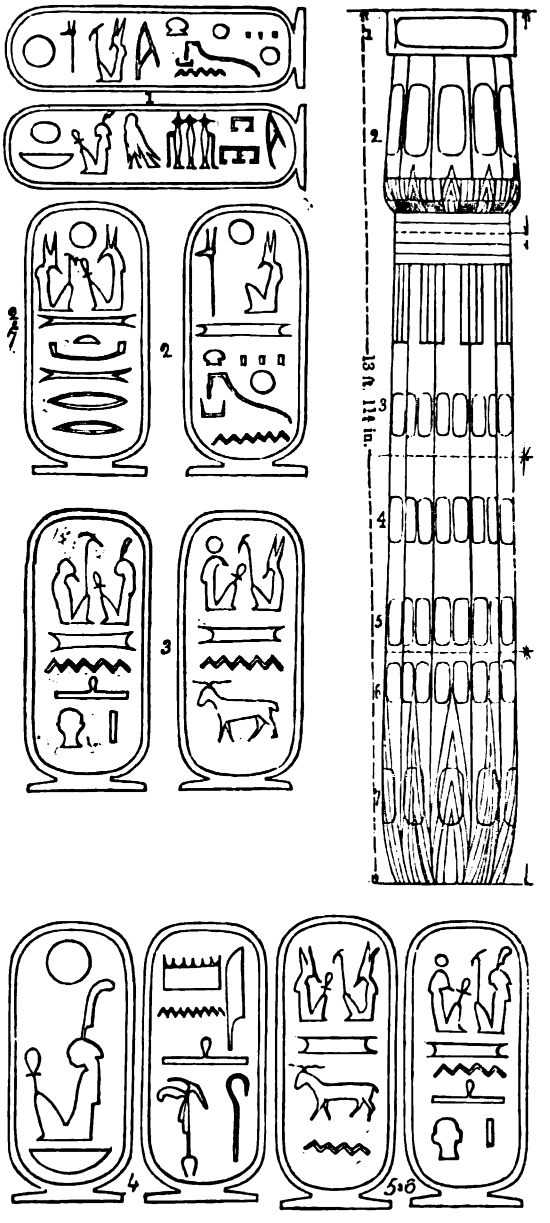
COLUMELLIA'CEÆ, a small diandrous order of monopetalous Exogens, with a superior five-parted calyx, a rotate corolla, three-lobed anthers bursting outwards, a two-celled ovary with an indefinite number of ovules and a capsular fruit. They are South American and Mexican bushes, looking like monopetalous Onagraceous plants, of doubtful affinity, and of no known use. (Lindley's *Natural System of Botany*, ed. 2, p. 240.)



[Columellia oblonga.]

1. A flower seen from above. 2. The ovary, style and stigma. 3. The half-ripe fruit. 4. The fruit opening, with the calyx adhering. 5. The pericarp separated from the calyx. 6. Valves of the pericarp. 7. One valve and seeds.

COLUMN, from the Latin columna. The column is a shaft of wood, stone, or iron, in the form of a truncated cone, a little swelled from the straight line at about one-third its height from the lower extremity. this swelling is called the entasis. The column is furnished with a base at the foot and a capital at the head of the shaft. Columns are of various proportions and kinds: circular on the plan, and rarely polygonal. The Romans had five models of columns, which were called orders; but the Greeks, from whom the Romans appear to have derived their architecture, only three. The Egyptians used columns, but they were very different in their form and proportions from both the Roman and Greek examples.



[Egyptian Column in the British Museum.]

The elliptical figures are the cartouches on the column, drawn to a larger scale. The height of the column is 13 ft. 11½ in.

The five orders are the Corinthian, Ionic, and Composite, which is a mixture of the two former; and the Doric and the Tuscan—two orders very similar in appearance and character to each other.

The Greek Corinthian, Doric, and Ionic differ from the Roman. The proportions of the orders vary slightly in almost every example of antiquity; but the distinguishing features are the capitals. The bases also vary in proportion, and sometimes in the profiles of their mouldings; but this is not so apparent to an ordinary observer as the difference in the capitals of the orders.

The Corinthian capital consists of the leaves of the acan-

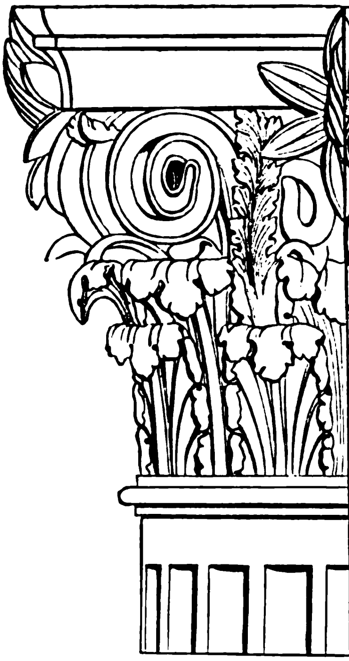
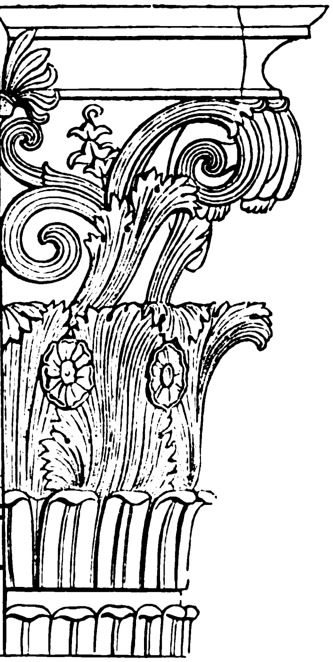
TUSCAN. ROMAN DORIC. ROMAN IONIC. CORINTHIAN. COMPOSITE.

(Drawn to the same scale of two Modules, by dividing the diameter into two parts, and each part into thirty parts or minutes.)

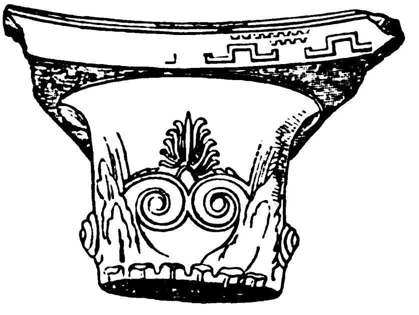


[Half the Corinthian capital of the Temple of Vesta, at Tivoli.]



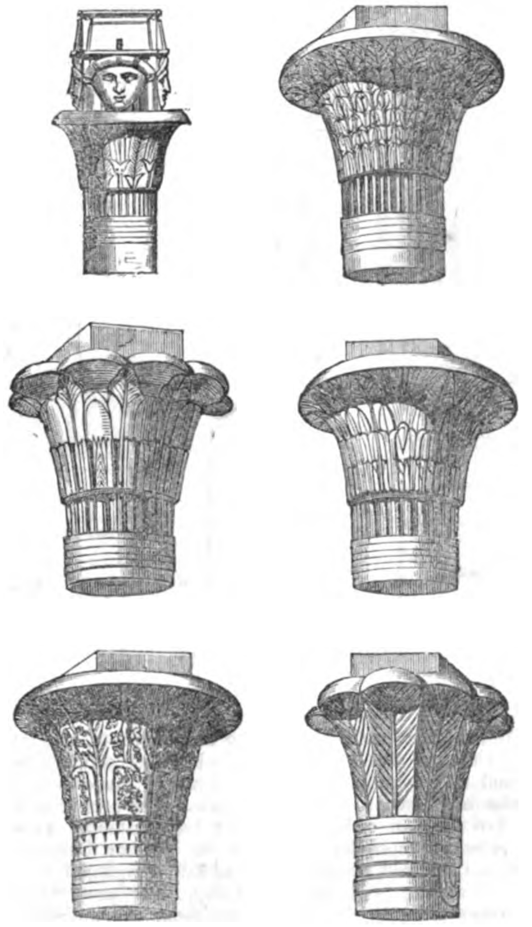
[Half the Corinthian capital from the monument of Lysicrates, at Athens.]

thus, with two spiral horns at each of the four angles of the abacus. In the centre between these horns are two smaller spirals attached to the bell of the capital; under these are two rows of acanthus leaves regularly disposed, eight being placed in each row, and eight large double leaves supporting the angular horns, called also volutes. These are the leading features of the Corinthian capital, although some are more ornamented than others, and have enriched details about the abacus and the bell, which others have not. The most striking difference between the character of the Greek and Roman foliage of the Corinthian column is this: the leaves of the Greek have angular points, and are almost straight on the sides; the Roman are rounded on the sides; the section of the hollow of the former is angular, while the latter is either a segment of a circle, or formed of two segments of a circle meeting in the centre of the hollow of the points of the acanthus leaf. The Greek leaves may be said to have more of the natural character of the acanthus, or the thistle, while the Roman is more artificial, and consequently less like the model from which the Greeks drew their capital. There are examples of the Greek Corinthian capitals, although much mutilated, in the Elgin collection in the British Museum; and casts of the Roman examples from the temple of Jupiter Stator, Mars Ultor, and the Pantheon, also in the British Museum. The bell of the Corinthian capital may be clearly understood from the annexed drawing of the mutilated single Corinthian capital



[Bell of a Corinthian Capital, a fragment from the Temple of Apollo, at Bassæ.—From the 4th vol. of Stewart's 'Athens,' published by Priestly and Weale, London.]

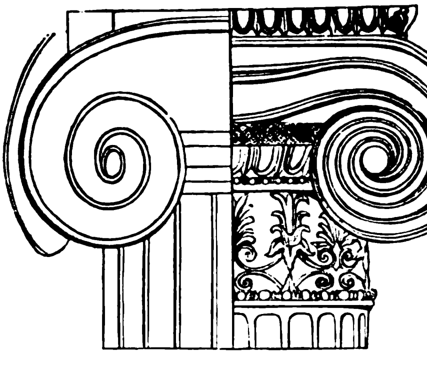
found in the Temple of Apollo at Bassæ, near Phigaleia; and the accompanying drawings of Egyptian capitals, from the French work on Egypt, will shew better than any elaborate description the strong resemblance of the Egyptian capital to the bell of the Corinthian capital, as we meet with the latter in the Temple of Jackly near Mylasa, and the Choragic monument of Lysicrates at Athens. The



[Egyptian capitals.]

order of the Temple of Vesta at Rome, which very much resembles the order of the Temple at Jackly, was most probably copied from it. Among other peculiarities, it has the same defect of the leaves projecting beyond the line of the shaft, and is the only building of the Corinthian order, in Rome, which has a Greek character. Some Greek Corinthian capitals have only one row of acanthus leaves, and are without the horns under the abacus, the bell being decorated with flat leaves called water-leaves, as in the Tower of the Winds at Athens.

The Ionic column is characterized by the two large spirals or volutes on two of its faces, connected under the abacus. The other sides connect these faces at right angles by a kind of baluster placed horizontally. Beneath this baluster and the astragal surmounting the top of the shaft of the column is the neck of the capital, which in some Greek examples is richly decorated; the baluster is also occasionally enriched. In some Ionic capitals all the faces of the volutes are conjoined at the extremities, the faces being curved inwards as in the Temple of Apollo at Bassæ. Ionic columns placed at the angles of porticos have sometimes the volute ingeniously formed at the angle, so as to present a voluted face either ranging with the volutes of the portico, or with the volutes of the columns at the side of the portico. The angle column of St. Pancras Church, London, has the angular faces curved. The angular volutes in some Roman examples are formed of two half volutes placed at right angles to each other. The bases of the Ionic vary perhaps more than any other order. In Roman examples the Attic base is employed.

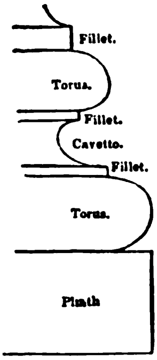


[Half the Ionic capital of the order employed in the cella of the Temple of Apollo at Bassæ.] [Half the capital of the Erectheum.]

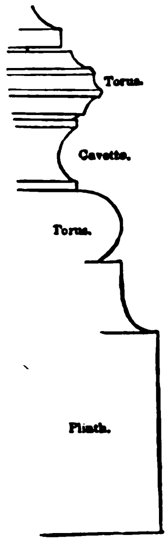
The Composite column, as its name implies, is a compound. It is formed of the Corinthian and Ionic, but partakes more of the Corinthian character and proportions.

The Roman-Doric and Tuscan columns are shafts with moulded capitals and bases, the Doric only having a slight decoration of rosettes and buds in the neck of the capital, and some trifling additional mouldings. The Grecian Doric differs from the Roman both in proportion and in the mouldings of the capital, in the flutings being without fillets, and in its being almost always without a base.

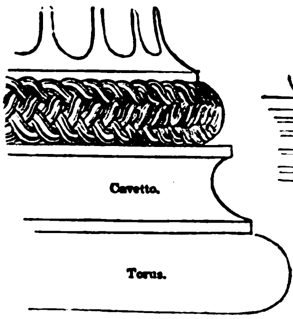
An order includes the column with the whole of the entablature, or the superstructure raised on it, which is divided into architrave, frieze, and cornice.



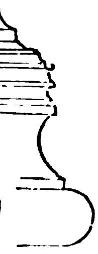
[Attic Base.]



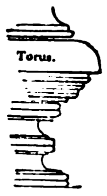
[Ionic Base at the Propylæa of Eleusis.]



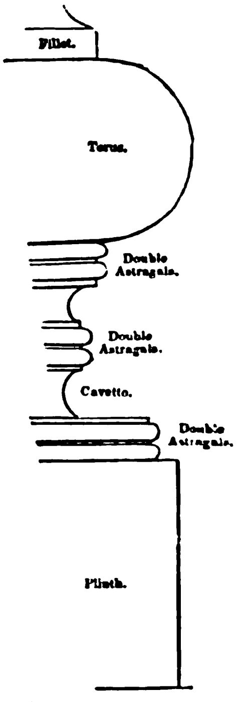
[Base of the Erectheum.]



[Base of the Minerva Polias.]



[Base of the order of the Temple of Apollo Didymæus.]



[Profile of the bases of the columns employed in the Temple of Minerva Polias, at Priene.]

All the great architects of the cinque cento, and after them those of the later Italian and French schools, have differed in the proportions and details of the orders, but for the most part in a trifling degree. The proportions of the five Roman orders which we have adopted here as our rule are those laid down in Sir William Chambers's Architecture, and which are generally employed by the English architects of the present day. The proportions of the orders used by the Greeks are from the authority of Stuart. The measure by which the proportions of the orders are determined, is the diameter of the base of the shaft of the column, which is divided into two parts called modules, and each module is divided into 30 parts called minutes. This scale is in general use in all countries which derive their architecture from the Greeks and Romans.

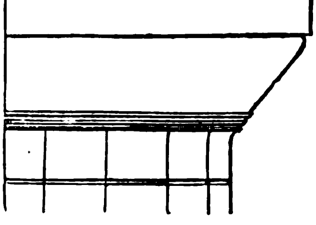
Thus the height of the shaft of the Tuscan order, from the upper line of the fillet of the base to the upper line of the astragal of the neck of the column, is 12 modules or semi-diameters high; the base, including the plinth, is 30 minutes; the capital, 30 minutes; the architrave, 31½ minutes; the frieze, 31½ minutes; the cornice, including the bed-mould or ogee, 42 minutes; and the projection of the cornice, 42 minutes. The shaft of the Doric order is 13 modules, 28 minutes; the base, 30 minutes; the capital, 32 minutes; the architrave, 30 minutes; the frieze, 45 minutes; and the cornice, 45 minutes. The projection of the cornice is 57 minutes. The shaft of the Ionic order contains 16 modules, 9 minutes; the base, 30 minutes; the capital, from the upper line of the astragal, 21 minutes; the architrave, 40½ minutes; the frieze, 40½ minutes; and the cornice, 54 minutes. The projection of the cornice is 54 minutes. The Corinthian order has the shaft 16 modules, 20 minutes; the base, 30 minutes; the capital, 70 minutes; the architrave, 45 minutes; the frieze, 45 minutes; the cornice, 60 minutes;

and the projection, 58 minutes. The Composite order is similar in its general proportions to the Corinthian; and the columns of the Roman orders diminish in diameter about one-sixth, that is, are 50 minutes at the upper diameter of the shaft.[*] The Greek Doric varies very much in its proportions. The Doric of the Parthenon has the shaft and capital 10 modules 8 minutes high, and the entablature 3 modules 15 minutes. For a scale of the proportions of the leading features of some of the best known examples of antiquity, see the end of this article.

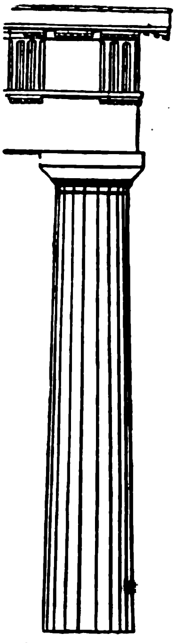
The Tuscan order, which is simple in its design, has a base formed of a plinth or squared piece of stone as a foundation, and a torus above it, surmounted with a fillet. The shaft is terminated with a fillet and an astragal, on which the capital is set, consisting of a necking (a prolongation of the shaft) and an ovolo moulding supporting the squared abacus, which is surmounted with a fillet. The architrave is a plain face with a broad fillet. The frieze also is a plain face. The cornice consists of an ogee, a fillet, an ovolo forming the bed-mould of the cornice, which consists also of the corona and fillet, surmounted with a cymatium.

The Roman Doric, resembling in some particulars the Tuscan, is however very much richer. The Doric base consists of a plinth, a torus, a hollow moulding with a fillet above and below it; on the upper fillet is another torus and fillet, from which rises the shaft, curved where it springs from the fillet.[†] This is the Attic base, which is most commonly used in all the orders except the Tuscan. The shaft of the Doric is terminated like the Tuscan, and from the summit springs the capital with a neck enriched with rosets and buds. Above the necking are three flat annular rings or fillets, then an ovolo moulding surmounted with the abacus, which is finished with a small ogee moulding and fillet. The architrave is a plain face, with a flat band (*tænia*) and a fillet under the triglyph, with six guttæ or drops under the fillet. The frieze is divided into compartments with a triglyph over each column and one or more between, according to the width of the intercolumniation. The triglyphs which project slightly from the face of the frieze are channelled with angular channels and two half channels at the sides of the triglyph. The metope, or space between two triglyphs, is square or nearly so; this, however, depends on the intercolumns. The triglyphs are bound together by a facia, surmounted by a small fillet under the bed-mould of the cornice, which is an ovolo moulding or an ogee. Over this is the mutule band with the mutules, square in form, projecting over the triglyphs; an ogee surmounts the mutules and the mutule band. The mutules support the cornice, consisting of the corona, an ogee and fillet, and a cavetto or hollow moulding. The soffit or under-side of the cornice is sometimes enriched with pannels, and guttæ are placed under the mutules. The Doric of the theatre of Marcellus at Rome has dentils with an ogee bed-mould in the cornice in lieu of the mutules; and the basilica by Palladio at Vicenza is without either mutules or dentils, having instead of them a bold ogee and ovolo moulding, and the architrave divided into two faciæ.

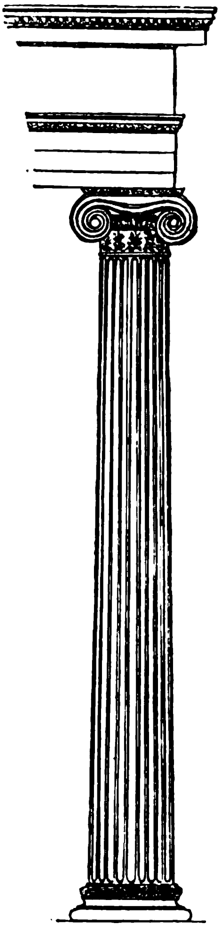
The Greek Doric differs considerably from the Roman, being almost always executed without a base. The flutings of the shaft are twenty in number without fillets; some examples are fluted only at the upper and lower extremities. The capital consists of a solid-looking abacus without any moulding above it, but supported by a very elegantly-curved echinus-moulding, which swells gradually out of the line of the shaft, being bound round by three annulets or rings near the top of the shaft, and on the under extremity of the echinus. A part of the shaft is also cut off by a sinking, or channel, cut into the shaft, forming the necking of the capital. The features of the entablature are very simple. [CIVIL ARCHITECTURE.] The triglyphs are not very dissimilar in the Roman and Greek Doric, except in the setting them off on the frieze. In the Roman they are invariably set over the centre line of each column, the angle of a building being terminated by a portion of a metope. In the Greek the triglyph is invariably commenced at the angle of the building, and not over the centre line of the column generally.



[Half the capital of the Parthenon at Athens.]



[Greek Doric order of the Parthenon.]



[Ionic order of the Erectheum at Athens.]

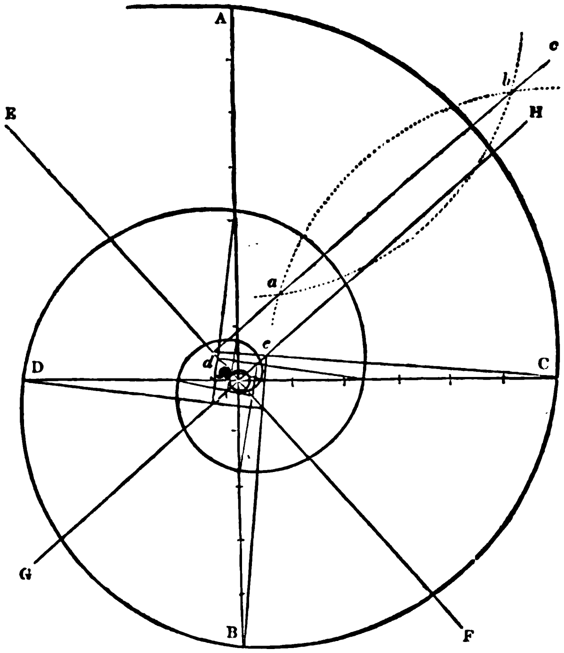
The Roman Ionic has an Attic base. The capital is formed with two volutes on two faces, and the volutes are connected by horizontal lines, though sometimes, like the Greek, the curved line is employed. The abacus is formed of a fillet and an ogee. Under the horizontal lines connecting the volutes is an echinus and astragal or bead-moulding enriched. The architrave is divided into two faciæ: the upper face is surmounted with a fillet and ogee enriched, and the lower with a small echinus, also enriched, having a narrow fillet underneath it. The frieze is usually plain, though the temple of Fortuna Virilis at Rome has a meagre decoration. The cornice is supported by an ogee moulding and dentils surmounted with a fillet, a bead moulding, and a large enriched echinus moulding. The cornice itself consists of a corona with a small ogee and fillet, on which is placed a cymatium. The volutes of the capital are connected at the sides by a pulvinus, or cushion, commonly called the baluster of the Ionic order. The Greek Ionic varies in its proportion, and is superior in beauty to the Roman example. The method of drawing the Roman volute called Goldman's volute, is described in Sir William Chamber's Architecture.

The following is a very accurate method of drawing the

[*] By a reference to the proportions of some of the columns of antient edifices at the end of this article, some variations from this proportion will appear.

[†] The lower diameter of the shaft of a column is always measured from the point where this curve ends, and is joined to the straight line of the shaft.

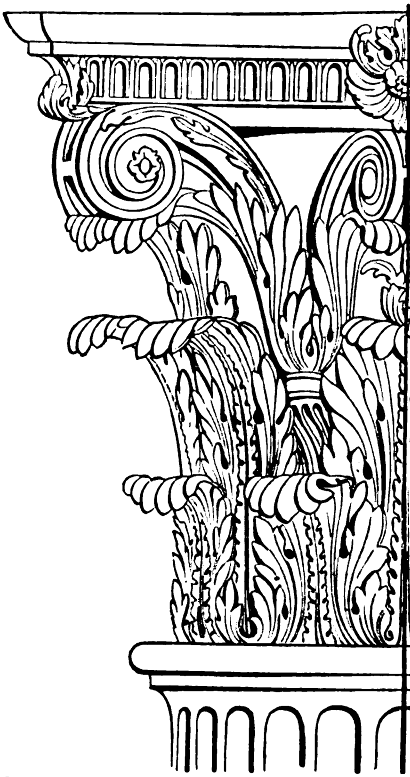
Greek volute similar to the form of the volute of the Erectheum or Minerva Polias at Athens. Divide any perpendicular height, A B, into 12 equal parts. Through the 7th division *g* from the top, draw the line C D at right angles to A B. Then upon the line C D, from the centre *g*, set off towards C six of the seven divisions between A and *g*. Draw the lines G H and E F, at angles of 45 degrees to the lines A B and C D respectively. Bisect the line joining A and C by *b a*, and produce it till it cuts E F in *d*. Then from *d*, as a centre, with the radius *d* A or *d* C, describe the quadrant A C of the volute. Then join C *d*, cutting the line G H in *e*; from the point *e* describe with the radius *e* C or *e* B the quadrant C B, passing through B, the extremity of the line A B; and proceed in this manner with all the quadrants till you touch the centre. The centres of the segments A C, C B, B D, &c., are always found on the diagonal lines E F and G H.



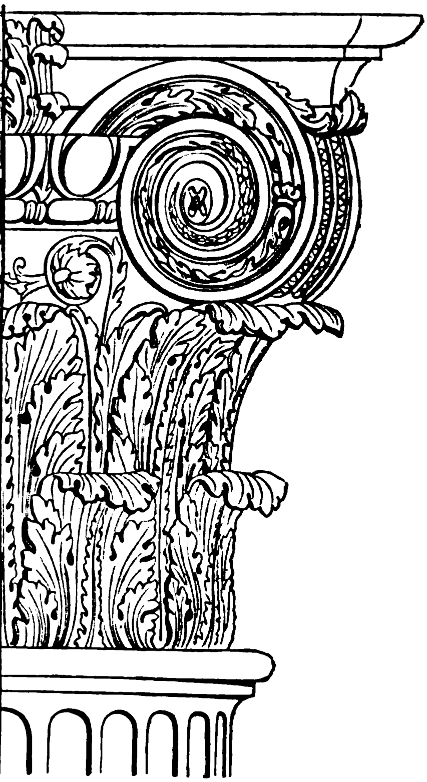
[Method of drawing the spiral forming the volute of the Greek Ionic of the Erectheum and Minerva Polias Temples, at Athens.]

The best examples of the Roman Ionic order are fluted, with twenty-four flutings, or semicircular channels, divided by a narrow fillet, which is part of the surface of the shaft of the column. Some Greek examples, as at Basea, have only 20 flutings, and are without fillets.

The general proportions of the Corinthian and Composite are the same, and they differ but slightly in their mouldings and enrichments. The base of both Corinthian and Composite is the Attic. The flutings of the shaft are, as in the Ionic, twenty-four, and divided by fillets. The capital is composed of two rows of acanthus leaves, eight in each row, and the upper row is placed between and over the divisions of the lower row. Four spiral volutes in each face rise out of two bunches of the acanthus leaf, and two of them are connected at the angles, and support the abacus formed of a cavetto and fillet, and an echinus, which are, except the fillet, sometimes enriched. The face of the abacus is formed of the segment of a circle, whose extremities are supported by the spiral horns, or volutes. The connected ends of the abacus form a narrow face, round which the mouldings are continued, although in some rare instances these ends are pointed by the intersection of the two curved faces of the abacus. The leaves and volutes are carved round what is a continuation of the shaft, formed into the shape of a bell reversed. The lower row of leaves generally follow the line of the shaft, which is considered the best system of setting them off round the bell, although the Temple of Vesta at Rome has the leaves projecting beyond the shaft, and Inigo Jones has adopted this system in the Banqueting-house at Whitehall. The Corinthian architrave is divided into three faces, the Composite into two. The upper face is surmounted with an astragal and ogee enriched with a fillet: the middle face has above it a small enriched ogee, and the lower face an enriched bead. The frieze is enriched with figures or ornaments. The cornice is distinguished by its modillions and dentils; the latter are supported by an ogee and astragal enriched: the former by an enriched echinus and astragal. The modillion, which is set at intervals under the corona, will be better understood by the annexed view of a modillion of the Temple of Jupiter Stator, showing also the soffit, or under-side of the corona, with the enriched pannel between the modillions. The modillions support the corona, which

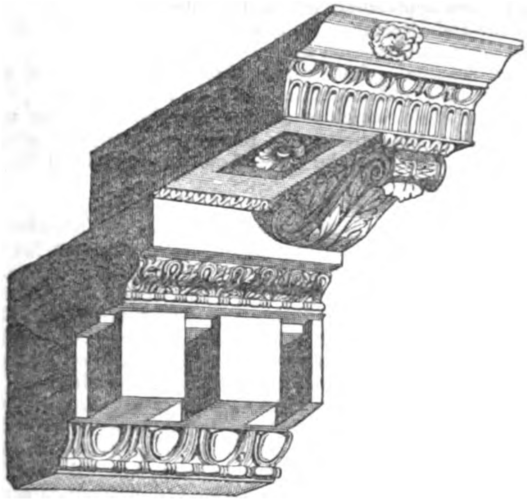


[Half the Corinthian capital, from Sir Wm. Chambers.]



[Half the Composite capital, from Sir Wm. Chambers.]

is terminated with a cymatium, and this moulding, in the example before us, is decorated with lions' heads.



[A Modillion or Console of the cornice of the Temple of Jupiter Stator at Rome.]

In the Composite, mutules are sometimes employed instead of the Corinthian modillion. The orders are sometimes set on pedestals, consisting of a square shaft, called the die, with a moulded base set on a deep plinth. The die is surmounted with mouldings forming a capital, but in reality resembling more the cornice of an entablature. Chambers allows, for the proportion of the die of the Tuscan pedestal, two modules, twenty-four minutes; for the Doric, three modules, six minutes; the Ionic, three modules, eighteen minutes; and the Corinthian and Composite, four modules. The bases and capitals are respectively—Tuscan, base twenty-eight minutes, capital fourteen minutes; Doric, base thirty-two, and capital sixteen minutes; Ionic, base thirty-six, and capital eighteen minutes; and Corinthian, base forty, and capital twenty minutes.

Greek mouldings vary from the Roman, and are remarkable for being almost invariably drawn by the hand, and not formed, as in the Roman examples, of parts of circles struck with the compasses.

The flutings of columns vary in the depth and form of their curves; some, as in the Doric orders, are flat segments, without fillets between them, others are deep segments and semicircles, and others are semi-elliptical, and sometimes more than semi-elliptical, on the plan, as in the Jupiter Stator. Some columns of antiquity are decorated with spiral flutes, and some with leaves, as in the Temple of Clitumnus, and in a fragment in the British Museum. Townley Marbles, room IX.

The method of drawing the entasis of the columns employed in Roman architecture is described by Chambers, p. ii. of the Preface. It is done by means of a sliding rule, called the rule of Nicomedes.

Some account of the entasis of columns, by Mr. Jenkins, is given in the 4th vol. of Stuart's 'Athens,' with comparisons of the entasis of several columns. The Greek entasis is more subtle than the Roman.

We may here observe, generally, that the principle of a base is support, which is admirably shown in the Attic base, where the two tori are proportioned and arranged, with the graceful sweep of the cavetto or hollow moulding between them, to sustain the shaft. The hollow moulding gives additional height to the base, and the profile is in no part within the perpendicular line of the shaft, which would give it a weak appearance. The annexed variety of bases, from Greek examples, present some of the beauties and some of the defects even of Greek architecture. The base of the Apollo Didymæus shows weakness, and the torus of the Minerva Polias, at Priene, appears too heavy for the delicate astragals and cavettos beneath.

Some columns, instead of being fluted the whole height of the shaft, are, for about one-third from the base, made polygonal, each side being the width of the flute. This is particularly the case at Pompeii, where the Doric columns are often very slender. In the internal order of the Pantheon, the flutings are filled with cabling about one-third of their height. Cabling is a carved band projecting out of the fluting.

Vitruvius makes the height of the Doric (Roman) seven times the diameter; the Ionic, 8¼; and the Corinthian, two-thirds higher than the Ionic, or nine diameters and one sixth. The proportions of Palladio and Vignola differ; the latter are, we believe, preferred by the French school. See the Architecture of Palladio and Vignola. The proportions of the columns given above, are from Stuart's 'Athens;' Taylor and Cressy's 'Rome;' 'Ionian Antiquities;' and 'Unedited Antiquities of Attica.'

In studying these works the student should be guided by the figures denoting the dimensions rather than by the outlines.

COLUMN, a body of troops consisting of one battalion or more, drawn up with the several divisions behind one another, so as to present a narrow front to the enemy: it is said to be in close or open order, according to the breadths of the intervals between the companies or battalions of which it is composed.

The armies of the Greeks and Romans may be said to have been generally formed in columns both for attack and defence. The troops having nothing to fear, in their 'serried' ranks, from a distant artillery, could, by such a disposition, most effectually overwhelm the enemy, or, if on the defensive, resist the shock of his assault: and even after the use of fire-arms was introduced in war, and the successes of Gustavus Adolphus had proved the advantages of a different order of battle, military men with difficulty overcame the prejudices which attached them to the practice of keeping the troops in dense array. The Chevalier Folard, in his 'Traité de la Colonne,' has given at great length every argument that can be urged on behalf of the practice: he compares the column to a moving rampart capable of resisting every effort of the enemy to penetrate through it, and in this respect he considers it far preferable to a hollow square: he compares it also to a torrent hurrying away the enemy by its fearful impetus. He observes besides that it may be deployed and re-formed quickly, and that it can easily accommodate itself to any evolution which may be required. Lastly, he combats the opinion that its order will be destroyed by the effects of the enemy's fire; alleging that while the column is in motion, a distant cannonade is nearly harmless.

Such also are nearly the arguments lately used by Bulow and Jomini in favour of the system of attack by columns. The opinions of these tacticians are strengthened by the general practice of Napoleon, which was to concentrate a great body of troops opposite some one point of an enemy's line, and lead them to the attack. It must not however be forgotten that this method has not always succeeded; according to Rogniat, the defeat of the French at the battle of Esling was caused by the failure of an attack made in that manner against the centre of the Austrian line. In Spain, and on the field of Waterloo, their columns were invariably repelled by the firm resistance opposed to them by the British line of battle.

It is evident however that the advantage of attacking in columns will be great when the force of the enemy is too much diffused, and when his line has been previously disordered by a fire of artillery directed against it; for then a great body of men may be thrown upon a point which is too feeble to resist it, and the line will be penetrated or turned before troops can be brought up from the remoter parts to check the assault. The duke of Wellington appears to have always deployed his columns in line previously to making an attack, and his successes prove the merit of the practice; but it requires great skill in the commander to choose the proper moment for doing it. The deployment should not take place at too great a distance from the enemy's line, since the impediments of the ground may cause that of the assailants to be broken again before it arrives at the place where the charge is to be made; neither should it be postponed till the heads of the columns are very near the enemy, since then the fire of the latter might cause such confusion among the troops as to render them incapable of executing the manœuvre.

The marches of armies are necessarily made in columns, the breadths of which are of course regulated by the nature of the roads along which they are to move. When an army divided into columns has to proceed by different routes into a new position, the number of battalions of which each column is to be composed must be so determined, that all the columns, by arriving at their places on the ground at the same time, may be enabled immediately to form the line of battle.

COLUMNA'RIA. [Madrephylliœa.]

COLUMNI'FERÆ, an old name of Malvaceous plants.

COLURES (*αἱ κόλουροι*, *colúri*). The term was originally applied to any great circles of the sphere passing through the poles, but came at last to mean only the circles which also pass through the equinoxes and the solstices, which are distinguished as the equinoctial and solstitial colures. These terms are now of very little use, as the fact of a star being upon either circle is attended with no remarkable phenomenon. Astronomers would describe a star on the equinoctial colure as having either no right ascension, or twelve hours of right ascension, according as it is on the vernal or autumnal half of the circle; and a star on the solstitial colure as having either six hours or eighteen hours of right ascension, according as it is on the summer or winter side of the heavens. If we say that the sun is on the equinoctial colure at the quarter days of March and September, and on the solstitial colure at those of June and December, we rather elucidate the term colure than derive information from it.

The solstitial colure passes through the poles of the ecliptic also, and might be called an ecliptic colure; but the other circle, which passes through the equinoxes and the poles of the ecliptic, has no distinct name, and would be best described as the circle from which celestial longitude is reckoned.

COLU'RI. [Salamis.]

COLUTE'A, a Papilionaceous genus of Exogenous plants, consisting of hardy shrubs, with pinnated leaves and inflated membranous pods, which explode when suddenly compressed, and which look like vegetable bladders, whence the common English name of bladder-senna. The species have yellow or yellow and red flowers of some beauty; and are all found either in the South of Europe, in Palestine, and in the mountains of the Himalaya.

COLVILLE, JOHN, of the family of Colville, of East Wemyss, county of Fife, was some time minister of Kilbride, and chantor of Glasgow, of which latter office the church of Kilbride was the appropriate prebend; but disliking the poverty which, on the Reformation, had become incident to the condition of a Scots clergyman, he abandoned that profession about the year 1578, and was in consequence ordered by the General Assembly 'to be taken order withal for deserting of his ministry.' (Melv. *Diary*, p. 50.) He got introduced to court, and the following year we find him attending the Privy Council as Master of Requests. (*Act Parl.* iii. 150.)

He was soon afterwards engaged in the treasonable conspiracy of the Raid of Ruthven, and was on that occasion sent by the party that had seized the king's person as ambassador to queen Elizabeth, who had favoured the enterprize. On the king recovering his liberty, Colville was seized at the instance of Arran, the king's adviser, imprisoned in Edinburgh Castle, and on the 22nd of August, 1584, forfeited in parliament (*Act. Parl.* iii. 334, seq.) His forfeiture however was in all likelihood reversed, and himself restored to royal favour, not long after; for on the 2nd of June, 1587, he was appointed by the king a lord of session in the room of his uncle, Alexander Colville, commendator of Culross, who resigned, 'because through great sickness he could not await and serve the cure of the said senatory.' (*Books of Sed.*) But on the 21st of the same month he gave up the place again in favour of his uncle, and got some appointment, as it seems, in relation to the supply granted by parliament for the king's marriage expenses, part of which was employed by him in purchasing clothes for the king, and other necessaries. (*Moyse*, p. 159.) About the same time also he sat in parliament for the burgh of Stirling. (*Act. Parl.* iii. 524.)

He was probably disappointed in his expectations at court, however, for he soon afterwards joined the turbulent earl of Bothwell in his attack upon the king in December, 1591, for which he was again forfeited in parliament. (*Act. Parl.* iii. 538; Pitc. *Crim. Tr.* i. 2707.) The next year he accompanied the same nobleman to Holyrood House in a new attack upon James. But the party being discovered and defeated, Bothwell was obliged to flee; and Colville, by betraying his associates, obtained a pardon. Bothwell was afterwards excommunicated by the church courts, and not finding himself safe in Scotland, he fled to Orkney, and thence to France, whither Colville also proceeded. The latter several times requested permission of the king to return, and for that end used various arts to ingratiate himself with his majesty. In the year 1600, he published at Edinburgh a treatise entitled 'The Palinode,' which he represented as a refutation of a former treatise of his own against James's title to the English crown, which, 'in malice, in time of his exile, he had penned;' whereas, in fact, no such treatise was ever penned by him. (Spottisw. *Hist.* 457.) All his arts to obtain his recall to his native country proving unsuccessful, he at length professed himself a Roman Catholic, and became a keen writer against the Protestant faith. In 1601 he wrote a 'Parænesis ad Ministros Scotos super sua Conversione,' which was translated and printed at Paris the following year. He wrote also 'Capita Controversa,' and 'De Causa Comitis Bothwelli,' who, like himself, had turned Roman Catholic. Charteris (*Lives of Scots Writers*) mentions another work of his, 'Oratio Funebris Exequiis Elizabethæ destinata; and the author of the 'History of Sutherland' speaks of a manuscript left by him touching the affairs of Scotland.

He died while on a pilgrimage to Rome in the year 1607.

COLY'MBIDÆ. [Divers.]

COLY'MBUS. [Divers.]

COMA, a Greek word (κῶμα) signifying profound sleep; a morbid condition of the brain, attended with loss of sensation and voluntary motion, the patient lying as if in deep sleep.

It can scarcely be considered a primary or idiopathic disease; it is rather symptomatic of that condition of the brain which, when in sufficient intensity, produces apoplexy. If it be regarded as a positive disease, it must be considered as a milder form of apoplexy. It exists in different degrees of intensity; several of which degrees, as they are attended with some variety in the symptoms, and are dependent on some modification of the pathological condition of the brain, so they have acquired distinct names. When there is a state of mental and physical torpor, indicated by an almost constant tendency to sleep, and great inaptitude for muscular exertion; when the patient is sensible only as long as he is strongly excited, and as soon as the external stimulus is withdrawn, lapses into a state of forgetfulness, the affection is called Lethargy. When no distinct consciousness returns, however the patient may be roused or stimulated, though there still remain some indication of feeling on the application of mechanical irritation, as on being pricked or pinched, the affection is called Carus. But when the insensibility is so great that the patient indicates neither sensation nor feeling, whatever mechanical stimulus be applied, this state is often called, by way of eminence, Coma. This comatose state invariably accompanies apoplexy, and, as has been stated, coma, when intense, passes into apoplexy.

The abolition of sensation and voluntary motion (animal functions), which constitutes coma, is always attended with a greater or less disturbance of the organic functions. The circulating system is disordered: the pulse at one time is slow and full, and at another quick and small. The respiration is laborious, and is commonly preternaturally slow. The power of generating animal heat is almost always diminished, the skin being cold and clammy, though there are cases in which the temperature is elevated somewhat above the natural standard. The countenance is usually pale and sunk; the pupils dilated, but in the worst cases contracted; the position of the body is supine; in the worst cases there is a constant tendency to sink down in the bed; the limbs are motionless; and the evacuations, if not wholly retained, which is usually the case, are passed without consciousness.

In coma there is an exhaustion or suppression of the sensorial power; in other words, an abolition of the cerebral functions. This state of the nervous is always attended with a morbid condition of the vascular system. There is either a congestion of the capillary blood-vessels, occasioning obstructed circulation of the blood through the brain, or there is too rapid and violent a flow of blood through the cerebral vessels; or an inflammatory condition of the blood-vessels; or an extravasation of blood, or an effusion of serum into the cerebral substance. In addition to its disordered motion, there is also sometimes a depraved quality of the blood. There is reason to believe that to some morbid change in the constitution of the blood, the coma incident to bad types and advanced states of fever is mainly owing.

The morbid condition of the brain, on which coma depends, may be induced by any of the causes which have been enumerated as constituting the predisposing and exciting causes of apoplexy. [Apoplexy.]

Coma, which may depend on directly opposite states of the nervous and sanguiferous systems, requires, in different cases, directly opposite modes of treatment. On the discrimination of the exact pathological condition with which, in any given case, coma is connected, and on the adaptation of the remedies employed to that pathological condition, life depends. If coma result from a simple depression or exhaustion of the nervous energy, and be attended with a feeble, irregular, and intermittent pulse, a cold and clammy skin, and a pallid and sunk countenance, the abstraction of the smallest quantity of blood will be certainly fatal. In this modification of the affection, not a depressing, but the very opposite, a stimulating treatment is required. The most appropriate stimulants are those denominated the diffusible, such as ammonia, camphor, &c.; but remedies of this class, whether used externally or internally, or both, must be employed with caution, and their effect watched with vigilance; for the too violent or the too long continued use of them, may actually superinduce a more dangerous form of disease, and convert simply exhaustive into congestive coma. Counter-irritants are almost always safe, and often highly useful; such as blisters to the nape of the neck, or over the scalp, or behind the ears.

When coma depends on congestion of the capillary vessels of the brain; when the pulse is oppressed, irregular, and slow; when the respiration is laborious and slow; when the countenance is tumid, and of a purple or livid colour, local depletions, as by cupping applied between the shoulders, or at the nape of the neck, or by leeches to the temples, counter-irritants, as in the preceding variety, and active purgatives, constitute the most efficient remedies.

When coma depends on the too rapid and violent flow of blood through the cerebral vessels, or on an inflammatory condition of those vessels, indicated by the full and strong pulse, and the hot skin, the same remedies must be employed, but with much greater activity. Life or death depends on the extent to which these remedies are carried, on the decision which sees how far to go, and the discernment which knows when to stop. [Apoplexy.]

COMA BERENI'CES (Constellation), the hair of Berenice, placed among the stars by the astronomer, Conon, in memory of Berenice, the wife of Ptolemy Euergetes. (B.C. 246.) The legend is, that she had dedicated this hair to Venus, in case of her husband's safe return from Asia, and that it disappeared from the temple in which it was placed, and was never seen again till found in the starry heavens, where it now is, close to the tail of the Lion, and passing the meridian about an hour before Arcturus. [Berenice.] Geminus attributes the constellation to Callimachus, who mentions it, as do Catullus and Pliny. Ptolemy does not place the stars now belonging to this constellation by themselves, but in the tail of the Lion; and Hyginus makes no separate mention of it. It was constantly mentioned by writers on the sphere, but not figured or catalogued separately, as far as we can find, till the time of Tycho Brahé.

The principal stars are as follows:—

Character.	No. in Catalogue of		Magnitude.	Character.	No. in Catalogue of		Magnitude.

The constellation Coma Berenices will be found shut up in the triangle formed by the three bright stars, Arcturus, β Leonis, and α Canum Venaticorum.

COMA'TULA (zoology), Lamarck, ALECTO, Leach, a genus of radiated animals. Linnæus appears to have confounded the form with the other star-fishes; for it is only noticed by him as a species of his genus Asterias. Neither Gmelin nor Pennant disturbed this arrangement. M. de Fréminville (*Nouv. Bull. des Sciences*,) seems to be the first who formed a genus for it, under the name of *Antedon*. Leach characterized it generically under the name of *Alecto*. Lamarck makes it the first genus of his first family (*Les Stellérides*) of his order of *Echinodermatous Radiaria*, placing it immediately before *Euryale*. Cuvier arranges the genus under his *E'chinodermes Pédicellés*; observing, that it is near to the division of the *Euryales* and *Comatulæ*, that the *Encrinites* ought to have their position. Miller is of opinion that *Comatula* presents a conformity of structure with that of the *Pentacrinite* almost perfect in every essential part, excepting that the column is either wanting or reduced to a single plate; and M. de Blainville makes it come under his first section (Free Asterencrinideans) of his third family (Asterencrinideans) of his third order (Stelleredians) of his first class (Cirrhodermarians) of his first type (Actinozoarians) of zoophytes. Mr. Thompson is of opinion that his *Pentacrinus Europæus* is the young of *Comatula*.

---

* This star has been repeated twice by Flamsteed. It is 36 Virginis (Baily.)

M. de Blainville, whose observations appear to be founded on examination of a foreign species preserved in spirit, and on dissection, thus characterizes the genus.

Body orbicular, depressed, membranous; protected above by an assemblage of calcareous pieces, of which one is medio-dorsal, with one or two rows of accessory articulated simple rays, and provided on its circumference with five great rays, deeply bifid and pinnated, commencing with three basilary pieces. *Mouth* rather anterior, isolated, membranous, at the bottom of a star formed by five bifurcated channels. A large pseudo-anal orifice at the fringed extremity of a visceral sac.

The following details of structure are given by the same author. The body of Comatula is almost entirely membranous below; above, on the contrary, it is protected by a sort of *cupule*, which is thick, and composed of calcareous pieces, articulated and held together by a very delicate and hardly distinct skin. This *cupule* is formed by a centro-dorsal part, in which two pieces placed one over the other enter. It is round the first that the auxiliary rays are articulated, and to the second the great rays are joined by means of their basilary part.

The auxiliary rays, whatever may be their number—for they may form one or two rows—are always simple; that is, they are composed of simple articulations joined end to end, of which the last is attenuated and curved into a hook (*fig.* 5). They are never pinnated, and it would appear that they are not provided with any suckers.

The great rays enter by their base into the composition of the cupule or cell in which the visceral mass is contained. Each of them is formed by a simple basilary part, and another much more extended, divided, and pinnated. The basilary part is composed of three joints, a first articulated with the centro-dorsal piece, a second intermediate, and a third terminal, with which the two principal divisions of the rays are joined, and which on that account is shaped into an angle at its summit. The joints of this basilary part not only articulate with each other, but laterally they touch the corresponding parts of the two neighbouring rays. By such a disposition, becoming more and more complex, it is that the heads of *Encrinites* and the genera allied to them are formed. With regard to the pinnated or complex part of the ray, it is at first constantly double, that is, formed of two digitations, which are themselves often subdivided in a variable manner; so that sometimes the comatula bears a resemblance to a great figure of a sun: each subdivision is composed of joints in general but little elongated, which augment but little in number in a given space in proportion as they approach towards the extremity. Their most remarkable points are, that they alternately differ a little in length, and that the longest carry, right and left, on their internal surface, compressed triangular pinnules nearly cirrhous at their extremity, and also composed of a great number of short articulations. The result is, that when the animal is dead the digitation resembles the leaves of the mimosæ, because the pinnules in repose cling one to another like the folioles of sensitive plants throughout the length of the rachis when they are closed. But the principal character which distinguishes the great rays from the accessory ones is, that through the whole length of the axis and pinnules, the buccal or labial channel, fleshy and provided with sucking cirrhi, serving the animal to seize its prey, is continued. In following out these channellings (*espèces de sillons*), the number of which is in proportion to that of the digitations of the ray, we arrive by means of a channel from each, and occupying its base, at the centre of a sort of star with thick fringed borders, and finally at the mouth which is at the bottom. The star formed by the junction of the channels of the rays is not symmetrical, that is, its branches are very unequal; some which we shall call the anterior ones being shorter than the others, or posterior ones. The result is, that the mouth is not at the centre of the star, but much nearer one side than the other: it is difficult to be seen, which is not the case with another orifice which we shall presently discuss, and which M. Lamarck seems to have taken for it. The mouth is deeply buried in the star of the channellings, is round, unarmed, and leads immediately into the stomach. What is remarkable in this last is, that its parietes are thick, and especially that it is not simple. It is in fact full of lacunæ, or rather it forms a sort of cavernous tissue, enveloped on all sides by a yellow granulated matter of some volume, which must be the liver. The result of this disposition of stomach and liver is a considerable visceral mass, which occupies the excavated part of the calcareous cupule, and which is attenuated by degrees as it retires backwards, where it terminates in a soft and obtuse point. All this mass projects in the interior of a large cavity, of which it remains to speak. This cavity entirely membranous—at least below, for above and on the sides it is doubled by the solid parts—surrounds the visceral mass, and detaches it from all the rest of the animal, except towards the mouth, where it is continued. The internal orifice M. de Blainville was unable to discover. It is perfectly smooth, but it is prolonged externally into a sort of bladder (*vessie*), the base of which is behind, and whose truncated summit is forward. This free summit passes even a little beyond the mouth as it advances below it. It is pierced by a large gaping orifice, provided with a circular row of tentaculiform papillæ. 'This,' says M. de Blainville, 'is the part which M. de Lamarck took for the mouth, and which the English authors have considered to be the vent; it is really neither the one nor the other.' He then asks whether it may not be a sort of respiratory or locomotive cavity, or the termination of the ovaries? a question which he is unable to solve, inasmuch as he could not find the organs last named in the only individual which he dissected. 'However that may be,' he adds, 'it is at least easy to perceive, from what has been said of the organization of the *Comatulæ*, that these animals differ considerably from the *Ophiuræ* and other true star-fishes; and their habits are different, so far as is known.'

'Probably free wanderers in the seas which they inhabit, it is asserted that they attach, or rather anchor themselves to rocks by means of their accessory rays, using the others, which they extend on all sides, to reach their prey and bring it to the buccal orifice. It is worthy of inquiry, whether the Comatulæ do not make use of the abdominal bladder for the purposes of locomotion, in contracting it on the water, which would penetrate it somewhat after the manner of the Sepiæ.' (*Actinologie.*)

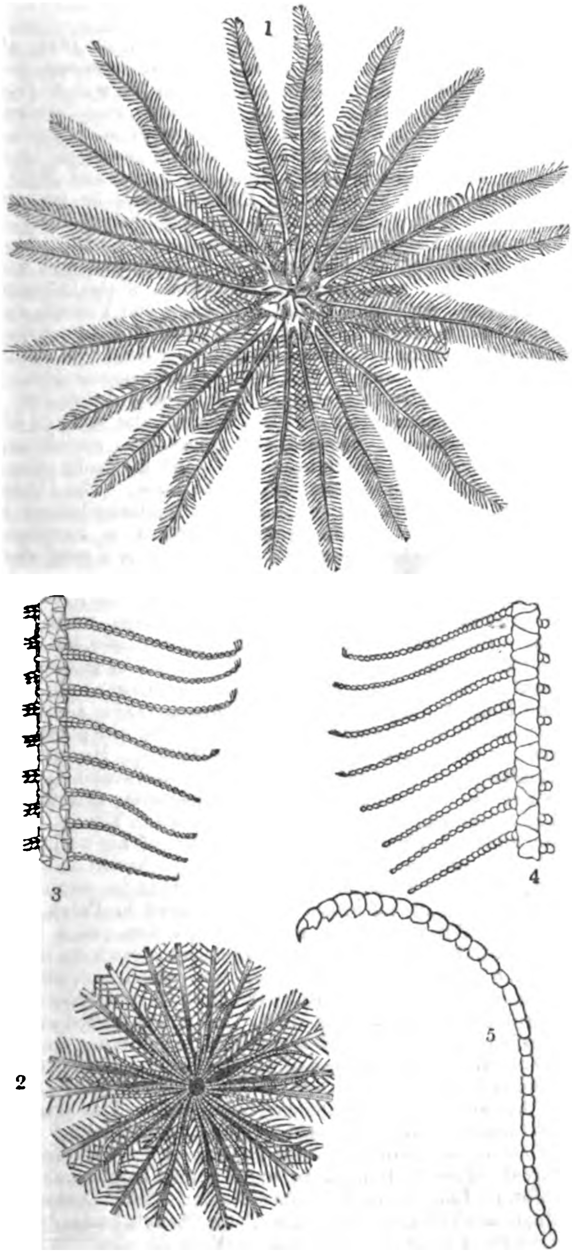
In the 'Descriptive Catalogue of the Museum of the College of Surgeons' (Physiological Series, vol. i.), there is a notice regarding *Alecto Glacialis* (No. 435, A), which imports that the alimentary canal is continued in a spiral direction from the sub-central opening at the convergence of the radiated canals to the opening at the extremity of the fleshy tube which projects forwards by the side of the mouth, forming a second distinct orifice or anus. Mr. Owen at first followed Lamarck in considering this tubular orifice as the mouth; but after dissecting a specimen carefully, and considering the analogy of *Alecto* with the other *Asteriæ*, he regarded it as the superadded orifice, and the sessile orifice at the convergence of the canals or channels as the normal orifice, and consequently the mouth. He is of opinion that this tubular orifice cannot be the opening of the oviducts, because the ovaries are situated in membranous expansions on the inside of the pinnules of the rays, as will be described in another part of the 'Physiological Catalogue.' That the tubular cavity should be a locomotive organ he considers most improbable, to use no stronger term; indeed the animal is so well provided with moveable rays, that such an adaptation would be superfluous; whether or not some respiratory actions are effected by the fleshy tube and receptacle is another question, requiring observation on the currents, &c. while the animal is living, for its solution.

Péron states that these *Radiata* suspend themselves by the small arms from fuci and polyparies, and in that position watch for their prey, which they entrap in their spreading arms.

Geographical Distribution. The form is widely distributed: it occurs in our own seas, and in the southern ocean. In the museum of the College of Surgeons are two specimens from the Society Isles, one brought up from a depth of 226 fathoms, in lat. 80° 26′ N., long. 12° 30′ E. (H.M.S. *Dorothea*, Captain Buchan, R.N.); and the same species (*Alecto glacialis*) from 250 fathoms, lat. 80° 26′ N., long. 11° 32′ E. (H.M.S. *Trent*, Lieutenant Franklin, R.N.)

The species probably are tolerably numerous. Dr. Leach records three species, two in the British Museum, Lamarck eight, and De Blainville nine.

Example. *Comatula Adeonæ*, Lamarck, who thus describes it. 'Comatula with ten pinnated, slender, penniform rays; pinnules lanceolate, complicatedly canaliculate below; twenty dorsal cirrhi. '*Locality*. The seas of New Holland, where Péron and Lesueur found it hooked on to an Adeona. It is small, delicate, with ten very slender feathery rays, and only three inches in diameter. The pinnules are lanceolated, and folded in two, as it were, below, longitudinally.' Many of the species are of comparatively large size; *Alecto horrida*, for example.



1. Comatula Adeonæ, 3-4ths of the natural size, lower side. 2. Upper side of the same. 3. Part of the under side of a ray magnified. 4. Upper side. 5. One of the dorsal rays magnified, showing the hook or anchor (De Blainville).

Zoologists generally use the term Comatula to express this form. According to the right of priority, Dr. Leach's name Alecto should be retained: Lamouroux has since used the term to designate a genus of fossil *polyparia*. [Cellariæa, p. 405.]

Fossil Comatulæ.

Goldfuss enumerates four species from Solenhofen (Oolitic group). (See Schlotheim, Petrefactenkunde, pl xxviii. fig. 1—4): and there is a very doubtful announcement by Defrance, in his tableau, of one from the chalk.

COMBAT, SINGLE. [Duel.]

COMBINATIONS AND PERMUTATIONS. By the word combination is usually meant any selection which can be made out of a number of different objects without reference to the order in which they are placed: while by a permutation is meant a combination in which different orders of position are to be considered as constituting a specific difference. Thus *a b c d*, *a c b d*, *d a c b*, are all the same combination of four out of the alphabet, but different permutations of four. The investigation of questions relating to combinations, &c., is the principal mathematical part of the theory of probabilities, and was first considered in detail, with reference to that science, by James Bernoulli and Montmort (see 'Library of Useful Knowledge,' *Probability)*: but the common rules had previously found their way into arithmetical treatises. The enormous number of different arrangements of which objects are susceptible, even when their number is not large, drew early attention to the subject. We shall give some of the most simple rules, as a help to calculation for high numbers.

I. The number of permutations having x in each, which can be made out of X quantities, is the product of x terms of the series.

$$X, X-1, \quad X-2, \quad X-3, \&c.$$

Thus out of 10 quantities, there are 10×9, or 90 permutations of two; $10 \times 9 \times 8$, or 720 permutations of three; $10 \times 9 \times 8 \times 7$, or 5040 permutations of four; and so on. Finally, the number of different arrangements which the whole ten will admit of, say the number of changes which can be rung on ten bells, is

$$10.\ 9.\ 8.\ 7.\ 6.\ 5.\ 4.\ 3.\ 2.\ 1.\ \text{ or } 3{,}628{,}800.$$

II. When the whole number of quantities, X, contains a, which are alike of one sort, b, which are alike of another sort, &c., the total number of arrangements of the whole, is not the product of X, X — 1, &c., down to 1, but that product divided by the product of 1, 2, 3. . . . up to a, then by that of 1, 2, 3, . . . up to b, &c. This result can be most easily formed by striking out common factors from the numerators and denominators.

III. In the last case, the number of permutations of x out of X being required, no simple rule can be given, but each case must be solved by itself. For instance, how many permutations of three can be formed out of

$$a \quad a \quad a \quad b \quad b \quad c.$$

(1.) All being different, 3. 2. 1. or 6. (2.) Where a is repeated twice, we have 6. (3.) Where a is repeated three times, one only. (4.) Where b is repeated twice, we have 6. In all, 19.

IV. The number of combinations of x quantities out of X, all different, is

$$\begin{array}{c}\text{prod. of } x \text{ terms of } X,\ X-1,\ X-2,\ \&c.\\ \text{divided by}\\ \text{prod. of } x \text{ terms of } 1,\ 2,\ 3,\ \&c.\end{array}$$

Thus out of 10 quantities, the number of combinations of four is 10. 9. 8. 7. divided by 1. 2. 3. 4, or 210. The best way of arriving at this result is by destroying common factors, which shows it to be 5. 3. 2. 7. Observe also that we may shorten this process, when x is greater than the half of X, by finding out, not how many selections can be taken, but how many remainders can be left. Thus the number of combinations of 25 out of 30, is the same as the number of combinations of 5, for 25 can only be taken in as many ways as 5 can be left.

V. The number of ways in which n places may be filled up with x letters, allowing any letter to be repeated in all or any of the places, is x^n, or the product of $x, x, x, \ldots.$ (n factors in all.)

VI. The total number of combinations of all sorts out of x quantities, from one at a time up to all together, both inclusive, is 2^x, or 2. 2. 2. . . . . (x factors in all) diminished by 1. Thus out of 4 quantities, or less, there are $2^4 - 1$, or 15 different selections: they are

$$abcd,\ bcd,\ acd,\ abd,\ abc,\ ab,\ ac,\ ad,\ bc,\ bd,\ cd$$
$$a,\ b,\ c,\ d.$$

Among the curiosities of this subject, it will suffice to mention the following: The number of all possible arrangements of letters, repeated or not, and capable of being pronounced or not, up to words of 24 letters, is of the following order of magnitude. Take a million of millions: repeat it a million of million times: the result is between 1391 and 1392 millions of such numbers. As an instance of the manner in which the dropping of consonants and confusion of vowels may permit possible alterations of spelling, M. de Mairan computed that the word *Hainaut* might be spelt in 2304 different ways, so as to be pronounced in the same way by as many different Frenchmen, or very nearly so.

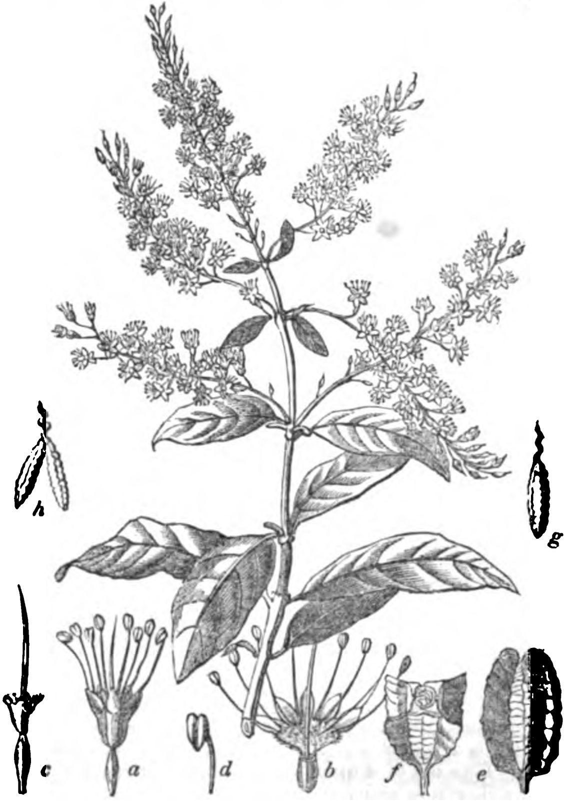
The most useful proposition in the higher part of the theory of combinations is the reduction of the formula $1.2.3\ldots.(x-1)x$ to a very close approximation, which can be easily calculated by logarithms. It affords, at the same time, a useful lesson to those who have not studied mathematics at all, or very little; we have seen ignorance comfort itself with laughter more than once at the idea of the preceding product being found by employing the proportion which the circumference of a circle bears to its diameter. But let $\pi = 3{\cdot}141593$ be this proportion; $\varepsilon = 2{\cdot}718282$, the base of Napier's logarithms· then we have

$$1.2.3\ldots\ldots(x-1)x = \sqrt{2\pi x}\left(\frac{x}{\varepsilon}\right)^{x} \text{ very nearly;}$$

which is a little too small, but the error is only about the $12x$-th part of the whole: less than 1 per cent. even when x is so low as 10. The expression can easily be calculated by logarithms Tables of the logarithms of this product will be found at the end of the Article, 'Theory of Probabilities,' in the 'Encyclopædia Metropolitana.' For an instance of the computation, see the 'Library of Useful Knowledge:' 'Examples of Arithmetic,' &c., p. 45.

COMBRAILLES, a district in France, in the former province of Auvergne; it is the north-west part of that province, on the confines of La Marche, and is traversed by the upper waters of the Cher, a tributary of the Loire. It is divided into Combrailles, properly so called, of which the capital is Evaon or Evaux, and Franc-Alleu, of which Sermur is the chief place. Combrailles is now included in the department of Creuse.

COMBRETA'CEÆ, an order of polypetalous exogens, with one-celled inferior fruit, the seeds of which are solitary or nearly so, and pendulous, the stamens definite in number, and the cotyledons convolute. They are tropical shrubs or trees, with alternate or opposite leaves destitute of stipules, and long slender stamens. The order does not contain any plants of much importance for their useful properties. Some of them are astringent and used for tanning, and the kernels of others are eatable; they are chiefly valued for their brightly coloured showy flowers, especially in the genus Combretum



[Combretum coccineum.]

a, flower; *b*, flower opened to show the insertion of the eight stamens; *c*, pistil; *d*, stamen; *e*, fruit; *f*, horizontal section of fruit; *g*, seed; *h*, embryo

COMBUSTION. [HEAT.]

COMEDY. [DRAMA.]

COME'NIUS, JOHN AMOS, was born in 1592, at Comna, in Moravia, from which place he assumed the name of Comenius. His parents were of the sect of Moravian brethren. After studying at Herborn, near Nassau, he returned to Moravia, and became pastor at Fulneck; but that town being burnt during the religious war then raging, he lost his property, including books and MSS., and took refuge at Lesna, in Poland, where he became rector of a Moravian school. He there published, in 1631, his 'Janua Linguarum,' in Bohemian and Latin. This work established his reputation as a philologist, and was translated into most European and some of the Oriental languages. An edition in Latin, English, and French, was published in London, 1639: 'The gate of Tongues unlocked and opened, or else a Seminary or Seed-plot of all Tongues and Sciences.' It is a sort of encyclopædic phrase-book, in 100 chapters, every chapter being devoted to a separate department of natural history, the arts, or the various professions, sciences, and trades, &c., introducing most of the words belonging to each, and giving by means of the context an explanation of the same. His 'Orbis sensualium pictus, hoc est, omnium fundamentalium in mundo rerum et in vita actionum pictura et nomenclatura,' Latin and German, Nürnberg, 1659, is a vocabulary of technical words, likewise arranged in chapters, but not in connected sentences, each chapter being illustrated by a woodcut representing the objects therein mentioned. These two works resemble each other in principle, but differ in the arrangement. The 'Orbis' also has been often reprinted, and translated into various languages. A Latin and English edition appeared in London, 1777. Comenius was sought after by several governments for the purpose of reforming the system of public instruction. He came to England in 1638, and afterwards went to Sweden in 1642, where he was introduced to the Chancellor Oxenstiern; but he soon after left Sweden and retired to Elbing, where he attended chiefly to the publication of his works. In 1648 he returned to Poland. On the invitation of Prince Ragotzky, he went to Transylvania, where he established a school which he afterwards transferred to Patak, near Tokay. After directing the school for four years, he returned to Lesna in 1654, but was driven away from thence by the ravages of the religious war which continued in Poland. Lesna was burnt by the Catholics, and Comenius again lost his books and MSS. He at last settled at Amsterdam, where he found a protector in Laurence de Geer, who defrayed the expense of the publication of his 'Opera didactica,' fol., 1657, in which Comenius collected several of his works already published separately. The principal of these are: 1st. 'Novissima linguarum methodus,' a sort of universal grammar, with references to the German, Greek, Hebrew, Hungarian, and Turkish languages; 2nd. 'Janusæ Linguarum novissima Clavis;' 3rd. 'Lexicon januale, seu Sylva Latinæ Linguæ;' 4th. 'Schola Ludus,' which consists of dramatic pieces composed for his pupils at Patak and Lesna, and in which men of various classes and conditions are introduced, each speaking about his own profession or trade, and using the technical words belonging to it. Comenius's didactic works might even now furnish many useful suggestions for a system of elementary popular education. He wrote numerous other works, some historical: 'Historia Ecclesiæ Sclavonicæ,' Amsterdam, 1660; 'Historia Persecutionum Ecclesiæ Bohemiæ,' called also 'Martyrologium Bohemicum,' Berlin, 1763; 'Some Controversies against the Socinians;' 'Antiquitates Moraviæ,' which is still unedited; a Map of Moravia, with names in German and Bohemian, Amsterdam, 1627; 'Prodromus Pansophiæ,' London, 1639, a sort of prospectus of a universal cyclopædia, which was the dream of his life. In his old age he listened to some fanatics and religious visionaries, who were then making a noise, and he seemed to believe in their revelations. He died at Amsterdam, November, 1671.

COMET (*κομήτης*, from *κόμη*, hair). This term, though no doubt originally derived from the tailed comet of the heavens, yet was at one time pretty generally applied to phenomena of which it may be doubted whether many were anything more than atmospheric meteors. Since the time when observation has shown comets without tails, the following must be considered as the definition of the word:—a heavenly body, of a luminous and nebulous appearance, which approaches to and recedes from the sun, after the manner of a planet in a single revolution. This includes both the comets which return, and revolve in ellipses, and those which, for any thing established to the contrary, may move in hyperbolas or parabolas.

The present is an epoch peculiarly favourable for rejecting the nebulous but *not* luminous mass of surmises, speculations, theories, and analogies, with which a succession of ages has loaded the physical constitution of comets, the question whence they come and whither they go, and every point on which curiosity could be excited. It must be fresh in memory that in the year 1832 *two* predicted comets arrived within telescopic reach, one of which crossed the place where our earth was to be a month after. The public attention was roused almost to a pitch of terror, the result of which was that much was written on the subject, and the facts which had lain unnoticed except by astronomers were drawn forth and made as common as any other fundamental points of the solar system. Still more recent is the appearance of Halley's comet, on which, for different reasons, both astronomers and the rest of the world fixed an almost exclusive attention for months together. With three comets ranking as planets both in theory and practice, we might almost as well enumerate the astrological qualities of a planet, in treating of the elements of its orbit, as reiterate the once prevailing, but now we hope almost exploded, notions about cometary bodies. Without stopping then to ask whether we are to attribute storms, fogs, rain, or the death of princes, to the appearance of a star with a tail—or whether we are to consider it as the vehicle in which departed souls, released from the functions of guardian angels, are transported to heaven;—whether, on the other hand, it is a moral agent of evil, which should be excommunicated by the church;—or whether such a phenomenon ever was the cause of a deluge,—or whether it is a method of reinforcing the light and heat of the sun,—or ,of creating satellites, or breaking up large planets into smaller ones, or changing the climates of countries, or introducing epidemic disorders—we shall proceed to treat the subject in the same manner as would be advisable in the case of the better known bodies of our system.

A fair average description of the phenomena of a visible comet is as follows:—

A faint luminous circle is discovered by aid of good telescopes; the appearance increases gradually, and after some little time a *nucleus* appears, that is, a part in the middle which is more condensed in its light than the rest, sometimes circular, sometimes oval, sometimes even radiated like a star. The appearance still goes on increasing, the nebula round the nucleus becomes less regular, and a tail begins to form, which looks as if one side of the nucleus were projected in a stream of light away from the body of the comet, which stream grows fainter as it recedes, and finally ceases without any definite boundary. This tail increases in length, so as sometimes to spread across the whole visible heaven: sometimes there are more tails than one, and sometimes the tail seems broken off in parts; it is generally turned directly away from the sun, but this rule is by no means universal. The comet approaches the sun sometimes in an undulating and irregular curve, sometimes nearly in a straight line: it generally crosses the part of the heaven in which the sun is found so near to the latter body as to be lost in its rays; but emerges again on the other side usually with increased brilliancy and length of tail. The phenomena of disappearance are then, in the inverse order, the same as those of its appearance. Frequently it is observed that the dimensions of the comet contract a little as it approaches the sun and dilate as it recedes again.

During such appearances, astronomical observation has always, for the last two centuries, confirmed the hypothesis that the irregularity in the motion of comets arises from their motion combined with that of the earth; and that their real path round the sun is either in a parabola (the infinitely elongated ellipse), or in an ellipse so elongated as to be insensibly different from a parabola within visible limits, or finally in a measurable ellipse, which being an oval curve, ensures the periodic return of the luminary. In fact, the laws under which the orbit is described are precisely the same as those of the planets to the eye of reason, though the elongation of the orbits creates very different visible phenomena. But the stages of discovery were at considerable distances from each other as to time. Aristotle and his contemporaries supposed comets to be igneous vapours formed in the atmosphere. In his 'Meteorologica,' lib. i., he mentions various hypotheses about comets, and describes several remarkable phenomena of the kind. Ptolemy does not mention the word in his Syntaxis; but in his astrological treatise he supposes them to be formed by the motion of the planets. The opinion of Seneca, that comets were a species of planets, was a bold and happy advance upon his age. Even Galileo and Francis Bacon were of the meteoric party; though Tycho Brahé had distinctly shown from observation that his comet [BRAHE, TYCHO] was above the moon in height. Both Tycho and Kepler supposed the orbits to be straight lines. Hevelius (1668) ascertained the concavity of a comet's orbit. Doerfel (1681) is believed to have been the first who laid down the parabolic hypothesis. The *Principia* of Newton confirmed the physical part of this conjecture (in 1687), and the practical part with regard to the comet of 1680. Newton distinctly calls the old planets *planets without tails*. The well-known conjecture of Halley, obtained in 1700 from his calculations of 24 comets, with his prediction, and its subsequent verification, will be treated under HALLEY'S COMET. We may here also observe, that we shall refer the second periodic comet, as to all specific information, to ENCKE'S COMET, annexing the third of the kind (COMET OF BIELA) to this article, from its having been omitted in the proper place. The steps which have been made in positive knowledge of the orbits of comets since Halley are closely connected with the planetary theory, and will be found in articles on that subject. [GRAVITATION, PLANETARY THEORY, &c.]

Resuming the general statistics of cometary orbits, we may observe that up to the year 1665 there are 415 comets recorded: that 46 had been added up to the year 1781, that 80 orbits had been *calculated* in 1792; and that in 1831, 137 orbits had been calculated. But it must be remembered that many of these are returns of the same comet; and that many of the old comets are very doubtful.

Having examined the particular evidence for eight reputed appearances of what afterwards became Halley's comet, we can only find in the case of two as much as would establish the most ordinary historical fact; and when we state that in one instance at least the original authority for the comet lived ten centuries after the appearance, we leave our readers to reduce the number 415 according to their own judgment.

The present average seems to be something more than one comet in each year; of which, however, it is not to be presumed that one in ten is visible to the naked eye.

Of the 137 comets whose orbits were known in 1831, M. Arago made an instructive and curious analysis, which we shall here give.

Number of comets which came to perihelion (nearest point to the sun) in different months.

January	14	July	10
February	10	August	8
March	8	September	15
April	10	October	11
May	9	November	18
June	11	December	13

The number in winter is 81; in summer 56. This probably arises from the facility which long nights and feeble sunlight give to the discovery. Of these comets 69 moved *direct* (in the order of the signs of the zodiac) and 68 *retrograde*.

The three following columns show, 1. the number of comets of which the orbits were inclined to the ecliptic between 0° and 10°, 10° and 20°, &c.; 2. the number in which the longitudes of the ascending nodes (points at which they rise above the ecliptic) were between 0° and 30°, &c. 3. the number in which the longitudes of the perihelion were between 0° and 30°, &c.

Inclination.	No.	Node.	No.	Perihelion.	No.
0° to 10°	9	0° to 30°	12	0° to 30°	11
10 ,, 20	13	30 ,, 60	12	30 ,, 60	13
20 ,, 30	10	60 ,, 90	20	60 ,, 90	12
30 ,, 40	17	90 ,, 120	8	90 ,, 120	20
40 ,, 50	14	120 ,, 150	12	120 ,, 150	10
50 ,, 60	23	150 ,, 180	13	150 ,, 180	8
60 ,, 70	17	180 ,, 210	14	180 ,, 210	6
70 ,, 80	19	210 ,, 240	11	210 ,, 240	13
80 ,, 90	15	240 ,, 270	10	240 ,, 270	18
		270 ,, 300	8	270 ,, 300	10
		300 ,, 330	11	300 ,, 330	10
		330 ,, 360	6	330 ,, 360	6

from which it seems that great inclinations are more probable than small ones, that the nodes of comets are pretty equally distributed in the two halves of the ecliptic, but that the perihelia seem inclined to cluster about the summer and winter solstices. Laplace, in applying the theory of probabilities to the subject of the inclinations of the ten planets, which are not altogether as great as any one of them might have been (or 90°), ascertained that it was ten million to one in favour of some specific cause for the inclinations of planets being what they are. But on applying the same analysis to a large number of comets, he was not able to detect as much as three to one for a similar supposition in the case of comets.

With regard to the magnitude of the perihelion distances, it was found that—

Nearer than Mercury	there were	30	comets
Between Mercury and Venus	,,	44	,,
,, Venus ,, Earth	,,	34	,,
,, Earth ,, Mars	,,	23	,,
,, Mars ,, Jupiter	,,	6	,,
Further than Jupiter	,,	0	,,

or the number of perihelia do not by any means increase in proportion to the spheres within which the several planets are contained. If the perihelia were distributed throughout the system as thickly as between the Sun and the orbit of Mercury, there would be three millions and a half of comets within the sphere of Uranus.

With regard to the periodic time of comets there is little to be said, owing to the small number of verified instances. Encke's comet revolves in 3¼ years, Biela's in 6¾ years, Halley's in 75½ years (roughly): these are the three verified instances. Of predictions remaining for verification we have the following (Airy, *Rep. Brit. Ass.* vol. i.):—

Year of Comet.		Supposed Period.		Authority.
1807		1543	years	Bessel.
1811	(celebrated)	3383	,,	Bessel.
——	————	2888	,,	Argelander.
1815		72–77	,,	Bessel and others.
1819	(2nd com.)	5½	,,	Encke.
1819	(4th com.)	3¼	,,	Encke.
1812		66–76	,,	Encke.
1822	(2nd com.)	1550	,,	Encke.
1822	(3rd com.)	1817	,,	Rumker.
1825	(4th com.)	556	,,	Hansen.
1825	(?)	265	,,	Mossotti?

The short comets of 1819 have not been seen again, but this is not conclusive, as they were excessively feeble, and were very near the earth when observed. It must be remembered that these determinations are not of very high probability, since a determination of the length of the major axis is very uncertain from observations made near the perihelion, and comets are visible at no other time. The time of a revolution, when ascertained by observation, settles the major axis of a comet's orbit very completely: but it is difficult to determine the major axis with sufficient correctness by any other observations.

With regard to our general knowledge of the orbits of comets, we shall only further remark that an instance which might once have led to doubts regarding the universality of the Newtonian principle, has become a striking confirmation of it. We allude to the comet of Lexell, which appeared with brilliancy in 1770, and was most unquestionably (as was found) moving in an elliptic orbit of five and a half years in period. But it has never appeared again. It was found however from theory, that a near approach to Jupiter in 1767 changed an orbit of long period, if not a parabola or hyperbola, then in course of description, into the ellipse just alluded to, and that an orbit of long period was afterwards restored by the action of the same planet; it being easily shown that it would depend on the relative positions of the comet, the sun, and Jupiter, whether the perturbations of the latter would lengthen or shorten the period. This must have appeared a pure hypothesis to all who could not verify the process; it must have seemed that the perturbations of a planet were always ready to explain the disappearance of a predicted comet. But in the meanwhile, more than half a century has gone by; no such comet has appeared again, and it has been proved by the instances of the three verified periodic comets, that the calculated perturbations will enable astronomers to predict with great exactness the actual place in which a comet is to be seen. Consequently, to the appearance of the comets which, if the Newtonian theory be correct, should appear, we may add the disappearance of those which on the same supposition should disappear. But it is hardly necessary now to insist on such a point.

We leave the certain and numerical field of observation of orbits, and proceed to what we know of the constitution of comets. The most interesting question is that of their masses—are they solid, or mere clouds of gaseous matter? Do they derive light from the sun, or are they luminous of themselves? Do they gradually waste away, or do they continue of the same magnitude and intensity of light? These are the only questions which it is worth while to state separately, being the only ones as to which good grounds for conjecture can be given. The question relative to the masses of the comets has been pretty well settled. It may be stated as a certain fact, that though several comets have been placed in situations in which a mass as heavy as a satellite of Jupiter would have produced sensible effects of perturbation, no such effects have been produced. The comet of 1770, had it been only the five-thousandth part of the earth, would have altered the length of our year more than a second of time, which must have been observed again and again before now. The same comet must have passed in 1779 between the satellites of Jupiter: had it been the fiftieth part of one of them in mass it must have affected that system sensibly. The comet of Biela came very near the earth in 1832: not the smallest effect of perturbation has been observed. But the question has been lately brought within still narrower limits. The tail of a comet, supposing it to consist of matter like the gases on our earth (on which supposition every speculation must proceed), is a continual efflux from the body. It is impossible that a permanent atmosphere could be in equilibrium under such a form. The attraction of the body of the comet itself upon such an atmosphere must be exceedingly slight. Again, it is known from the old planets that if space be filled with any fluid, such a fluid must be excessively rare and elastic, or it would show some effect in gradually causing the planets to approach the sun, and shortening their period of rotation. No such acceleration has been observed: not that small accelerations cannot be detected, for that of the moon [LUNAR THEORY] depending on other causes, has been detected, though only amounting to a minute of space in six centuries. Nevertheless, just in the same way as the fall of a feather shows our atmosphere, though that of a bit of lead does not, it may happen that a fluid pervading all space, and so rare as not to affect the planets sensibly for many thousands of years, may soon show itself on such a mass as that of a comet. According to the observations of Encke, the comet which bears his name is gradually shortening its period, at the rate of something less than one day out of 2500, being precisely the sort of effect, and up to this time the only known sort of effect, which could result from a resisting medium. A translation of the memoir of Encke on this subject was published by Professor Airy in 1832, and both the author and translator declare themselves perfectly convinced that the resisting medium is established: M. Arago seems to be of the same opinion, as does M. Poisson. We cannot go such a length; for though we should not be willing to assert a positive conclusion against such authorities, we are obliged to suspend our opinion, either till new observations shall have confirmed the fact, or until some decisive proof shall be given, that the probable errors of terms rejected in the approximation to the perturbations are not sufficient to explain the phenomenon. But in the mean time we rest perfectly satisfied that the conclusion is one of considerable probability; and feel inclined to expect that when the comets of Biela and Halley shall be as well known as that of Encke, they will confirm the result.

It is most probable that a comet is altogether gaseous, without any solid matter whatever. Stars have been repeatedly seen through the thickest parts. Sir J. Herschel, for instance, in 1832, saw a group of stars of the sixteenth magnitude almost through the centre of Biela's comet. We shall on this subject content ourselves with citing some authorities.

M. Arago.—'I think we should conclude, 1. that there are comets without nuclei; 2. comets of which the nucleus is *perhaps* transparent; 3. comets more brilliant than the planets, of which the nucleus is *probably* solid and opaque.'

Sir J. Herschel.—'Whenever powerful telescopes have been turned on these bodies, they have not failed to dispel the illusion which attributes solidity to that more condensed part of the head, which appears to the naked eye as a nucleus; though it is true that in some a very minute stellar point *has* been seen, indicating the existence of a solid body.'

Mr. Airy.—'On the physical constitution of comets we have learnt nothing, except that they appear to be wholly gaseous.'

We cannot help being convinced that every probability leans towards the truth of the gaseous hypothesis. If this be true, we might as well attempt to ascertain how far a cloud which is driven against a mountain will tend to break off the top, as speculate upon any mechanical danger to the earth from contact with a comet. The effect of such a circumstance would be the mixture of its gaseous material with the atmosphere, a permanent rise (probably) in the mean height of the barometer (though there is no evidence to make it highly probable that all the comets put together would have mass enough to produce a sensible effect of this kind), and, if the gaseous matter should condense sufficiently to descend to the lower regions of our atmosphere, some effect upon animal and vegetable existence, as likely good as bad. For anything rendering the contrary highly probable, the earth may have been many times in the tail (or, as we might say, in the draft) of a comet.

That comets receive their light from the sun is made evident by their alterations of brilliancy. If they shone by their own light, the size would vary with the distance, but not the intrinsic brilliancy. [Light, Optics.] But nothing like phases have been observed, except in a very few instances, which are satisfactorily shown to be either doubtful as to the fact, or not such phases as should have been, the position of the sun and earth being considered. This absence of phase is in favour of the supposition of an irregular gaseous mass.

If we take all the recorded accounts, we should certainly be inclined to imagine that the whole system of comets is diminishing in brilliancy and magnitude. But these accounts were written under the bias of terror, and must be considered as most probably exaggerated. It is impossible to see how the waste which arises from the tail can go on without such diminution. The only positive fact however is this, that the comet of Halley, which in 1682 was as round and clear as Jupiter, was not visible to the naked eye in 1759, and in 1836 exhibited a medium brightness, being then in a much more favourable position. The question as to waste is therefore mixed up with others, from which it cannot at present be separated.

The nuclei of comets (so far as observed) have varied from 30 to 3000 miles; the lengths of their tails from nothing up to more than a hundred millions of miles.

The following are references to works which are easily obtained: for those of a more mathematical character, the reader may consult Lalande, *Bibl. Astron.*, and Mr. Airy's *Report Brit. Ass.*, vol. i.; Sir J. Herschel's *Astronomy*, in the Cabinet Cyclopædia; Arago, *des Comètes en général*, troisième édition, Paris, 1834; Pontécoulant, *Notice sur la Comète de Halley*, Paris, 1835; *Companion to the Almanac for* 1833 *and* 1835; *List of Comets*, by Mr. Hussey, *Philosoph. Mag.*, vol. ii.

COMET OF BIELA. In 1805 Gauss found that one of the comets of that year appeared to have a short period of about 1731 days. No prediction was attempted, nor, as it turned out, could have been made successfully. In 1826, February 27-28, M. Biela, an officer residing then at Prague, found a comet which, it seems, 'he had partly expected, (*Rep. Brit. Ass.* v. i. p. 163); but whether on account of Gauss's determination, we are not informed. It was soon found, however, that this was a repetition of the comet of 1805, and that it had a period of about six years and three quarters, or about 2460 days. Its return was predicted for 1832, and it appeared that the orbit crossed that of the earth about a month before the arrival of the latter at the point of intersection. This annunciation excited much curiosity, and in many quarters considerable excitement, if not positive alarm. We need hardly add that such a feeling was only created among those whose means of information were small: for in truth, the comet in 1836 was always more than fifty millions of miles from the earth, whereas in 1805 it had been within five millions. To this apparition of Biela's comet, we owe a very general desire to obtain information on the subject, and among the fruits of this is the excellent treatise of M. Arago, alluded to in the preceding article.

The comet appeared in September, 1832, according to prediction, and in the part of the heavens assigned to it. Sir J. Herschel describes it as a nebula of 2½′ or 3′ in diameter, of the order of W. Herschel's 'first class.' It had neither tail nor decided nucleus, but only a slight increase of density towards the centre. Very small stars were seen through it. [Comet.]

This body is now a recognized body of the solar system, its next appearance being in 1839. The following, being the elements of the orbit for 1832, is given in Schumacher's *Astronomische Nachrichten*, No. 103. To each element is annexed the effect which could be produced by the discovery of an error in the major semiaxis of the ellipse, amounting to $\Delta a \div 1000$. The perihelion passage is *mean time at Paris.*

Perihelion passage	1832 Nov. 26^d $123066 - \cdot 0009567\ \Delta a$
Inclination . . .	$13^\circ\ 13'\ 30''\cdot 33 + 1''\cdot 546\ \Delta a$
Long. Asc. Node . .	$248\ \ 15\ \ 11\ \cdot 14 + 6''\cdot 749\ \Delta a$
Dist. of perih. from asc. node on the orbit .	$221\ \ 45\ \ 3\ \cdot 96 - 4''\cdot 186\ \Delta a$
Perih. distance, Earth's distance being 1 .	$0\cdot 8790808 + \cdot 000008541\ \Delta a$
Semi-major axis . .	$3\cdot 53683 + \cdot 001\ \Delta a$

COMET OF ENCKE. [Encke's Comet.]

COMET OF HALLEY. [Halley's Comet.]

COMINES, PHILIPPE DE, Lord of Argenton, was born at the château of Comines, near Menin in Flanders, about 1445. His father was in the service of Philip the Good, Duke of Burgundy, who was also sovereign of Flanders, and Philip himself was early introduced into the court of Charles le Téméraire, Philip's son, whose councillor and favourite he became for a time. When Charles made Louis XI. prisoner at Péronne in 1468, Comines exerted all his influence to calm his master's violent temper; he acted the part of a conciliator between the two princes, and succeeded in bringing about a treaty of peace between them. This timely service was not forgotten by Louis. In 1472 Comines all at once left the service of the Duke of Burgundy, and passed into that of Louis XI., who received him most graciously, and made him his chamberlain and seneschal of Poitou. The reasons for this step on the part of Comines have remained a secret; probably he was tired of Charles's violent temper, and foresaw his impending ruin. Comines married Hélène, of the family of the Counts of Monsoreau in Anjou, who brought him as her marriage portion the fiefs of Argenton, Coppoux, Brisson, and others. Comines was employed by Louis XI. in several diplomatic missions to Savoy and other places. After the death of Louis, Comines having joined the party of the Duke of Orleans (afterwards Louis XII.), who aspired to be regent during the minority of Charles VIII., was arrested in 1486 on a charge of treason, and shut up for several months in an iron cage at Loches, and afterwards transferred to Paris. He was at last tried and condemned to banishment, and his property was confiscated, but the sentence was not executed, and the fame of his abilities induced Charles VIII. to employ him in several important negotiations. He accompanied Charles in his Italian campaign, of which he gives a good account in his memoirs. Previous to the return of the king through North Italy, in the midst of the hostile armies of the Italian princes, Comines was sent to Venice to endeavour to detach that state from the league, but he did not succeed. The battle of Fornovo, July, 1495, secured the retreat of the French across the Alps. After his return from Italy, Comines retired to his estates, where he began to write his memoirs. When Louis XII. succeeded to the crown in 1498, Comines repaired to court to pay homage to the new sovereign, for whom he had at one time suffered severe imprisonment and risked his life, but Louis does not seem to have noticed him by any marks of favour. Comines returned into the country, and he died at Argenton in Poitou, October, 1509, at the age of sixty-four. His body was transferred to Paris, and buried in the Church des Grands Augustins, where Comines had built himself a chapel. His monument has been transferred to the Musée des Monumens Français. He left one daughter, who married a Count of Penthièvre.

The memoirs of Comines contain the history of his own times, from the year 1464 to the death of Charles VIII. in 1498. He gives a faithful picture of that singular character Louis XI., whom he greatly extols for his political art. He is also a great admirer of the Venetian government. He was a cool and sagacious observer, and seems to have fully understood the crooked policy of those times. The great value of Comines' Memoirs consists in his frankness and sincerity. He is a matter-of-fact historian; like his contemporary Machiavelli, he paints men and politics such as he found them to be, with all their selfishness, craft, and evil doings, which he relates with great imperturbability. Those historians are the mirror of their age, and what that age was may be conceived by reflecting that Louis XI., Ferdinand of Aragon, the Borgias, Ludovico il Moro, and others of the same stamp, were the contemporaries of Comines. The Memoirs of Comines have been often reprinted, and translated into various languages. The edition by Godefroy and Lenglet du Fresnoy, London, 1747, consists of 4 vols., 4to., of which however the first volume only is occupied by the Memoirs, the other three being filled with numerous historical documents and additions.

COMI'TIA. Comitium originally signified a place of meeting, as the name imports. Plutarch (*Rom.* xix.) says that the plain where the Romans met the Sabines, in order to agree on the terms of a treaty, was called 'comitium.' The plural 'comitia' denotes general assemblies of the Roman people, convened by the constitutional authority of some magistrate, in order to enact or repeal anything by their suffrages. The comitia were also named 'calata,' from *calare*, to call or convene.

There were three kinds of Roman comitia.

1. *Curiata*, so called because the people met and voted in curiæ. Romulus, it is said, divided the whole Roman people into three tribes, and each tribe into ten curiæ, which were subdivided into decuriæ. The word curiæ is derived from curare, to take care of or superintend civil and religious affairs. Each curia formed a separate community for the celebration of sacred rites, for which purpose a particular priest, called curio, was attached to each curia, and a decurio to each decuria. But all the curiæ were under the superintendence of a curio maximus. A separate place, which was also called curia, was assigned to each curia for performing their sacred rites. The members of a curia were called curiales.

There is some obscurity and doubt about the antient constitution of the curiæ and comitia curiata. However, it seems certain, that the curiæ had the superintendence of sacred matters, that all the public power was united and centralized in the comitia curiata, and that the patrician order must have possessed a great preponderance in them. (See Niebuhr's *Rome*, vol. i., *on the Curies.*) In these comitia laws were made or repealed, capital crimes judged, and the king as well as the other chief magistrates of the state elected. The place of meeting (comitium) was in the forum, and in its northern corner were the rostra. There was no fixed time for the meeting of the curiæ, but they met as business required.

Servius Tullius having instituted the comitia centuriata, and the plebeians becoming powerful through the comitia tributa, the comitia curiata gradually lost almost all political power. However they still passed enactments under the title of leges curiatæ, which, before the institution of the comitia centuriata, denoted every law made by the comitia curiata; but afterwards that term was limited to express a few political rights, still reserved to the latter comitia, particularly that of granting military power (*imperium*) to those magistrates who were elected in the comitia centuriata, which could only confer civil power (*potestas*). Finally, the power of the comitia curiata was reduced to a mere formality, and represented, in Cicero's time, by thirty lictors. Still these comitia retained the privilege of adrogatio, a species of adoption. Though their political power was lost, the curiæ retained their religious functions till the last times of the republic, and always elected the curio maximus and the flamens. Their number was never augmented, as was the case with the tribes.

2. *Centuriata*. Servius Tullius, according to tradition, in order to diminish the power of the patricians, and to elevate the plebeians without giving them any power, made a new division of the Roman people into six classes, which were subdivided into centuries. There has been much dispute about this division and the number of the centuries; and the controversy scarcely admits of decision, as the antient writers (Livius, i. 43, Dionys. Halicarn., *Antiq. Rom.*, i. 19-22, and Cicero, *de Republica*, ii. 22) are of different opinions. But the nature of the institution is not so doubtful. According to the more probable opinion, the 6 classes contained 193 centuries. The first class consisted of 18 centuries of knights and 80 centuries of those (*ditissimi*) whose fortune amounted to at least 100,000 asses; the second class (*ditiores*) contained 22 centuries, and consisted of those who possessed at least 75,000 asses; the third (*divites*) 20 centuries, and consisted of those who had a property of 50,000 asses at least; the fourth class (*mediocres*) 22 centuries, of those who possessed 25,000 asses at least; the fifth class (*modici*) 30 centuries, of those who possessed 12,500 asses; the sixth class contained but one century of capite censi, *i.e.* persons counted by head and not by estates: they were also called proletarii, or ærarii.

According to this division the Roman people met in the comitia centuriata, in order to vote in centuries on public matters; that is, a decree of the assembly was made by counting the votes of the centuries. As the first class alone contained more centuries than all the other classes together, it may be said that, as Romulus had created an aristocracy of birth by his division of curiæ, so Servius Tullius created an aristocracy of fortune by his new division. In order to prevent that disadvantage, when the plebeians had obtained more power, the century, which was to give its suffrages first, was appointed by lot. The century upon which the lot fell was called prærogativa. The other centuries voted according to the order of their classes, and were called jure vocatæ. The decision by lot being regarded as a divine omen, the centuriæ jure vocatæ commonly followed the vote of the centuria prærogativa; and thus the power of the first class was balanced in some measure. A contest however sometimes arose whether a matter was to be decided in the comitia centuriata or tributa.

Every Roman citizen (in the best sense of the word, *civis optimo jure*) had the right of giving his suffrage in the centuries. The magistrates who were competent to call these comitia were the consul, the prætor in the absence of the consul, and the dictator. The magistrate who presided sat on the sella curulis. On holydays (*feriæ*) comitia were not lawful; the days on which they could be held were called dies comitiales. The place of meeting was the Campus Martius. Before the business began the auspices were taken, and if they were not favourable the meeting was deferred to another day; but if no obstacle appeared, the business was opened by reading either the names of the candidates, or the proposition of a law (*rogatio*). Originally they gave their suffrages aloud (*vivâ voce*), but afterwards by tablets, or ballot; which mode of voting was established by the leges tabellariæ, in order to secure the freedom of election. It was not till after a long contest, commenced by the tribune Gabinius, B.C. 140, that the plebeians obtained the protection of the ballot.

As the comitia curiata originally possessed the sovereign power, so, after the time of Servius Tullius, it came into the hands of the comitia centuriata.

In the first place all legislation belonged to these comitia, and the enactments made by them only were called leges (laws), being obligatory upon all the Romans. A *lex* differed both from a decree of the senate (*senatus-consultum*), and from an enactment of the comitia tributa (*plebiscitum*), which only bound the respective estates of the patricians and the plebs. If a law was to be proposed to the comitia centuriata, it was to be promulgated (*promulgata*), that is, notice of it was to be given on three market-days before the day of assembly. The proposed law being accepted by the people, which they expressed by the term 'perferre,' was, after being confirmed by oath of the people, engraved on a public tablet and deposited in the ærarium.

Henceforward all magistrates, both ordinary and extraordinary, were elected at these comitia, as consuls, prætors, censors, decemvirs, and military tribunes. Those who sought for office appeared in a white toga (*toga candida*, and hence they were called *candidati*) before the people on three previous market-days. The candidate who was elected was proclaimed by the præco, or crier; and if this formality was not observed the election was null. Until the magistrate elected entered upon his office he was called 'designatus.'

The comitia centuriata were also the court of the people (*judicium populi*), for judging public crimes (*crimina publica*) of a grave kind, which were immediately directed against the state or people; as for example, attempts upon the freedom of the people, attempts of individuals to seize on the sovereign power, insult to or the murder of a tribune. Such a crime, which was called crimen perduellionis, was different from the crimen majestatis. (Heinecc., *Antiq.*, iv. 18, 46 and 47.)

3. The *Comitia tributa* were the comitia wherein the Roman people met and voted according to tribes. The plebeians having acquired considerable power in the state, these comitia were established, B.C. 491. Neither birth nor fortune gave advantage in these comitia, as was the case in the other comitia. Every Roman citizen who was classed or registered in a tribe was permitted to vote in these comitia. The place of meeting was not fixed, but the ordinary meeting-place was the Campus Martius; sometimes also the forum or capitol, or Circus Flamininus. The same minute formalities with respect to the auspices were not necessary as at the comitia centuriata. The assemblies were called by a tribune, who also presided, if tribunes or ædiles were to be elected; but at elections of other magistrates, or if laws were to be made, consuls and prætors also might preside.

Soon after these comitia were established, all inferior magistrates, ordinary and extraordinary, were elected in them, as tribunes, ædiles, quæstors, proconsuls, and proprætors; the election of the pontifex maximus, and of various other religious functionaries, was made in these comitia. They also sat in judgment in certain inferior cases; but for capital punishments the comitia centuriata only had competent authority, and the trial of Coriolanus, as the story has come down to us, must be regarded as an anomaly and an illegal act.

It has been already mentioned that enactments made by the comitia tributa were called plebiscita, and at first bound only the plebeians. But as the power of the plebeians became enlarged by degrees, the plebiscita, after many contests between the plebeians and patricians, were made equal in effect to the leges, by the lex Hortensia, B.C. 288. (Gaius, i. 1.) From this time these comitia possessed the complete legislative power, thoroughly independent of the senate. Accordingly enactments for making war or peace, or granting a triumph, were frequently passed against the will of the senate.

In the later times of the republic, the management of the comitia became an important object both for ambitious aspirants to power, and for those who professed to maintain the rights of the people. Cæsar, after being made perpetual dictator, virtually concluded their authority by himself appointing consuls, and naming half of the other magistrates. Finally, the elections of the comitia became a mere formality.

(Sigonius *de Antiq. Jur. Civ. Rom.* i. 17.; Nic. Gruchii, lib. iii. *de Comit. Rom., in Thes. Antiq. Rom.*, ed. Græevius, t. i. p. 531, seq.)

COMMA, in music (*κόμμα*), is the difference between two sounds whose ratio is 81 : 80; or, the difference between the major tone, C D ($\frac{8}{9}$) and the minor tone, D E ($\frac{9}{10}$). Practically considered, the comma is the ninth part of a major tone. Ptolemy thought so small an interval inappreciable: Salinas asserts the contrary. Maxwell *(Essay on Tune)* agrees with the latter, and gives the following rule for tuning the comma. Obtain G, stopped as the octave to the open fourth string (on the violin), and the difference between that note and the same taken as the greater sixth below the first open string, must be a comma. We refer those who wish to go deeper into this matter to Smith's *Harmonics*. But the clearest and fullest information on the subject is to be obtained from the *Théorie Acoustico-Musicale* of M. Suremain-Missery.

COMMAGE'NE, a small district on the west bank of the Euphrates, between the river and the range of Taurus; it is included by Strabo (Casaub. 749) in the general term Syria. The chief town was Samosata, a fortified place, which contained a royal residence; it was the birthplace of Lucian. The Zeugma, or one of the great passes of the Euphrates, was in Commagene; and on the opposite bank, in Mesopotamia, was the town of Seleuceia, in which Cleopatra, who had the name of Selene or Moon, was besieged by Tigranes, and being taken prisoner, was put to death. When Pompey the Great conquered Syria, he left the little principality of Commagene to Antiochus XIII., the son of Antiochus Eusebes, who died B.C. 58. Antiochus XIV., probably his son, was king of Commagene B.C. 36, at the time of the expedition of Ventidius, the legate of M. Antony, against the Parthians under Pacorus.

COMMANDERY, a species of benefice attached to certain foreign military Orders, usually conferred on knights who had done them some especial service. According to Furetière, these Commanderies were of different kinds and degrees, as the statutes of the different orders directed. The name of Commandery in the order of St. Louis was given to the pension which the king of France formerly assigned to twenty-four commanders of that order, of whom eight received 4000, and sixteen 3000 livres each. The Order of Malta had commanderies of justice, which a knight obtained from long standing; and others of favour, of which the grand master had the power of disposal.

In England, Commanderies were the same amongst the Knights Hospitalars as preceptories had been among the Knights Templars, viz., societies of those knights placed upon some of their estates in the country under the government of a commander, who were allowed proper maintenance out of the revenues under their care, and accounted for the remainder to the grand prior at London. At the dissolution of religious houses, in the time of Henry VIII., there were more than fifty of these commanderies in England, subordinate to the great priory of St. John of Jerusalem. A few of these held productive estates, and had even the appearance of being separate corporations, so much so as to have a common seal; but the greater part were little more than farms or granges. The Templars' term of preceptory was as frequently used to designate these establishments as the term commandery. (Furetière, *Dictionnaire Universel;* Tanner, *Notitia Monastica*, edit. 1787, pref. p. xvii.; Dugdale's *Monasticon Anglicanum*, last edit., vol. vi., pp. 786, 800.)

COMMANDINE, FREDERIC, born in 1509, at Urbino, of a good family, was at first in the service of Clement VII., after whose death he studied medicine at Padua. Unsatisfied with the state of this science, he applied himself to mathematics, and finally settled at Verona as the instructor of the Duke of Urbino and his son. He died there in September, 1575.

This is all that is generally stated as known of Commandine (though there is a life of him by Baldi, which we have never seen), except the evidence which his writings afford that he is to be placed at the head of all the commentators on the mathematics of the Greeks, whether as respects the care which he took to select and print valuable remains, (several of which would probably have been lost but for him) or the knowledge which he displayed in the treatment of difficult and corrupt texts. The list of works which we have collected is as follows. The dates stand at the beginning, and separate the titles.

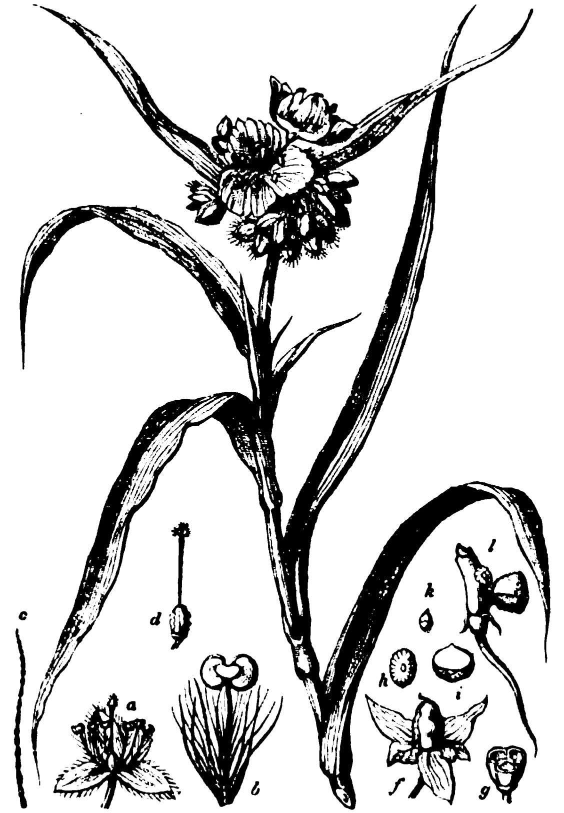
1558, Venice: the Psammites and Statical Treatise of Archimedes, in Latin, with notes (from a bad text). 1558, Venice: Ptolemy's Planisphere, with commentary, in Latin: in the same book is Jordanus, also with a commentary. 1562, Rome: the Analemma of Ptolemy, with commentary. The original is lost, but a mutilated Latin version was found by Commandine. With this came his own work on Horology, printed at Venice. 1565, Bologna; and Pesaro, 1572: Archimedes on Floating Bodies, with commentary, Latin. 1566, Bologna (and several other editions): Latin version of the four books (then known) of Apollonius, with the lemmas of Pappus, the commentary of Eutocius, and the book of Serenus on the Section of Cones and Cylinders. 1570, Pesaro: the book of Mohammed of Bagdad, on the division of surfaces, which John Dee, who found it, attributed to Euclid, and gave to Commandine. A translation into English, with Commandine's preface, is appended to the second edition of Dee's Euclid, 1660. 1572, Pesaro: Euclid in Latin, fifteen books with scholia, in folio. An Italian version of the books most commonly read, under Commandine's inspection, appeared at Urbino in 1575. 1572, Pesaro: Latin edition of Aristarchus, with notes. [ARISTARCHUS.] 1575, Urbino; and Amsterdam, 1680: the Pneumatics of Hero, with Latin version and notes. 1588, Pesaro; again in 1602; and

Venice, 1589; lastly, at Bologna, 1660, edited by Manolessius: the mathematical collections of Pappus, books 3-8 inclusive, being all which remain, folio. It is sometimes stated that the edition of Pappus appeared in 1558, which is not correct, as Commandine died before the publication, which was superintended by his son-in-law, Valerio Spaccioli, as explained in the preface.

COMMELIN, JEROME, born at Douai, in France, in the sixteenth century, embraced the reformed religion and retired to Geneva, where he carried on the business of a printer. His abilities both as a printer and a scholar, which, in that age, were often united in the same person, attracted the attention of Frederic, Elector Palatine, who invited Commelin to Heidelberg, and made him his librarian.

At Heidelberg he published editions of several Greek and Latin authors, which were valued for their correctness; among others of Eunapius, the text of which he corrected by the MSS. in the Palatine library of Heliodorus, Apollodorus, &c., to which he added critical notes. He also published a handsome edition of 'Rerum Britannicarum Scriptores Vetustiores ac Præcipui,' fol., under the fictitious date of Lyon, 1587, dedicated to Frederic, Elector Palatine. This collection consists of Geoffrey of Monmouth, Pontius Virunnius, Gildas, Bede, Gulielmus Neobrigensis, Froissart, and Buchanan's 'De Jure Regni apud Scotos.' Commelin died in 1598. He has been praised for his accuracy and learning by Scaliger, Casaubon, and De Thou. Another of the same name, and probably of the same family, was a printer at Leyden in the seventeenth century, and published a valuable edition of Virgil, with Servius' Commentaries and numerous notes, 4to., Leyden, 1646.

COMMELINA'CEÆ, a very small order of tripetaloideous endogens, consisting of plants with sheathing leaves, white or most frequently blue flowers enclosed in a green spathe, and a single three-celled ovary terminated by a single style. They are moreover remarkable for their pulley-shaped (or *trochlear*) embryo lying in a particular cavity of the albumen. None of the species are European, nor of any known use. Many of them are common Indian weeds; others are handsome American herbaceous plants. The common Spiderwort is a good type of the order.



[Tradescantia Virginiana.]

a, calyx, stamens, and pistil; *b*, stamen magnified; *c*, jointed hair from the filaments of the stamen; *d*, pistil; *f*, fruit; *g*, horizontal section of the seed-vessel; *h*, *i*, sections of seed; *k*, embryo; *l*, seed germinating.

COMMELINUS, ISAAC, born at Amsterdam, 1598, wrote several historical works in the Dutch language, among others, 'Hollandsch Placaat Boek, or Collection of the Acts of the Government of Holland,' 2 vols. fol., Amsterdam, 1644; also a 'History of the Dutch East India Company,' 4to., 1646; the 'Lives of the Stadthouders William I and Maurice of Nassau,' fol., 1651; and the 'Life of Frederic Henry of Nassau,' which was translated into French: 'Histoire de la Vie et Actes Mémorables de Frédéric Henri de Nassau, Prince d'Orange,' fol., Amsterdam, 1656; which is an interesting historical work. He also collected the materials for a description of Amsterdam, which was published by his son, Caspar Commelyn, 1694, 2 vols. fol., according to Biog. Univ. 'Beschryvinge van Amsterdam, tot den jaare 1691,' fol., 1691, with plates; a second and enlarged edition of which appeared in 1726. It is considered a very good account of that important city.

Isaac died in 1676. His brother, James Commelyn, collected many curious and scarce historical documents concerning Holland, and wrote in French, 'L'Histoire des Troubles, Divisions, et deplorables Calamités des Guerres Civiles survenues dans les 17 Provinces depuis le Commencement du Règne de Philippe II., jusqu' à la Mort de Guillaume, Prince d'Orange,' which remains unedited, as well as his 'Actes et Priviléges des Villes de Delft et Leyden, et de leurs banlieues,' 3 vols. fol.

John Commelyn, son of Isaac, and a senator of Amsterdam, published, in 1697, a work in folio, with very fine plates, of the new plants then growing in the Medical Garden of that city. Caspar, the nephew of John, gave to the world a second volume in 1702, after which he became the author of two volumes in quarto upon similar subjects. At that time the Dutch held in their hands the commerce of the east, and the Commelyns were among the first who made known in Europe the curious plants of the Cape of Good Hope.

COMMENDAM, from 'commenda,' a term of the canon law, which, according to its original signification, was applied where the custody of a void ecclesiastical benefice was, during the avoidance, committed by the bishop or other superior to a person who was to discharge the spiritual duties attached to the benefice without meddling with the profits. The person to whose charge these duties were committed was said to hold the benefice *in commendam*. In process of time, this practice of honorary custody degenerated into an actual perception of the profits, and the device of holding livings *in commendam* was found by the ecclesiastics of the middle ages a useful method of evading the provisions of the canon law against pluralities. [BENEFICE.] By the law of England, no benefice can be held *in commendam* without a licence from the crown. The instance in which this prerogative has been most frequently exercised is where the parson of a parish has been made bishop of a see, the revenues of which were insufficient to support the dignity of the station. The only way to prevent the avoidance of a benefice by promotion to a bishopric, is to grant a licence to retain it *in commendam*. This dispensation is commonly called a *commendam retinere*. (Burn's *Eccles. Law*, tit. Commendam.) It must be obtained before consecration, in case of a person being raised to the episcopal dignity for the first time, or before confirmation, in case of a translation from one see to another. The effect of it, when so obtained, is to preserve the institution, induction, or other means by which the person obtained the benefice, in full force, notwithstanding his promotion. But if the dispensation is not obtained till after consecration or confirmation, it comes too late. There is, however, another kind of dispensation, called a *commendam capere*, which enables a bishop to take a benefice after consecration or confirmation. The consent of the patron of the benefice is essential to the validity of a commendam. Such consent, therefore, must be obtained in due form before a *commendam capere* will be granted, except where the bishop who seeks the commendam, or the king, is patron of the benefice. In the former case, the acceptance of the benefice, in the latter the grant of the commendam, is sufficient evidence of the patron's consent.

In the ordinary case where a *commendam retinere* is required on account of the incumbent being made a bishop, the king is himself patron of the benefice for that time by the promotion, and therefore no other consent than what is implied by the grant of the dispensation is necessary.

Not only dignities and benefices, but headships of colleges and hospitals, may be granted *in commendam*. Several instances of such grants are mentioned by Dr. Burn.

A licence to hold a benefice *in commendam* may be temporary or perpetual. When it is temporary, the precise time is limited in the dispensation. When perpetual, the dispensation expresses that the incumbent shall hold it so long as he shall live and continue bishop of the see to which he is about to be promoted. A temporary dispensation may be renewed or prolonged. If a bishop who holds a benefice *in commendam* is translated to another see, and so a new title accrues to the crown by a new promotion, the avoidance of the benefice may be prevented; but it must be by a new dispensation, giving him permission to hold the benefice *in commendam* with the new bishopric.

By the recent statute 6 and 7 Will. IV., c. 77, sect. 18, it is enacted, that 'no ecclesiastical dignity, office or benefice, shall be held *in commendam* by any bishop, unless he so held the same at the time of passing that act; and that every *commendam* in future granted, whether to retain or to receive, and whether temporary or perpetual, shall be absolutely void to all intents and purposes.'

COMMENSURABLE. Two magnitudes are commensurable which have a common measure. The peculiar part of this subject belongs to [INCOMMENSURABLES, THEORY OF], and [PROPORTION], which see.

COMME'RCIUM EPISTO'LICUM (commerce of letters), a name which was at one time frequently given to published collections of letters, such as were common about the end of the seventeenth century and the beginning of the eighteenth. Thus we have the Commercium Epistolicum of Wallis in the second and third volumes of his works (1693 and 1699), that of Kepler (though his name does not appear in the title-page), published in 1718, and that of John Bernoulli and Leibnitz, published in 1745.

But the name by itself is generally understood to apply to the celebrated collection published by the Royal Society in 1712, in vindication of their decision upon the dispute between Keill and Leibnitz as to the right to the invention of the Differential Calculus, or Method of Fluxions. We have not space here to enter upon the subject-matter of the quarrel itself, but only to give some account of the Commercium Epistolicum, [referring for the rest to NEWTON, LEIBNITZ, FLUXIONS (METHOD OF).]

In the year 1708, Newton and Leibnitz being then both alive, Keill, an astronomer, now better known by his concern in this matter than by his writings or discoveries, inserted in the Philosophical Transactions (No. 317) an article in which he defended Newton against the editors of the Leipsic Acts, who had spoken of Newton's Quadratura Curvarum as a secondary work in comparison of the previous writings of Leibnitz. He asserted that the method of fluxions was first invented by Newton, and that Leibnitz, changing the name and notation, had inserted it in the Leipsic Acts: his words will bear the construction that he conceived Leibnitz to be a plagiarist, but not that of his being an independent inventor. Leibnitz, on the receipt of this volume (March, 1711), complained of the accusation in a letter to Dr. Sloane (then secretary of the Royal Society); reminded him that on a similar accusation having been made a few years before by M. Fatio de Duillier, the Society and Newton himself had disapproved of it; pointed out the dishonourable stigma implied by Keill (whom he presumed innocent of all bad intention), and requested the interference of the Royal Society to induce him to disavow the intention of imputing fraud. Keill (in a letter to Dr. Sloane, May, 1711) denied that he meant to charge Leibnitz with having known the science of Newton by name and notation, but asserted that Newton had explained his Fluxions in two letters to Mr. Oldenburg (then secretary of the Royal Society), which were transmitted to Leibnitz; and that the latter either did draw, or at least could have drawn, the principles of Differentials from thence. On this subject he wrote a long detail of what he considered the proof of his assertion. Leibnitz, in another letter (December, 1711), complains that the charge was now more open than before; that he and his friends had never contested the independent invention of Newton; and that he appealed to the Royal Society and to Newton himself. The Royal Society accordingly appointed a committee, which collected and reported upon a large mass of documents, consisting mostly of letters from and to Newton, Leibnitz, Oldenburg, Wallis, Collins, &c. &c. Their report was to the effect that Leibnitz was in London at the beginning of the year 1673, from which time to September, 1676 (when he visited London before returning to Hanover), he was in correspondence with Collins and Oldenburg: that when first in London, he was in possession of a differential method, which was no other than that of Mouton: and that he never mentioned any other till he wrote a letter of June, 1677, being a year after a copy of Newton's letter to Oldenburg, of December 10, 1672, had been sent to Paris to be communicated to him, and four years after Collins began to communicate the contents of that letter. Also that by a former letter of Newton, of June, 1676, it appeared that he had been in possession of his Fluxions five years before: that Leibnitz's method is in fact the same as that of Newton, with a difference of name and notation: finally, that Newton being the first inventor, Keill, in asserting the same, had been no ways injurious to Leibnitz. This report, preceded by a large mass of letters or extracts, appeared in the year 1712, and again with a Recensio, &c. prefixed, and notes by Keill and others added, in 1725. It was translated into French, and was also published in a journal at the Hague. Leibnitz only protested in private letters against the injustice of the proceeding: he declared that he would not answer a reasoning so weak: and it appears moreover that he had on his mind an impression that the acrimony excited against him in England was political. He was in the service of the Elector of Hanover, the health of the queen was declining, and many of the men of science were Jacobites.

With regard to the Commercium Epistolicum, and the Report attached, it is obvious that the final conclusion was not to the point. The question was not whether Newton was the first inventor, but whether Leibnitz had stolen the method. The committee did not attempt to prove that Leibnitz had received the letter which was sent to Paris to be sent to Hanover; nor do they formally venture to assert their belief that Leibnitz was a plagiarist: but, with a subterfuge wholly unworthy of them, they conclude that because Leibnitz might have seen Newton's letter, &c., which they could not prove, Keill did him no injustice in asserting the priority of Newton's invention—which was not the matter of complaint. Moreover, they published much of their evidence in the form of extract, and their omissions are not always justifiable. It does not appear on the face of the report itself that Leibnitz knew of the appointment of the committee, or had any opportunity of stating any objections he might entertain to its members, or of furnishing any documents relating to the question under consideration. There runs throughout the extracts a desire of proving Leibnitz guilty of more than they meant positively to affirm. The latter acted wisely in appealing to posterity; for though party feeling long adopted the conclusions of the Report in England, it is now nearly, if not quite, the opinion of those who study the matter, that Leibnitz really was an independent inventor.

The part which Newton himself took in the matter at the time is not very well known. In the first edition of the Principia (1687), he stated (book ii., Scolium to Lemma 11) that ten years before (the scolium must probably have been written in 1686 at the very latest) he had communicated *in cipher* a single sentence to Leibnitz as a key to what he informed him was a method of drawing tangents, &c., and that Leibnitz not only wrote in reply, that he had fallen upon a similar method, but actually communicated it, and that he (Newton) found it to be the same as his own, except in notation and symbols. No doubt it was upon the strength of this scolium that Leibnitz confidently appealed to Newton himself: and we might have imagined that the question of the date of this letter would have formed a part of the inquiry. But we cannot find it alluded to: the publication of the Principia is mentioned in its proper place, without a word as to this scolium; nor can we find any allusion to it. We wish we could end here: but we are compelled to add, that this scolium was omitted by Newton in the third edition of the Principia (1725), and its place supplied by another, in which the name of Leibnitz is not mentioned, but an account of what Newton had written to Collins in 1672 begins and ends in nearly the same words. But it must be remembered that between 1687 and 1725 Newton had suffered that illness which perhaps impaired the powers of his mind, and certainly altered his disposition, perhaps even his memory: for in a letter preserved by Raphson, Feb. 26, 1715-16, he gives an account of the letter of Leibuitz differing in several particulars from the printed scolium.

The Commercium Epistolicum will be found complete in Horsley's edition of Newton, accompanied by additional letters extracted from Raphson's 'History of Fluxions,' London, 1715. The appendix contains the additional letters.

COMMERCY. [MEUSE, DEPARTMENT OF.]

COMMINATION (THE OFFICE OF), a service in the Liturgy of the Church of England. It is called 'A Commination, or denunciation of God's anger and judgments against sinners,' from the Latin word *comminatio*, a threatening or cursing. The Protestants at the Reformation introduced the reading of this comminatory service as a substitute for the antient and still continued Catholic ceremony of sprinkling the head, and making the sign of the Cross on the forehead with ashes, on the first day of Lent, hence denominated Ash Wednesday; but though it is ordered especially to be read on this day, the rubric adds, —'and at all other times as the ordinary shall appoint.' From Archbishop Grindall's Visitation Articles, published in 1576, it appears at that time to have been used on four days in the year, namely, on Ash Wednesday and on the third Sunday before Easter, Whitsuntide, and Christmas. The origin and object of the service will be best explained by the following extract from its commencement. 'In the primitive church there was a godly discipline that at the beginning of Lent such persons as stood convicted of notorious sin were put to open penance and punishment in this world, that their souls might be saved in the day of the Lord, and that others, being admonished by their example, might be the more afraid to offend. Instead whereof (until the said discipline may be restored again, which is much to be wished) it is thought good that at this time (Ash Wednesday) should be read the general sentences of God's cursing against impenitent sinners.' The form of the Commination seems to be derived from Deuteronomy xi. 26-30 and xxvii. 1-26, which was afterwards strictly obeyed, as related in Joshua viii. 33-34, in the solemn rehearsal of a series of twelve curses from Mount Ebal by the Levites, with a response to each by the people. See a sermon on the 27th ch. of Deut., entitled 'the Commination Service vindicated,' by the Rev. Benjamin Camfield, 4to., 1680.

COMMINES. [NORD, DEPARTMENT OF.]

COMMINES. [FLANDERS, WEST.]

COMMINGES, a district of Gascogne, which is described in the *Dictionnaire Universel de la France* as being bounded on the north by Armagnac, on the south by the ridges of the Pyrenees which divide France from Spain, on the east by Bas or Lower Languedoc and by the district of Couserans, and on the west by Bigorre and part of Armagnac; but the subdivisions of Gascogne are so indistinctly or so variously laid down in most maps, as to make it difficult to ascertain or describe their true boundaries.

The country was divided formerly into Haut and Bas, or Upper and Lower Comminges, the southern part, towards the Pyrenees, being the Upper.

Comminges is now chiefly included in the department of Haute Garonne; some portions are included in those of Gers, Hautes Pyrénées, and Arriège. Among the towns comprehended in this district are St. Bertrand on the Garonne, and Lombes on the Save, a feeder of the Garonne, both formerly of episcopal rank; St. Girons, on the Salat (population 3634 for the town, 4381 for the whole commune); St. Gaudens, on the Garonne, (population 6179); Muret, on the Garonne, at the junction of the Louge, (population 2330 for the town, 3787 for the whole commune); and Aspet, (population of the commune 5575).

COMMISSION, in military affairs, is the document by which an officer is authorized to perform duty for the service of the state.

Antiently, in this country, the regular mode of assembling the national army, either to resist an invading enemy, or to accompany the king on a foreign expedition, was by sending a royal command to the chief barons and the spiritual lords, that they should meet at a given time and place with their due proportion of men, horses, &c. properly equipped, according to the tenure by which they held their estates; and these *tenants in capite* appear to have appointed by their own authority all their subordinate officers. But commissions were also granted by our kings to individuals, authorizing them to raise men for particular services; thus, in 1442, Henry VI. gave one to the governor of Mantes, by which the latter was appointed to maintain 50 horsemen, 20 men-at-arms on foot, and 210 archers, for the defence of that city. According to Père Daniel, the commission was written on parchment, and, that it might not be counterfeited, the piece was divided, by cutting it irregularly, into two portions, of which, doubtless, each party retained one.

Commissions of array, as they were called, were also issued by the crown, probably from the time of Alfred, for the purpose of mustering and training the inhabitants of the counties in military discipline; and in the reign of Edward III. the parliament enacted that no person trained under these commissions should be compelled to serve out of his own county except in the event of the kingdom being invaded. Of the same nature as these commissions of array was that which, in 1572, when the country was threatened with the Spanish invasion, Queen Elizabeth issued to the justices of the peace in the different counties, authorizing them to muster and train persons to serve during the war. Those magistrates were directed to make choice of officers to command bodies of 100 men and upwards; and such officers, with the consent of the magistrates, were to appoint their own lieutenants. This privilege of granting commissions to the officers of the national militia continued to be exercised by the lords-lieutenants of counties, the king having the power of confirming or annulling the appointments; and it was made law in the reign of Charles II. It appears, however, that before the Revolution, the lieutenants and ensigns were recommended for commissions by the captains of the companies.

In the French service, between the reigns of Francis I. and Louis XIV., we find that the sovereigns reserved to themselves the nomination of the principal commanders only of the legions or regiments, and that the latter were permitted to grant commissions under their own signature and seal to the subordinate officers, who were charged with the duty of raising the troops and instructing them in the use of arms.

In the British regular army, as well as in the navy, all the commissions of officers are signed by the king. In the navy, in the regiment of artillery, and in the corps of engineers and marines, the commissions are conferred without purchase; and to a certain extent this is the case with the commissions granted to officers of the line. Those cadets who have completed a course of military education in the Royal College at Sandhurst are so appointed. In other cases, gentlemen obtain leave to enter the army by the purchase of an ensigncy, the prices of which, in the different classes of troops, are regulated by authority; and they proceed to the higher grades on paying the difference between the price of the grade which they quit and of that which they enter.

The commissioned officers of a battalion of infantry are as follow: Field-officers—colonel, lieutenant-colonel, and major. Regimental officers—captains, lieutenants, and ensigns. Staff-officers—chaplain, adjutant, quarter-master, and surgeon.

For a statement of the prices of, and the fees on, commissions, see the monthly lists.

COMMITTEE, of either house of parliament, may be either of the whole House, or of a certain number of the members selected from the rest. When the House resolves itself into a committee of the whole House, the Speaker in the Commons, or the Lord Chancellor or whoever else is the ordinary Speaker in the Lords, leaves the chair, and the Chairman of Committees, a salaried officer, being one of the members, who is appointed by the House at the commencement of every parliament, takes his place. In the Commons the mace, which usually lies on the table, is at the same time placed under it. In a committee members are not restricted to a single speech on the question under consideration, but each may speak as often as he pleases. Another distinction in the Commons is, that the committee divides by the ayes merely going to the one side of the room, and the noes to the other, instead of one of the two parties going out into the lobby, as in divisions of the House. By the standing orders or established practice of both Houses, there are certain subjects that can only be brought forward in a committee of the whole House. For instance, all measures relating to the church must be so introduced; and in the Commons all propositions for the grant of money for the public service must be first made in such a committee, called a Committee of Supply; and all propositions for raising the money so granted, by taxes or loans, or otherwise, in another committee of the whole House, called a Committee of Ways and Means. No vote of a committee is of any force until it has been reported to the House, and the report received. The Committees of Supply, and of Ways and Means, always meet for the first time immediately after the commencement of the session, and are commonly continued very nearly to its close by leave to sit again being repeatedly granted by the House. Instructions directing, or otherwise to a certain extent controlling, their proceedings, are frequently issued to committees by the House, to which of course they are bound to attend. All public bills in both Houses are also considered in committees of the whole House, after the second, and before the third reading. Private bills cannot be introduced into either House, until the petitions of the parties interested for leave to bring them in have been referred to select committees; and every such bill is again referred to another select committee after the second reading. The members of select committees are commonly appointed by the open nomination of each, that is, in effect, by the vote of the House; but those of committees for trying contested elections in the House of Commons, are appointed by secret ballot. The investigation of any subject whatever that is brought before parliament may be referred to a Select Committee, and the proceedings of such committees are usually conducted in public; but sometimes a Committee of Secrecy, which takes evidence and deliberates with closed doors, is appointed, when the public safety or other reasons are considered to make that precaution expedient. A committee is generally empowered to summon witnesses, and to call for papers; but no committee of either House can administer an oath. A witness can only be examined on oath at the bar of the House of Lords.

There are some instances in former times of all the members of both Houses meeting together, at the request of one of the Houses, and such a meeting is described as a Committee of the Lords and Commons. What is called a Joint Committee of the two Houses, composed of a certain number of members selected from each, was formerly not unusual. Such a committee very much resembled a free conference; but it was sometimes resorted to after a free conference had failed to bring the two Houses to an agreement. As in the case of a conference, the time and place of meeting of a joint committee were always appointed by the Lords; and the practice was for that House always to appoint only half the number of members appointed by the Commons, a rule which is also observed in the case of a conference. A joint committee had no power to report anything more than the evidence taken by it; but still, as a division might take place on the motion for putting any particular question to a witness, the Lords have latterly considered that they were placed in a disadvantageous position in a meeting so constituted, and on the last two or three occasions on which a joint committee has been thought of the proposition has been given up on that account. In cases in which a joint committee would formerly have been appointed, the method that has of late been taken is for separate committees to be appointed by the two Houses, with power to communicate with each other. The forms at a joint committee made none of those distinctions between the Lords and Commons, which are made by the forms observed at a conference; all the members of the committee were on a perfect equality. (Hatsell's *Precedents* (edit. of 1818), vol. iii., pp. 38-45, 84-86, 169-201, *et alibi.*)

COMMITTEE OF PUBLIC SAFETY, Comité de Salut Publique, the name given to a committee of members of the National Convention, who exercised a dictatorial power in France for about fifteen months, which is known by the name of the Reign of Terror. The National Convention having abolished the royal authority at the end of 1792, and proclaimed the republic, found themselves invested with the whole sovereign power. They delegated the executive part of it to several committees of government, and placed a committee of public safety paramount over all. This committee consisted of ten members of the Convention, appointed for three months, but re-eligible indefinitely: they were commonly called the decemvirs. Their business was to watch over the conduct of the public authorities, and to promote the cause of the revolution. By degrees their powers attained a most extensive range; all the constituted authorities and public functionaries, civil and military, were placed under their immediate inspection. This was after the successful insurrection of the 31st of May, 1793, when the Mountain or terrorist party in the Convention gained the victory, by means of the armed multitudes of Paris, over their fellow-deputies of the Gironde party, who wished to govern the republic according to legal forms, and when the leaders of the Girondins were sent to prison and to the scaffold. From that time, Robespierre and his friends monopolized all the power of the Committee of Public Safety. By a decree of the Convention, 4th of December, 1793, the committee had the right of appointing and removing all the administrative authorities, all the agents and commissioners sent to the departments and to the various armies, and the agents sent to foreign countries. They were to watch and direct public opinion, and denounce all suspected persons. By another decree, of 28th of July, 1793, the Committee was invested with the power of issuing warrants of arrest. There was, besides, another committee, called de Sureté Générale, which has been sometimes confounded with the former, but was subordinate to it, and concerned itself with the internal police and judicial affairs. 'The Committee of Public Safety,' says a witness and a member of the Convention, 'did not manifest its ambition at the outset; it was useful at first. But that prudent conduct ceased after the revolt of the 31st of May, when the Convention, its several committees, and especially that of General Security, fell under the yoke of the Committee of Public Safety, which acted the part of the Council of Ten and of the three inquisitors of the Venetian government. Its power was monstrous, because it was in a manner concealed,—because it veiled its acts amidst the multitude of other committees,—because, by renewing itself perpetually from among men of the same stamp, it took away the responsibility from its members, although its measures were ever the same. The Committee concentrated itself at last in three of its members: Robespierre, who was the real chief, though half-concealed from view, and Couthon and St. Just. There was perfect unanimity among these three down to the moment of their fall; in proportion as the Mountain itself became divided, and its chiefs perished on the scaffold, the alliance between the three became more firmly cemented. There is reason to believe that they had resolved to perpetuate their power by establishing a supreme council of three consuls, in which Robespierre would have had the perpetual presidency, with the departments of justice, exterior, and finance; Couthon that of the interior, and St. Just the war department.' *(Histoire pittoresque de la Convention Nationale*, par un Ex-Conventional, 4 vols. 8vo., Paris, 1833.) The means by which these men contrived to maintain their usurped power are shown by Mignet in his History of the French Revolution. Acting in the name of the National Convention, the Committee were in fact masters of that assembly, which it obliged to adopt its reports and resolutions; it decreed the proscription of any member who resisted its will; it had at its command the armed multitudes of Paris and the suburbs, whose passions and fears it kept constantly excited by suspicions of royalists and traitors; it was supported by the numerous clubs and revolutionary committees distributed all over the country, the poorer members of which received by a decree of the Convention, extorted from that assembly on the 31st of May by the armed mob, an allowance of forty sols a day; and it sent commissioners to the armies, who impeached every general suspected of disaffection, and easily prevailed on the deluded soldiers to give him up. 'It had at its command the law against the suspected passed by the Convention, by which it could arrest any citizen; the revolutionary tribunals which summarily sent the accused to the scaffold; and the decrees of confiscation, forced loans and requisitions, and the maximum upon provisions, by which it disposed of the property of all.' This law of the maximum fixed the highest legal price of provisions and other necessaries, both for wholesale and retail dealers, forbidding them to demand more. (*Tableau du Maximum de la République Française décreté par la Convention Nationale le 6 Ventose, An II.*) The net was so widely spread that it took in all France; and a few obscure men exercised in the name of liberty a tyranny infinitely greater than that of the most arbitrary sovereigns of the old dynasty. In the Convention, from which nominally they derived their power, they were supported by a few bold men, who frightened the rest with the pikes of the mob and with threats of the scaffold. But when these men, Tallien, Barras, and others, discovered that they themselves stood in the way of Robespierre's ambition, and were destined to the common lot of the guillotine, they at once turned upon him and his friends of the Committee, and the majority of the Convention, which had through fear acquiesced in all their measures, immediately sided with them; the National Guards, weary of useless proscriptions, stood by their representatives, and Robespierre and his few friends found themselves alone, without any military man to support them. Even in the Committee of Public Safety, Collot d'Herbois and Billaud Varennes turned against Robespierre. On the 9th Thermidor, July 28, 1794, Robespierre, Couthon, and St. Just were executed. From that time the moderate party gradually, though slowly, acquired the ascendency in the Convention.

The most conspicuous members who sat in the Committee of Public Safety, besides the three above mentioned, were Collot d' Herbois, the destroyer of Lyon, Billaud Varennes, Cambon, who had under his inspection the department of finance, Barrere, who was secretary and reporter to the Committee, and Carnot, who occupied himself entirely with the military department, though his signature was affixed to several of the more obnoxious orders and despatches sent by the Committee. Herault de Sechelles, who had at first a seat in the Committee, was sacrificed by Robespierre together with Danton, whose friend he was. The public accuser, or attorney-general, was Fouquier Tinville, a most strange and repulsive character; a political fanatic, gloomy, merciless, and disinterested, who seemed persuaded that massacre was the duty of a republican. After the fall of Robespierre, Fouquier Tinville was arrested, and tried on the charge of having sent to the scaffold multitudes of men and women of all ages without any legal forms. His trial lasted nineteen days; 400 witnesses were examined for and against him; he was convicted, sentenced, and executed in April, 1795. He died poor· his whole furniture was sold for 20*l.* sterling. At the same time, Barrere, Collot d' Herbois, and Billaud Varennes, although defended by Carnot on the plea of necessity, were sentenced to transportation to Cayenne. A reaction had now taken place in the popular opinion, which pursued the agents of the proscriptions at the bar of the Convention, when their former accomplices being obliged to give them up, endeavoured to throw the whole blame upon them.

Carrier, commissary at Nantes, who invented the Noyades, or wholesale drownings of the suspected in the Loire, and who was himself a member of the Convention, was ordered for trial. He said in his defence that he had only obeyed the orders of the Convention, in conformity with their general spirit, and that the Convention could not condemn him without condemning itself: he concluded by these remarkable words:—' If I am to be punished as guilty, every body and every thing in this hall is guilty, even down to the president's hand-bell.' He was sent however before the revolutionary tribunal, and condemned for having ordered arbitrary executions with a counter-revolutionary spirit; an absurd piece of jargon, characteristic of the times. He was beheaded 16th of December, 1794. There is a very curious memoir concerning Carrier and his trial in the ' Mémoires historiques et littéraires,' by M. de Barante.

COMMODORE (*Comendador*), in the royal navy, is the officer commanding a small number of ships of war, when detached for any particular service from the fleet. His rank is immediately below that of a rear-admiral, and he is classed with a brigadier-general in the army. His ship is distinguished by a red pendant at the mast-head. The title is sometimes given to the senior captain in a fleet of merchant ships.

In the French service, the commander of a detachment of ships is called *Chef d'Escadre*; and in the time of Louis XIII. the commander-general of the fleet was so called when he had not the rank of admiral.

CO'MMODUS, LUCIUS ÆLIUS AURELIUS, son of Marcus Aurelius and of his wife Faustina, was born A.D. 161. At the age of 16 he accompanied his father in his journey to Syria, which had been disturbed by the revolt of Avidius Cassius. On his return to Rome Commodus obtained his first consulship. He next accompanied his father in his last expedition against the Quadi and the Marcomanni, during which Aurelius died at Vindebona (Vienna), and Commodus became his successor A.D. 180. Having made peace with the northern tribes he returned to Rome, where he enjoyed a triumph. For a short time he appears to have governed with moderation, while several experienced officers, Albinus, Pescennius Niger, Severus, Pertinax, and others, made the name of Rome respected on the frontiers of the empire. Commodus, however, having dismissed the counsellors and friends of his father, gave himself up to the society of freedmen, gladiators, and loose women, with whom he spent his time in debauchery. His elder sister Lucilla conspiring against him with Pompeianus, Quadratus, and other senators, they were all seized and executed. Having put to death his own wife Crispina, Commodus took for his concubine Marcia, a mistress of Quadratus, who seems to have maintained some sort of influence over him till his death. But a succession of unworthy favourites engrossed all political power, and committed every kind of injustice and cruelty. Conspiracy after conspiracy was discovered or invented by them, and a number of the principal senators were put to death, and their property confiscated. The favourites themselves destroyed each other in succession. One of them, Perennis, was put to death with all his family, and was replaced by Cleander, a Phrygian freedman, who put up to sale all the honours and offices of the empire as well as the lives of the citizens. Meantime the legions in Britain mutinied, and Commodus sent Pertinax, who had been exiled by Perennis, to appease the mutiny. In Gaul also a soldier called Maternus collected a numerous band of deserters, but Pescennius Niger being sent against him, Maternus found means to escape with several of his followers, and came secretly to Rome with the intention of killing the emperor, but he was discovered and put to death. A dreadful pestilence afflicted Rome about the same time, which lasted three years, according to Dion. Commodus, to avoid the contagion, retired for a time to Laurentum, where he continued his usual dissolute mode of life. At last a revolt broke out at Rome against the favourite Cleander; the people repulsed the Prætorian cavalry sent against them, and Commodus, to appease the storm, ordered the favourite to be put to death. In the year 191, under the consulate of Apronianus and Bradua, the Temple of Peace, one of the most splendid buildings of Rome, took fire, and vast treasures, as well as collections of books, which were deposited in it, were consumed. The fire spread to the Temple of Vesta, from whence the Vestals ran away to the imperial palace, carrying the Palladium with them. The flames extended to the imperial palace also, and consumed part of it. In the following year Commodus was consul, for the seventh time, with Pertinax, whom he had recalled to Rome. Having had repeated information of Severus aspiring to the empire, Commodus wrote to Albinus in Britain offering him the title of Cæsar, which was refused. [CLAUDIUS ALBINUS.] At the close of his career, Commodus set no bounds to his extravagancies: he disregarded common decency, exhibited himself in the circus and the amphitheatre with the gladiators, dressed himself as Hercules, whose name he assumed, and on one occasion danced naked before the spectators. (Herodian., i. 15.) Being dissuaded by Marcia and some of his officers from degrading himself in public in the company of gladiators, it is said that he wrote down their names for execution, and that the scroll being found by Marcia led to a plot against his life. However this may be, poison was administered to him, and while suffering under its effects, a powerful athleta was sent in, who strangled him, A.D. 192, in his 32nd year and the 13th of his reign. Pertinax, who succeeded him, had his body buried privately, but it was afterwards transferred to the Mausoleum of Hadrian. (Dion, lib. 12, Lampridius, and Herodianus, i. 6—16.)

Commodus had the advantage of a good education and the example of a most virtuous father; he found the empire prosperous after a succession of wise reigns for nearly a century, with a number of able officers civil and military. He left it a prey to confusion, sedition, ill-repressed irruptions of barbarians, the army demoralized, and rival generals disputing for the supreme power. The visible and rapid decline of the Roman empire may be said to date from his reign. The plea of insanity, which is put forth for Caligula's short career of frenzy, cannot be extended to Commodus; his was decidedly a vicious and depraved disposition, which had a full opportunity of displaying itself in the possession of unlimited power.

COMMON CHORD, in music. [CHORD.]

COMMON LAW. In its most general signification the expression common law denotes the ordinary law of any country; when used in this sense it is called *common*, as prevailing generally over a whole country, in contradistinction to *particular* laws, the operation of which is confined to a limited district or to a peculiar class of inhabitants. In this manner the phrase is used in many countries which have adopted the civil law. In English jurisprudence the Common Law is that body of customs, rules, and maxims which have acquired their binding power and the force of laws in consequence of long usage, recognised by judicial decision, and not by reason of statutes now extant. The common law is therefore called, in early periods of our legal history, the 'lex et consuetudo Angliæ,' and at the present day the appellation is always used to denote the 'lex non scripta,' in opposition to the 'leges scriptæ,' or statutes. In addition to customs and usages, whose particular origin is unknown, many portions of the common law consist of statutes passed before the time of legal memory, viz., the beginning of the reign of Richard I., and which, though known historically to have been acts of parliament, have no authority as laws in that character, but derive their obligation from immemorial usage, recognised by judicial decision. The provisions of the common law are, however, quite as binding upon the subjects of England as acts of the legislature, being, as already said, impressed with the character of law by force of judicial decisions. In very early times it is probable that the system of rules which composed the common law was wholly traditional. As civilization advanced, the decisions of the king's ordinary courts of justice were carefully recorded, and became the most authoritative evidence of such customs and maxims as formed part of the common law, in precise analogy to the rule of the civil law, that what the emperor had once judicially determined was to serve as a guide in all like cases for the future. (Cod. I., tit. 14. 12.) In addition to the recorded judgments of courts, technically called precedents, the treatises of learned men, such as Bracton, Fleta, Britton, Staundforde's Pleas of the Crown, and Coke's Commentary upon Littleton, are acknowledged as depositories of the common law. Of the whole system the judges of the superior courts are the expositors; they declare the law by applying certain rules and principles to cases which come before them for judgment; but they have no power directly to add to or vary the law.

Learned writers have indulged in much speculation respecting the origin of the common law of England, though Sir Matthew Hale says it is 'as undiscoverable as the head of the Nile.' It seems however to be well ascertained that the customs which in antient times were incorporated with it, were of compound origin, and introduced at various times in conformity with the political vicissitudes of the country; some being Saxon, others Danish, and others Norman. It is also quite evident, from the adoption of the Roman terms of art and several Roman provisions, that many of the rules and maxims which the common law has adopted were derived from the civil law. Again, many parts of the common law have gradually arisen from the necessary modification of its antient doctrines and principles, in order to render them applicable to new states of society produced by enlarged commerce and advancing civilization. From this cause some branches of our system of jurisprudence have wholly sprung into existence in modern times. Thus almost the whole of the law of evidence, now perhaps the most important part of our practical jurisprudence, has appeared as part of the common law so lately as the time of the Commonwealth. But perhaps the most remarkable instance of the total change in common-law institutions with the progressive improvement of society, is the trial by jury, which may be traced through all its gradations, from a rude kind of trial, in which the jury were merely witnesses called from the neighbourhood in order that they might declare the truth to the judge, to the present artificial system, where the jury themselves decide upon the truth of facts by the testimony of witnesses examined before them. On the other hand, many rules and provisions of the common law have wholly disappeared, having either become obsolete from disuse, or been gradually abrogated by decisions of the judges as they became inapplicable to the altered state of society. So great has been the alteration of the common law which these accessions and abstractions have occasioned, that it can scarcely be termed with propriety the same body of laws that it was 600 years ago, unless it be upon the principle upon which Sir M. Hale maintains its identity, viz.: that the changes have been only partial and successive, whilst the general system has been always the same, 'as the Argonaut's ship was the same when it returned home as it was when it went out, though in that long voyage it had successive amendments, and scarce came back with any of its former materials.' (See Hale's *History of the Common Law;* Blackstone's *Commentaries*, vol. i., p. 63; and Reeve's *History of English Law*, vol. i.; Hallam's *Middle Ages*, vol. ii., *on the origin of the Common Law.*)

COMMON MEASURE, any magnitude which is contained an exact number of times in two other magnitudes. Thus in the case of numbers, 7 is a common measure of 56 and 700. The method of finding the greatest common measure is precisely the same both in the science of arithmetic and in that of concrete magnitudes. The proof may be briefly stated as follows: let A and B be two magnitudes, of which B is the less. Let A contain B m times, with a remainder R, or $A = m\,B + R$. Then it is easy to show that every magnitude which measures (or is contained exactly a number of times in) A and B both, measures $m\,B$ and $A - m\,B$ or R; and also that every magnitude which measures B and R measures $m\,B$ and $m\,B + R$ or A. That is, all measures common to dividend and divisor are common to divisor and remainder, and all measures common to divisor and remainder are common to dividend and divisor. Therefore, the greatest of the common measures of either pair is that of the other. Now carry on the division as follows until there is no remainder, which suppose to happen at the fourth step:—

$$\begin{array}{llll}
\text{Let } A = m\,B + R & R & \text{is less than} & B \\
B = n\,R + R' & R' & ,, & R \\
R = p\,R' + R'' & R'' & ,, & R' \\
R' = q\,R'' & & &
\end{array}$$

Then R'' measuring itself, and also R' or $q\,R''$, must be the greatest measure common to both, for nothing greater than itself can measure R''. But the greatest common measure of R'' and R' has been shown to be that of R' and R, which has been shown to be that of R and B, which has been shown to be that of B and A.

In the case of two numbers or fractions, a common measure must be found; for two whole numbers it must be a whole number, 1 at least, if not higher; for two fractions it must be a fraction. But in concrete magnitudes the process may continue without end, which indicates that the magnitudes are [INCOMMENSURABLES], (which see for proof.) Hence the necessity, in all correct reasoning, of treating concrete magnitudes in the manner laid down in the fifth book of 'Euclid.'

In Algebra the corresponding process does not ascertain the greatest common measure, which depends upon the specific values of the letters; but only the highest common factor, or that which has the highest dimensions. This part of algebra is frequently rendered singularly obscure by the application of the arithmetical word. Thus, though the highest algebraical factor of $a^3 - x^3$ and $a^2 - x^2$ is $a - x$; this last is not the greatest common measure in all cases, as the reader may try by supposing a and x to be 8 and 6.

COMMON PLEAS, COURT OF, a superior court of record, having jurisdiction over England and Wales in all common pleas or civil actions commenced by subject against subject. It is at present composed of five judges, one of them being chief justice and the other four *puisne* justices. All are created by the king's letters patent.

This court has become stationary at Westminster Hall for several centuries. During the existence of the Aula or Curia Regis, established by the Conqueror in the hall of his usual residence, the palace at Westminster, that single tribunal exercised supreme jurisdiction over all temporal causes, which were adjudicated by the principal officers of the royal household, often assisted by persons learned in the law, called the king's justiciars. In this state of things, the poorer class of suitors in the common civil pleas or actions between man and man, in which neither the king's revenue, nor his character of prosecutor of offences on behalf of the public were concerned, laboured under the heavy inconvenience of either attending the frequent and distant progresses of the court, or of losing their remedies altogether. This evil, as well as the jealousy entertained by the crown of the ascendancy of the chief justiciar, who presided over the whole Aula Regis, occasioned the article in Magna Charta, that common pleas should not follow the king's court, but be held in some certain place. This court thereupon became gradually detached from the Aula Regis, and assumed its present separate form. It has ever since continued its sittings daily during the four terms of each year, without removal from the palace of Westminster or its immediate vicinity, except on a few occasions, in time of plague or contagious disease.

Before the passing of the late statute of 3 & 4 Will. IV., c. 27, this court had an exclusive jurisdiction in all those actions, which, as they concerned the right of freehold or realty, were called real, including as well those on which the common assurances of fines and recoveries passed, as the others which were commenced by the king's original writ out of Chancery. On this account it was styled by Coke the 'lock and key of the common law.' Since the abolition of the great mass of real actions by the above-mentioned act, dower and quare impedit are the only forms of action in which this court has exclusive jurisdiction; for in mixed and personal actions the King's Bench and Exchequer of Pleas have long exercised concurrent power.

In the original constitution of this court, and down to the beginning of the present reign, its proceedings in actions between persons not its officers were founded on original writs issued out of the Court of Chancery, though in process of time they did not actually issue except in cases where it became necessary to perfect the record. But now by a statute (2 Will. IV., c. 39,) introduced by the late Lord Tenterden, to secure the uniformity of process in personal actions in the three superior courts of law, certain forms of process, called writs of summons and capias, are provided as the only means for commencing personal actions in any of those courts, and may be issued from any of them.

Before 1830, the appeal from the judgments of this court was by writ of error to the justices of the King's Bench, a vestige of superiority resulting to the latter as constituting the remnant of that Aula Regis from which this court as well as those of Chancery and Exchequer have been gradually carved out. But now by 11 Geo. IV. & 1 Will. IV., c. 70, the judgments of this court can only be reviewed by the judges of the King's Bench and the barons of the Exchequer forming a court of error in the Exchequer Chamber; the further appeal is by writ of error returnable in the Lords' House of Parliament.

Till recently, the only persons admitted to audience as advocates in this court during its sittings in Term were serjeants-at-law. [SERJEANT-AT-LAW.] But by a royal warrant of his present Majesty, directed to the lord chancellor, in April, 1834, the right of practising, pleading, and audience in his Court of Common Pleas during Term time, was directed to cease to be exercised exclusively by the serjeants-at-law; and other counsel are to have an equal right with them so to practise there. The same warrant conferred on the existing serjeants, not being of counsel for the king, precedence at the bar (according to their seniority among themselves) next to the then junior king's counsel not being a serjeant. Those of the serjeants who had been specially retained for the crown, and were on that account styled king's serjeants, retained their old precedence before all other advocates, except the attorney and solicitor-general for the time being.

The rank of serjeant-at-law being no longer imposed by the crown without the consent or application of the individual, it is apprehended that this most antient and honourable degree will rarely be sought for by the modern barrister, it being lower in rank than the king's serjeants and king's counsel, without conferring a right to exercise exclusive advocacy in any court. It seems however that all persons elevated to the rank of judges of any of the three superior courts must still, as heretofore, be called to the degree of the coif.

COMMON, RIGHTS OF, in law, is the right of taking a *profit* in the land of another in *common* with him, whence the name arises. Such a right enjoyed in exclusion of the owner of the land seems not to be properly common, though belonging to several persons together.

The profits which may be the subjects of common are the natural produce of land (or water, which is included in the legal signification of land); such as grass and herbage, turf, wood, and fish. The commons relating to these subjects are accordingly called common of pasture, turbary, estovers, and piscary. Other things which cannot be called products of land, but rather part of the land itself, as stones and minerals, may also be the subjects of common right. Rights of way and other accommodations in the land of another, though enjoyed in common, do not bear that name, but are called *easements*.

Of all commons, that of pasture is the most frequent. It is the right of taking grass and herbage by the mouths of grazing animals. It differs from that general property, which may exist in the *vesture* or vegetable produce of the land, without any property in the land itself, and which is a corporeal hereditament; whereas all commons are incorporeal, 'as appears,' says Blackstone, 'from their very definition, an incorporeal hereditament being a right issuing out of a thing corporate, or concerning or annexed to the same.' 2 Bl. *Com.*, chap. 3. The same remark applies to other commons, the subjects of which—as for instance woods and mines—may belong as corporeal hereditaments to one, while the land generally belongs to another.

Common of turbary is the right of taking turf for fuel; and common of estovers is the right of taking *wood* for fuel, and for the repairs of houses, fences, and implements of husbandry. These supplies of wood are called fire bote, house bote (which includes the former), plough bote, and hedge or hay bote. These estovers or botes may also be taken by every tenant for life or years from the land which he himself occupies, but they are not then the subjects of *common* rights.

Common of piscary is the right of *fishery* in rivers not navigable; the right of fishing in the sea and in navigable rivers being common to all the subjects of the realm.

The extent of rights of common depends very much upon the *title* to them. There are four titles on which such rights may be founded; common right (which seems to be nearly the same thing as the common law), prescription, custom, and grant.

The title by common right arose with the creation of manors, when land was granted out in fee to be *held* of the grantor as *lord*. As such grants were forbidden by the statute '*quia emptores*' (18 Edw. I., c. 1), it follows that all commons appendant now existing must have been created before the date of that statute. The law allowed to every such grantee, of course, and of common right, common of pasture, turbary, estovers, and piscary in the *waste* of the lord, or that part of his lands which was neither taken by him into his *demesnes* or actual occupation, nor granted out by him to others. These implied rights of common however were allowed no farther than necessity seemed to require, and rights of common thus originating are still confined nearly within their antient limits. Springing from grants of land, they were considered as inseparably *appendant* to the land, so that they could not be severed from it without extinguishment. The common of pasture was confined to the purpose of maintaining, from seed time to harvest, the cattle of the commoner which were used by him in cultivating his land, and which that land would maintain through the winter, or which were, as the law styled it, *levant* and *couchant* upon it. Horses, oxen, kine, and sheep, used either for tilling or manuring land, were the *commonable* cattle. The land to which the common was appendant must have been originally arable, though the subsequent change of arable into meadow, &c. does not extinguish the right. Common of turbary appendant was confined to the purpose of supplying fuel for the domestic use of the tenant; and so strictly must this right be still confined within its antient limits, that it must be appendant to an antient messuage, and no more turves can be taken under it than will be spent in the house. Common of estovers appendant gives, as it gave originally, only the right of taking wood for the repair of antient fences and houses. Common of piscary appendant was only for supplying the tenant's own table with fish, and it must be still limited to this purpose.

Commons claimed by prescription (which supposes a grant) may be as various as grants may be. A right of common thus founded may be either annexed to land (when it is said to be appurtenant), or altogether independent of any property in land, when it is said to be *in gross*. If common of pasture, it may be for any kind of animals, whether commonable or not, as swine and geese. The number of animals may be fixed, or absolutely unlimited, and they need not be the commoner's own.

Common appurtenant may be severed from the land to which it was originally annexed, and then it becomes common in gross

The title to common by custom is peculiar to copyholders and may also give the commoner various modifications of right.

Right of common of pasture may also be claimed because of *vicinage*, or neighbourhood. This is where two wastes belonging to different lords of manors adjoin each other, without being separated by a fence. The cattle lawfully put upon the one common may then stray, or rather are excused for straying, into the other.

The rights of the owner of the soil over which a right of common exists, are all such rights as flow from ownership, and are not inconsistent with the commoner's rights.

Rights of common are conveyed, like all other incorporeal hereditaments, by deed of grant. When they are annexed to land, they will pass with the land by any assurance adapted to transfer the latter.

Rights of common are liable to be extinguished in several ways, and often contrary to the intentions of parties. It is a rule, that if the owner of common appurtenant purchases *any part* of the land over which the right extends, the right of common is *altogether* extinguished; it is the same if he release his right over any part of the land. This unreasonable rule however does not extend to common *appendant*, though that will be extinguished if the commoner becomes the owner of *all* the land in which he has common, and partial extinguishment of the common will follow from acquisition of part of the land. The enfranchisement of a copyhold to which a right of common is annexed extinguishes the right.

The most common mode of extinguishing rights of common in modern times is by inclosure under act of parliament. (See Inclosure; also generally on this subject Woolrych, on 'Rights of Common'; Comyn's *Digest*, tit. 'Common'; and Blackstone's *Commentaries*, book ii., chap. 3.)

COMMON, TENANCY IN, is one of the modes in which property may be held by several persons together. It comes the nearest to separate ownership, from which it differs in little else than that the shares held in common are not actually divided or marked out. As to alienation, transmission by descent, and other incidents of property, the law of undivided and of divided shares is the same. From the blending, however, of the shares, there necessarily arises some peculiarity in the mode of their enjoyment. When the profits of the thing held in common are partible (as corn growing in a field), they are generally actually divided among the tenants, and then the property of each most closely resembles separate property. It frequently happens, however, that this cannot be done; in which case the thing held in common must either be used alternately by the tenants (as a horse), or they must join in using it, as tenants in common of an advowson are required by law to concur in presenting to the church.

The shares of tenants in common may be either equal or unequal, and the quantity of their interests may be either equal or unequal. All may be tenants in fee, tenants for a term, &c., or one may be tenant in fee, and another tenant for a term, &c. It is necessary, however, that the possession of all be contemporaneous: successive interests are not a tenancy in common.

A tenancy in common may be created in several ways. If a joint-tenant, or coparcener, aliences his share to a stranger, the latter is a tenant in common with the remaining joint tenant or coparcener. If the sole owner of property aliences an undivided part of it, and retains the rest, the grantor and grantee are tenants in common. As to the words which, in a transfer of property to two or more persons, create a tenancy in common, or a joint-tenancy, many nice distinctions exist in the law. At common law, a conveyance of land to two simply, and without other words, made them joint-tenants, and not tenants in common; except in a few particular cases. (Litt., 283, 284.) This rule of law was founded on the feudal policy, which favoured the mode of holding property in joint-tenancy rather than in tenancy in common, because the former afforded room for the re-union of the property by survivorship (which is the characteristic incident of joint-tenancy) in a single individual, who might more effectually perform the duties belonging to the feudal tenure than several persons among whom the same burden was divided; and it is probable therefore that in the times of feudalism the intentions of grantors were fulfilled by implying joint-tenancy rather than tenancy in common. For a long time past however the courts have endeavoured, whenever they could, to raise by construction tenancies in common rather than joint-tenancies. But a tenancy in common might always be created by express words, and no technical expressions being necessary for the purpose, the courts have been enabled to lay hold of any words in a deed or will which appeared to them sufficiently expressive of a tenancy in common, in order to establish one. The misfortune however is that they have assumed greater latitude in this respect in the construction of wills and uses and trusts, than in the construction of common-law conveyances; so that the same words, as for instance the words 'equally to be divided,' often have different effects in different instruments.

The Courts of Equity have decided that in certain cases a simple conveyance to two or more makes them in equity tenants in common, and not joint-tenants, unless there is an express declaration to the contrary. This is the rule where a mortgage is made to two or more, and when an estate purchased by two or more is conveyed to them in unequal shares. This doctrine is sometimes in practice found very inconvenient.

A tenancy in common ceases as a matter of course, when the ownership of the several shares exists in a single individual: it can also be destroyed by partition made by the tenants. Any one of the tenants may compel the others, by suit in equity, to make partition of lands or houses held in common, except when the subject is in its nature not partible, as in the case of a living animal for instance.

Notwithstanding its many inconveniences, tenancy in common often occurs, being frequently created by wills and settlements in which property is given by suitable words to classes of persons together, as to children, or to a number of individuals by name.

COMMONS are wastes and pastures which have never been exclusively appropriated by any individual, but used in common by the inhabitants of a parish or district. Where extensive common rights exist, the mode of cultivating the inclosed land is greatly affected by it. All the cattle being maintained on the commons for a great part of the year, less land is laid down to grass, and only so much is kept in meadow as will produce hay to feed the cattle in winter weather, and when the commons will not sustain them. The consequence is, that the arable land is not well cultivated, little manure is made in the yards, and the rent is paid by the stock which runs on the commons, and which increases and grows without any expense to the owner. But it is a wasteful disposition of the land. Common pastures are never improved; no one will drain or clear them of weeds, still less manure them. The stock kept upon them is not by any means so numerous as could be kept on the same surface divided and improved. Hence most of the commons and common fields in Great Britain have been divided and inclosed within the last forty years. Wherever an inclosure has taken place the public has gained, even when the individuals immediately connected with the land may have suffered some loss, by not receiving an equivalent for the profit they had from the cattle which they contrived to keep on the commons.

The soil of commons within a manor belongs to the lord: if there is no manor, it belongs to the king. The herbage belongs in general to the tenants and other inhabitants of the manor or districts, according to fixed rules. Where commons are very extensive there is sometimes no restriction on the number of cattle which may be turned out on them. This is called *common without stint.*

The usual proportion given to the lord for his right in the soil on an inclosure is one-sixteenth. The remainder is divided among those who have a right of common in proportion to the land they possess, and on which their right depends.

Common fields differ from commons, in that they are divided for the purpose of cultivation; but as soon as the crop is off the ground, the cattle of all the proprietors, or of all the parishioners, as the custom may be, have a right of pasture over the whole in common. This system is incompatible with an improved husbandry, and common fields have been very generally divided and inclosed by particular acts of parliament. A late act greatly facilitates these inclosures, and will no doubt soon convert every remaining common field into enclosed farms.

COMMONS, HOUSE OF. The object of this article is to present a distinct though compendious view of the history and actual state of the House of Commons as a part of the Imperial Parliament of Great Britain and Ireland. In tracing the history of the English borough system, we have shown the origin of this house in the union of the assembled representatives of the cities and boroughs with those of the counties. It should be borne in mind that the original basis of the representation, in the time of Edward I., was very different from what we must suppose it would have been made, had the crown and its advisers at that period contemplated in this arrangement any such thing as the composition of a legislative assembly. The very large proportion of the whole number of its members that were sent from the towns, at a period when the population and general importance of the towns, as compared with those of the counties at large, were vastly less than they are now, was manifestly a circumstance repugnant to all the political notions and tendencies of the government of that day. It will be seen, on inspecting the subjoined table, that under Edward I. the town representatives bore so large a proportion to those of the shires as 246 to 74; and under Edward III. as 282 to 74. The reason why, on the first settling of the representative system into regularity and permanency, each constituency was uniformly summoned to elect *two* members, without regard to its known or presumed proportion of wealth or populousness, seems to have been very simple and very natural. So long as the parliamentary voice of the commons was confined to matters of taxation merely, the only thing that appears to have been seriously regarded in fixing the number of delegates was the securing such a delegation from each constituency as at the smallest inconvenience and expense to the latter should have full power to treat of the pecuniary business in question; and *two*, being the smallest number compatible with the important conditions of mutual consultation and joint testimony, was fixed upon as the number that imposed the smallest burden on the constituents, and was also most convenient for avoiding a too crowded assemblage of representatives. And thus it seems to have been that the periodical and frequent shire and borough courts presenting the most natural and convenient modes and occasions of appointing the parliamentary deputies of the several communities, two representatives, and two only, were summoned indifferently from the shire as from the borough, and from the largest shire or borough as from the smallest.

When the power and authority of the commons in parliament had become so firmly consolidated under the first three Edwards as to exercise an effective control over all the great measures of government, the composition of the representative body was an object of constant attention and solicitude to the crown. As the number and names of the counties entitled to send members admitted neither of doubt nor of dispute, the right of the *boroughs* became the first object of attack from that quarter. We have shown elsewhere how the attempts of this nature, made through the arbitrary exercise of the presumed power of the sheriff to select or omit boroughs, were defeated by parliamentary enactment of the 5th of Richard II.; as, in like manner, statutes were passed in the three following reigns to restrain the corrupt and irregular proceedings of the sheriffs both in county and in borough elections.

Hitherto, however, the parliamentary determinations of the commons, as regarded the constitution of their own house, had constantly tended to maintain the political rights of their constituents against invasion on the part of the crown. But that firm and lasting establishment of their own power as a distinct legislative body, which may be dated from the great revolution that first brought the house of Lancaster to the throne, seems, by that very additional security which it gave them against royal encroachment, to have tended to embolden the house, not, as formerly, to maintain the elective franchise to the utmost with the same zeal with which they upheld their own interest and independence as a legislative chamber, but to commence a sort of reaction against the constituent bodies by narrowing the basis of the suffrage itself. The earliest of these disfranchising enactments, and one of the most remarkable, is that of the 8th Henry VI., restricting the county franchise, formerly possessed by all freeholders, to such only whose freeholds were worth clear forty shillings a year, a sum at least equal to twenty pounds of the present day. The next remarkable instance, though very different in its nature, of legislative enactment respecting the constitution of the commons' house, appears in the parliamentary incorporation of Wales and Cheshire in the reign of Henry VIII. (noticed more particularly in our account of the boroughs of England and Wales), which brought an accession of sixteen county and fifteen borough members.

The *borough* representation in general was still the great object of attention to the crown in undermining the independence of the House of Commons. Under the appropriate title we have traced at length the development of that part of its policy, as diligently pursued under the later reigns of the Tudors, and carried to the utmost limit by the Stuarts; 1st, by creating or reviving parliamentary boroughs, and at the same time remoulding their municipal constitutions according to the views of the court; 2nd, by proceeding to assimilate the municipal constitutions of the old parliamentary boroughs to those of this newly-created class. Here again we refer the reader to the subjoined list, and would particularly direct his attention to the fact, that of the 46 parliamentary boroughs first created in the reigns of Edward VI., Mary, and Elizabeth, no fewer than 27 appear in schedule (A) of the Reform Act of 1832, besides five of the same number which are in schedule (B): a very clear indication as to the description of places which were chiefly selected at that period to exercise for the first time the parliamentary franchise. In the same place we have shown that the last addition to the English representation, previous to the recent changes, was, under Charles II., the enfranchisement by statute of the county and city of Durham, and the creation by charter of the parliamentary borough of Newark. Nor must we forget to mention that James I., by virtue of his royal prerogative, had conferred the right of electing two members upon each of the two universities of Oxford and Cambridge, quite independently of the city and borough representation of those places already existing: thus introducing an anomaly, as well as novelty, into the representative system, a sort of forced alliance between learning and politics, emanating from the peculiar mental constitution and training of that prince.

Those who conducted the revolution of 1688 made much more effectual provision against the return of Roman Catholic ascendency than they did for the purification of the representative system. The Bill of Rights does, indeed, express, 'that the election of members of parliament ought to be free;' but this vague declaration seems to have amounted to nothing more than an indication of the prevailing public opinion on the subject. We find another strong proof that the public attention had now begun to be directed, not merely, as in former times, to upholding the authority of the Commons' House as constituted in parliament, but to the nature of the relations, on the one hand between the house and the constituent body of the nation, on the other between the several members and their individual constituencies, in the enacting of the statute commonly called 'the Triennial Act,' which deprived the crown of the power of continuing the same House of Commons for a longer period than three years. The Triennial Act of 6 and 7 William and Mary, c. 2, was an enactment wholly on the side of electoral freedom. The discretionary power previously exercised by the crown, not only of dissolving, but of continuing at pleasure, was highly favourable to any such view, on the part of the crown, as that of forming a tacit compact with a corrupt or servile majority of the Commons' House, and was therefore, as had been lately seen under Charles II., exceedingly convenient both to king and commons, when the latter happened to be sufficiently pliant. So strongly however was the popular opinion on this point expressed at the period in question, that it compelled the commons to persist in the measure in spite of King William's refusal of assent to the bill after its first passing the two houses, so that on the second occasion his assent was reluctantly yielded. The same activity of the public opinion of that day respecting the composition of the commons, produced the several Acts of that reign which disqualify various classes of placemen for seats in the house.

In this place we must notice the legislative union with Scotland, effected in 1707 by statute 6 Anne, c. 8, only to mention that it brought an accession to the English (which thereby became the British) House of Commons, of thirty members for counties, and exactly half that number for cities and boroughs; exhibiting between the numerical amount of the county and that of the borough representation a proportion quite the reverse, not only of that which existed in England, but of that which had previously appeared in the Scottish parliamentary representation.

The same reign presents us with an enactment of the

British House of Commons respecting its own future constitution, totally different in character from those of William III.'s time just referred to. This is the very important Act (9 Anne, c. 5), which established the qualification of landed property for English members, whether for counties or boroughs. In the reign of Henry VI., which gave birth to the enactment disfranchising the smaller county freeholders, was passed an Act, in the same spirit, restricting the choice of those freeholders who still retained the franchise. The very terms of this statute imply, that in the case of the counties as in that of the boroughs, there was originally no legal distinction between the qualification of the electors and that of the elected, but that the former were simply called upon to return two of their own number according to their own best discretion. The circumstance, too, of the daily expenses uniformly paid under legal obligation by the constituents to each representative while absent on parliamentary duty, may in this place be properly mentioned as a striking evidence of the fact, that the qualification of considerable property, how much soever it might be regarded in the judgment of the constituents, was, originally, not at all contemplated by the law. The statute in question (23 Henry VI., c. 14) declares, that thenceforward the county representatives shall be 'notable knights of the same counties, or shall be able to be knights,' that is, shall have freehold to the amount of 40*l* per annum, and that no man shall be eligible 'that stands in the degree of a yeoman or under.' On this legal footing the county representation remained until the ninth year of Queen Anne, when not only was the landed property qualification re-enacted for the counties on a scale nearly proportioned to the decrease in the nominal value of money, but an unprecedented step was taken, by including in the very same clause of the same Act a provision, that while every knight of the shire should possess a freehold or copyhold estate of clear 600*l*. per annum, so also every citizen, burgess, or baron of the Cinque Ports should have the like landed qualification to the amount of 300*l*. per annum. The statute of the 1st of George I., commonly called the Septennial Act, which extended the legal duration of parliaments from three years to seven, how cogent soever might be the political motives of the chief promoters of the measure, is another memorable instance of the lengths to which the House of Commons could now venture in dealing in a wholesale manner with the elective rights of its constituents.

After all that royal prerogative and parliamentary enactment had now done to undermine the originally free and independent basis of the national representation in general, little more seemed necessary in order to render the subversion of this part of the legislative constitution complete; and the door was permanently shut against the prosecution of any scheme for reforming or improving the constitution of the Commons' House, originating within that assembly. It would require volumes to describe the operation and effects of this great political machine during the period that followed—the period of its most absolute perversion to ministerial and to party purposes, and at the same time to trace the fearful and fluctuating conflict thus excited and protracted between the vitiated constitution of the house and the growing strength and intelligence of public opinion. It is no matter of conjecture; it is a momentous and significant fact in the history of this great political institution, that it was 'the pressure from without,' and that alone, forcibly stimulated, indeed, by the recent success of a popular revolution of government in a neighbouring country, that drove the House of Commons to compel, first the formation of a ministry pledged to amend the constitution of the representative body in general, and secondly, by adopting and perseveringly supporting the measure of amelioration consequently brought forward, to force the acquiescence of the hereditary chamber of the legislature in this degree of purification of the representative.

One of the most important operations of the British House of Commons during the period above mentioned, was the enacting of the statute, passed in 1800 and taking effect from January 1st, 1801, by which it incorporated the parliamentary representation of Ireland with that of Great Britain. For the previous history of the Anglo-Irish representation, and the degree of alteration made in it by the Act of Union, we refer to [PARLIAMENT OF IRELAND]. Sixty-four members for counties, thirty-five for cities and boroughs, and one for Dublin university, were thus added to the number of the British House of Commons. In this instance, as in that of the Scottish union, the antient proportion between the city and borough representation was reversed, and an additional weight consequently thrown into the scale of the county representation of the United Kingdom at large.

We now proceed to exhibit, in one general view, the state of the representative system of the United Kingdom as now existing, showing at the same time, under each of the appropriate heads, the nature and extent of the several important changes made by the Reform Acts of 1832. The following tabular form, to which reference is made in the subsequent paragraphs, will be found, on comparing it with the historical summary given under BOROUGHS OF ENGLAND AND WALES, to afford, besides the convenience of chronological and alphabetical arrangement, some interesting and useful illustration of the progress of the English borough system. In considering this table we must observe, that in stating the counties and boroughs as sending members continuously from the several reigns in which they respectively began to send, we have been obliged, for the sake of brevity and clearness, to abstain from distinguishing some of the boroughs, and, we believe, two or three of the northern counties, which, for reasons given above, and in our account of the boroughs of England and Wales, occasionally omitted sending in some of the earlier reigns. Nor could we conveniently specify such boroughs as, having once sent members, discontinued electing a long time ago, and have never since resumed their parliamentary existence. The most important as well as interesting object in exhibiting such a view, has appeared to us to be the showing the several epochs of English representative history that respectively gave birth to the parliamentary constituencies which subsisted at the introduction of the Reform Bill in 1831.

Parliamentary Representation of the United Kingdom, before the Reform Acts of 1832.

Dublin . . . 1

With the aid of the foregoing table we now lay before the reader a view of the present state of the representative system, carefully indicating the alterations made by the acts of 1832 in those branches of it to which they apply.

1. *As regards the number and local limits of constituencies, and the number of representatives.*

COUNTIES.

England and Wales.—The number of county constituencies before the Reform Act was 52, returning collectively 94 members: viz. two for each county of England, except Yorkshire; four for the latter county; and one for each county of Wales. The several cities and boroughs which are counties-corporate were excluded from the limits of the several shires within which they were locally situated: viz., from Carmarthenshire, the town of Carmarthen; from Kent, the city of Canterbury; from Cheshire, that of Chester; from Warwickshire, that of Coventry; from Gloucestershire, that of Gloucester; from Yorkshire, the town of Kingston-upon-Hull, and the city of York; from Lincolnshire, the city of Lincoln; from Middlesex, London; from Northumberland, the town of Newcastle-upon-Tyne; from Dorsetshire, Poole; from Worcestershire, the city of Worcester; and from Hampshire, the town of Southampton.

The act has increased the number of constituencies to 82, by dividing into two electoral districts each of the 25 counties in schedule (F) of the act, and marked F in the foregoing table: constituting each of the three ridings of Yorkshire a distinct district for the same purpose; and in like manner severing the Lindsey division of Lincolnshire from the other portion of that county, and the Isle of Wight from Hampshire. The number of county members is raised from 94 to 159, as follows:—Two are assigned to each division of each of the counties in schedule (F) and of Lincolnshire; two to each riding of Yorkshire: one member is added to each of the seven undivided counties included in schedule (F 2) of the act, and marked F 2 in the above table; one to each of the three Welsh counties of Carmarthen, Denbigh, and Glamorgan; and one is assigned to the Isle of Wight, separately from Hampshire.

Scotland.—The number (30) of county constituencies and of county members, as existing before the Reform Act, remains unaltered. But for two of the 27 counties mentioned in the foregoing table, as returning one member each, viz., Elgin and Ross, are substituted Bute and Caithness, which before sent only in alternate parliaments; and the remaining six counties, instead of electing alternately as before, now return jointly as follows:—Elgin and Nairn, one member; Ross and Cromarty, one; Clackmannan and Kinross, one. To the last-mentioned electoral district are also annexed three whole parishes, and part of two others, detached by the act from the shire of Perth, and one entire parish from that of Stirling. And, to obviate the inconvenience arising from the great irregularities in the boundaries of some of the Scottish counties, it is enacted that all detached portions of counties shall, for election purposes, be held to be in the several shires within which they are locally included.

Ireland.—The Irish Reform Act of 1832 has made no change in the county representation as to local limits or number of representatives; two members being still returned for each of the 32 counties enumerated in the preceding table.

CITIES AND BOROUGHS.

England and Wales.—The whole number of the cities and boroughs, or districts of boroughs, previously to the act, was 208, returning collectively 415 members. For total extinction as parliamentary boroughs, those were selected the population of each of which, according to the parliamentary returns of 1831, was below 2000. Within this description came the 56 English boroughs in the above list to which the letter A is prefixed, returning collectively 111 members. For reduction from the sending of two representatives to that of one only, those were selected the population of which, according to the same census, was under 4000. These were the 30 English boroughs in the above list to which the letter B is prefixed, from whose proportion of the representation 30 members were deducted; to these must be added two members deducted from the four formerly sent by the united boroughs of Weymouth and Melcombe Regis; making altogether a total of 143 borough members struck out of the old frame of the representation.

Of the distribution of this number among the new constituencies of the United Kingdom (as the total number of members remains unaltered), we have here to speak only of the portion assigned to the populous parliamentary boroughs now created in England and Wales. To these was transferred the election of 63 members out of the 143 thus taken from the old constituencies. Of the 43 new boroughs, 22, containing each a population of 25,000 and upwards, and including the great metropolitan districts, were empowered to return two members each; and the remaining 21, containing each 12,000 inhabitants or upwards, to send one member.

New Boroughs created by the Reform Act, passed June 7, 1832.

To Montgomery—	Llanfyllin Llanidloes Machynlleth Newtown Welsh Pool	Montgomeryshire
To Pembroke—	Milford	Pembrokeshire
To Radnor—	Presteigne	Radnorshire

In the important matter of *boundaries*, two great objects were to be attained; the fixing of appropriate limits to the boroughs of large population newly created, and the extending the limits of the old boroughs in the many instances in which a considerable population had, in the lapse of ages, accumulated without the ancient boundary. A large agricultural district was also annexed, for the purposes of parliamentary election, to each of the four boroughs of Aylesbury, Cricklade, East Retford, and New Shoreham. And as regards the Welsh districts of boroughs, it may be observed that the principle laid down in the act of Henry VIII., that *all* the boroughs in each county should share the representation—a principle which the arbitrary interference of the Crown, and the decisions of election committees, had since rendered in many instances inoperative—was now restored in its full vigour.

Scotland.—The number of town representatives is raised from 15 to 23; two instead of one being assigned to the city of Edinburgh; two to that of Glasgow, detached from the district of burghs numbered 9 in the foregoing table; one to that of Aberdeen, detached from district No. 4; one each to the towns of Dundee and Perth, detached from district No. 5; and one each to the large modern towns of Greenock and Paisley. As regards the districts of burghs, their number, their general locality, and their proportion of members (one to each district), remain nearly as before; but as regards the particular places joined in the respective districts, the following alterations are made by the Reform Act:—To district No. 1 is added the town of Cromarty in the shire of that name, not before included in any district. To No. 3, in like manner, is added the town of Peterhead, in the shire of Aberdeen, before unrepresented. To No. 4, from which Aberdeen is detached, Forfar is transferred from No. 5; and the towns of Dundee and Perth being also detached from No. 5, the two remaining towns of that district, Cupar and St. Andrews, are now joined with the five previously forming district No. 6. The city of Glasgow being detached from district No. 9, the towns of Kilmarnock and

Port-Glasgow, before unrepresented, are added to it. In district No. 11, Peebles and Selkirk being disfranchised by the act, and merged in the counties in which they are respectively situated, the three formerly unrepresented towns of Airdrie, Falkirk, and Hamilton, are joined in their stead with the antient burghs of Lanark and Linlithgow. In No. 12, in like manner, the burgh of Rothsay is merged in the shire of Bute, and the town of Oban is substituted in its place. The great increase in the population of the maritime vicinity of Edinburgh has occasioned the creating of one district entirely new, comprising the three towns of Leith, Portobello, and Musselburgh, without, however, increasing the previous number of districts, the towns of No. 5, in the old arrangement, being all distributed in the new as above described. New and suitable parliamentary limits are assigned in the schedules of the act, as well to the several antient boroughs as to those newly created.

Ireland.—In the list of cities and boroughs sending representatives, no alteration is made by the Irish Reform Act; but two members each, instead of one, are assigned to Belfast, Galwây, Limerick, and Waterford, thus raising the whole town representation from 35 members to 39. The limits of the parliamentary boroughs are defined, and to the greater number of them new limits are assigned, by the Boundary Act annexed.

UNIVERSITIES.

One member is added by the Irish Reform Act to the one previously returned by the university of Dublin.

2. *Elective Franchise.*

COUNTIES.

England and Wales.—Until the Reform Act, the parliamentary franchise in counties had remained without extension or alteration, as limited full three centuries before by the statutes of the 8th and 10th of Henry VI., the former of which confined the right to such 'as had freehold land or tenement to the value of 40*s.* by the year at least above all charges;' the latter to 'people *dwelling and resident* within the county, &c., whereof every man shall have freehold to the value of 40*s.* by the year. In order to render a man a freeholder, and complete his qualification for voting, it was necessary, not only that he should have a freehold interest in his lands and tenements, but that he should hold them by freehold tenure: consequently copyholders, holding by what is technically termed *base* tenure, as well as *termors*, having only a chattel interest in their estates, were excluded from voting. Doubts having been raised as to the right of copyholders, it was expressly enacted by the 31 Geo. II., c. 14, that no person holding by copy of court-roll should be thereby entitled to vote. The Reform Act extends the franchise by admitting not only copyholders, but leaseholders, and even occupiers, under certain limitations; and abridges it in some cases of freeholds not of inheritance, as also in all cases of land situate in a city or borough, and which being occupied by the proprietor would give him a parliamentary vote for that city or borough. In establishing the right to the county franchise, questions of tenure and interest have become of comparatively little importance, except as they are connected with value; for now what is commonly, though improperly, called a tenant at will (that is, from year to year) occupying land of the annual rent of 50*l.* has a right to vote for a county, without reference to the tenure by which the lessor holds the land, or the interest that he may have in it. By 18 Geo. II., c. 18, s. 5, it was enacted that no person should vote for a county unless he had been for *twelve* calendar months in actual possession of the rents and profits to his own use, except in particular cases. But by the statute of 1832, by s. 26 it is enacted, that no person shall be registered as a freeholder or copyholder, unless he was in actual possession of the rents and profits for *six* months previous to the last day of July of the year wherein he claims to be registered. Leaseholders and their assignees, and yearly tenants, must have occupied for *twelve* months before the same period, except in the cases excepted by the abovementioned statute of George II. Value, therefore, has now become the criterion upon which, in many cases, the right of voting wholly depends; and in all cases it is a most material subject of inquiry, in order to determine in what character, whether as freeholder, copyholder, leaseholder, or occupier, an elector should make his claim to be registered.

1. If lands or tenements are held at a yearly rent of 50*l.*, bare occupation, as tenant from year to year, is sufficient to qualify; no further interest in the lands, &c., being necessary, and it being immaterial by what tenure they are held. 2. So also is the occupation of lands, &c., of 50*l.* yearly value, as sub-lessee or assignee of any under-lease created originally for a term of not less than 20 years, how small a portion soever of the original term may remain unexpired. 3. The original lessee of a term created originally for 20 years, of lands of 50*l.* yearly value, or the assignee of such term, is entitled to vote in like manner, whether or not he is the occupier of such lands. 4. The occupier of lands of 10*l.* yearly value, as sub-lessee or assignee of any underlease of a term of not less than 60 years. 5. So likewise the original lessee or the assignee of such a term of the lands of 10*l.* yearly value, is entitled, whether occupying or not; nor is the nature of the tenure material in any of the above cases; but twelve months' possession previous to the last day of July is required in all. 6. The being seised of an estate—whether of inheritance or for a life or lives—whether freehold, copyhold, or of any other tenure, to the like yearly value of 10*l.*, entitles.

Freehold lands or tenements of 40*s.* yearly value are still sufficient to give a vote in the four following cases:—

1. If it be an estate of inheritance. 2. If not an estate of inheritance, but only an estate for life or lives, if the elector was seised previously to the 7th of June, 1832 (the day on which the act received the royal assent), and continues so seised at the time of registration and of voting. 3. If acquired subsequently to that day, if the elector be in actual and *bonâ fide* occupation at the time of registration and of voting. 4. Or if acquired subsequently to that day, if it came to the elector by marriage, marriage settlement, devise, or promotion to any benefice or any office.

Of freehold or copyhold estates six months' possession, and of leasehold estates twelve months', is required, previously to the last day of July, in the year of registration, except they come by descent, succession, marriage, marriage settlement, devise, or promotion, &c.

Now, also, it has become material to consider how the lands or tenements are locally situated: for if they are freehold within a city or borough, and in the freeholder's own occupation, so as to confer a right to vote for such city or borough,—or if copyhold or leasehold, and occupied by him or any one else so as to give the right of voting for such city or borough to him or any other person,—they cease to qualify for a county vote.

However, by the 16th section of the act, an express reservation is made of all *existing* rights of suffrage possessed by county freeholders, provided they are duly registered according to the provisions of the act itself.

Scotland.—Under George II. enactments were made which rendered the proving of the old forty-shilling votes yet more difficult, so that many more of them disappeared, and at the close of the last century very few remained. Although the Scottish act of 1681 enacted that the right of voting should be in persons publicly infeoffed in property *or* superiority of lands of 40*s.* old extent, or of 400*l.* Scots valued rent, thus making a distinction, it should seem, between property and superiority, yet it was constantly interpreted to mean that superiors, that is, tenants-in-chief, or persons holding immediately of the crown, were *alone* entitled to vote. Thus proprietors of estates, of whatever value, holding from a subject, were excluded from the franchise. It is computed that in several counties nearly one-half the lands were held in this manner, and in the whole kingdom one-fifth of the lands were so held. The class of landholders thus excluded comprised not only the middling and smaller gentry, and the industrious yeomen and farmers who had inherited or acquired some portion of landed property, but also some men of estates worth from 500*l.* to 2000*l.* per annum; while many persons, who had not the smallest actual interest in the land, possessed and exercised the elective franchise. When a person of great landed property wished to multiply the votes at his command, his course was, to surrender his charter to the crown, to appoint a number of his confidential friends, to whom the crown parcelled out his estates in lots of 400*l.* Scots valued rent, and then to take charters from those friends for the real property, thus leaving them apparently the immediate tenants of the crown, and consequently all entitled to vote. This operation being open as well to peers as to great commoners, they availed themselves of it accordingly, thus depreciating or extinguishing the franchises of the smaller proprietors. This legal fraud began in the last century, and was chiefly practised subsequently to the accession of George III. Among the various modes by which it was performed, the most common were by life-rent charters, by charters on *wadset* or mortgage, and by charters in fee. The parliamentary representation of the Scottish counties therefore had, according to the expression of a learned lord, 'completely slid from its basis.' The total number of county voters, as compared with the number of persons directly interested in the property of the soil, was extremely small, and of these the number of real votes scarcely exceeded that of the fictitious ones.

The new basis of county suffrage appears, by the Reform Act for Scotland, to be assimilated, as closely as the difference between the modes of possessing and occupying lands, &c., in the two countries will permit, to the system established for England and Wales. While the old class of rights to the suffrage are preserved to the individuals in actual possession of them before March 1st, 1831, provision is made against their perpetuation; while the body of electors newly admitted consists of owners to the value of 10*l.* a year,—of leaseholders for 57 years or for life, whose clear yearly interest is not less than 10*l.*—of leaseholders for 19 years where such yearly interest is worth not less than 50*l.*,—of yearly tenants whose rent is not less than 50*l.* per annum,—and of all tenants whatsoever who have paid for their interest in their holding an amount not less than 300*l.* The same difference is made as in the English act, between the freeholder and the mere occupier, as to the *six* months' proprietorship required in the former case and the *twelve* months' occupancy in the latter; and the like exceptions from this condition as to the length of possession in favour of cases wherein either ownership or lease comes to a person by inheritance, marriage, marriage settlement, "*mortis causâ* disposition," or appointment to any place or office.

IRELAND.—The act of union made no alteration in the parliamentary suffrage of the Irish counties. The qualification of a freeholder remained the same as before, a clear annual forty-shilling interest for a life: and as it was customary in Ireland to grant leases on lives, freeholders were thus created whose votes, from their extreme poverty, and consequent inability to discharge their legal obligations to their landlord, were disposable by him as a matter of course. This practice of multiplying freeholds for election purposes merely was carried to an excessive and most mischievous extent, reducing the franchise almost to universal suffrage, among individuals who, by the very instrument by which they were professedly made free, were reduced to the most abject state of political bondage. Thus many of the counties, in choosing their representatives, lay under the absolute dictation of some great territorial proprietor; and there were few in which a coalition of two or three of the principal landowners would not determine the election according to their own wishes. Under these circumstances, the provision of the Catholic Emancipation Act of 1829, which raised the freehold qualification in the counties of Ireland from 40*s.* to 10*l.*, can hardly be regarded as a virtual disfranchisement.

The whole civil organization of Ireland having been introduced directly from England, and the system of tenures in particular being the same in both countries, the provisions of the Irish Reform Act which have reference to the territorial franchise are more strictly analogous to those of the act for England than those of the Scottish act could well be made, at least in appearance. The existing freehold rights being preserved here, as in the other two divisions of the empire, to their individual possessors, and the 10*l.* freehold franchise being already established by the above-mentioned provision of the act of 1829, the classes of electors newly created are—1, the 10*l.* copyholders; 2, lessees or assignees having a clear yearly interest of 10*l.* in a leasehold created originally for 60 years or upwards, or of 20*l.* in a leasehold of not less than 14 years, whether in their actual occupancy or not; 3, sub-lessees or assignees of any underlease in either of the two cases just mentioned, actually occupying; 4, the immediate lessees or assignees, and they only, having a 10*l.* yearly interest in a 20*l.* lease, and actually occupying. The like provision is made as in the English act, against any title to the county franchise being derived from any holding whatever that would entitle to vote for a city or borough.

CITIES AND BOROUGHS.

ENGLAND AND WALES.—The want of any uniform basis of suffrage in the parliamentary boroughs, the endless diversity of the claims to its exercise derived from the various political as well as local influences that had operated upon them in the course of ages,—a diversity which the numerous, various, and often conflicting decisions of election committees of the House of Commons had additionally complicated and confused—was one of the most grievous defects of the old representative system. The generally prevailing custom, too, that the non-residence of borough voters entailed no disqualification, was one of the most serious evils comprised under this head. The new act has prepared the way for sweeping off all the claims to the franchise founded on the old and long-abused titles to borough freedom, by establishing a uniform qualification, resting chiefly on the basis of inhabitancy.

It provides, that in every city or borough which shall return members, every male person of full age and not subject to any legal incapacity, who shall occupy, within such city or borough, or within any place sharing in elections with it, as owner or tenant, any house, warehouse, counting-house, shop, or other building, either separately or jointly with any land, of the clear yearly value of not less than 10*l.*, shall, if duly registered, as directed in another part of the act, be entitled to vote in the election of members for such city or borough; provided always, that no such person shall be so registered in any year, unless he shall have occupied such premises for twelve calendar months previous to the last day of July in that year; nor unless such person, where there shall be a rate for the relief of the poor, shall have been rated to all rates for the relief of the poor made during such his occupation; nor unless such person shall have paid, on or before the 20th of July in the same year, all the poors' rates and assessed taxes due from him previously to the 6th of April preceding; provided also, that no such person shall be so registered unless he shall have resided for six calendar months previous to the last day of July within the city or borough, or within the place sharing in the election, or within seven miles thereof. The premises in respect of the occupation of which any person shall be entitled to be registered as a voter, need not be always *the same* premises, but may be different premises occupied in *immediate* succession by such person during the twelve calendar months previous to the last day of July: such person having paid, on or before the 20th of July, all the poors' rates and assessed taxes due before the 6th of April preceding, in respect of *all* such premises so occupied by him in succession.—Furthermore, when any premises in any such city or borough, or place sharing in the election, shall be *jointly* occupied by more persons than one, each of such joint occupiers shall be entitled to vote, in case the clear yearly value of such premises shall be of an amount which, when divided by the number of such occupiers, shall give a sum of not less than 10*l.* for each occupier. And in every city, borough, or place sharing in election, it shall be lawful for any person occupying as above specified in any parish or township in which there shall be a rate for the relief of the poor, to claim to be rated; and upon such occupier so claiming, and actually paying or tendering the full amount of the rates, the overseers are to put the name of such occupier upon the rates; and in case such overseers shall neglect or refuse so to do, such occupier shall nevertheless be deemed to have been rated.

The formerly anomalous position of cities and towns which are counties of themselves, as regards the possession of the elective franchise, is rectified by the act. Such counties of cities and towns are now included, for the purposes of county elections, in the several counties at large, or divisions of counties, in which they are locally situated—with this restriction only as regards freeholds *for life*;—that no person shall be entitled to vote in the election of knights of the shire, or of members for any city or town a county of itself, in respect of any freehold whereof such person may be seised for his own life, or for the life of another, or for any lives, except such person shall be in the actual occupation, or except the same shall have come by marriage, marriage settlement, devise, or promotion to any benefice or to any office, or except the same shall be of the clear yearly value of not less than 10*l.* It is further provided that in every city or town being a county of itself, in the election for which freeholders or burgage tenants, either with or without any superadded qualification, now have a right to vote, every such freeholder or burgage tenant shall be entitled to vote, if duly registered; but no such person shall be so registered in respect of any freehold or burgage tenement, unless he shall have been in actual possession thereof, or in receipt of the rents and profits for his own use, for twelve calendar months previous to the last day of July (except where the same shall have come to him, within such twelve months, by descent, succession, marriage, marriage settlement, devise, or promotion to any benefice or office), nor unless he shall have resided for six calendar months previous to the last day of July within such city or town, or within seven miles of it;—the limits of such city or town a county of itself, being, for the purposes of this enactment, those settled by the general parliamentary Boundary Act for England and Wales. Similar provision as to length of occupancy, &c., is made in the case of persons having a previous freehold qualification to vote for any of the boroughs of Aylesbury, Cricklade, East Retford, or New Shoreham.

Such are the provisions which constitute what is popularly called, by reference to their most prominent feature, 'the ten-pound householder qualification.'

But as in the settling of the places which were thenceforward to elect, and in apportioning the members, the new act made a large compromise with the old system, so also it made no inconsiderable one, for a season at least, in sparing to a certain extent the rights to the parliamentary franchise grounded on the old titles to borough freedom. In all such cases, however, it imposes the very important condition of *residence*. It provides that every person who would have been entitled to vote in the election of members for any city or borough as a burgess or freeman, or in the city of London as a freeman and liveryman, shall be entitled to vote if duly registered; and that every other person having, previous to the act, a right to vote in the election for any city or borough by virtue of any other qualification than those already mentioned, shall retain such right so long as he shall be qualified as an elector according to the usages and customs of such city or borough, or any law in force at the passing of the act, and shall be entitled to vote if duly registered; but in both of the above cases it is enacted that no such person shall be so registered unless he shall, on the last day of July, be qualified in such manner as would entitle him then to vote if such day were the day of election; nor unless for six calendar months previous to that day he shall have resided within such city or borough, or within seven miles from the place where the poll shall heretofore have been taken, or, in the case of a contributory borough, within seven miles of such borough. As regards the second class of voters last mentioned, it is further enacted that every such person shall for ever cease to enjoy such right of voting if his name shall have been omitted for two successive years from the register of parliamentary voters for such city or borough, unless he shall have been so omitted in consequence of his having received parochial relief within twelve calendar months previous to the last day of July in any year, or of his absence on naval or military service.

The expedient to which, to serve party purposes during the agitation of the Reform measure, many of the governing bodies of corporations had resorted, of admitting unusually large numbers of freemen, occasioned the following limitations of the above reservation of the elective franchise of freemen to be introduced into the act, viz.:—That no person who shall have been elected, made, or admitted a burgess or freeman since March 1st, 1831, otherwise than in respect of birth or servitude, or who shall hereafter be so, shall be entitled to vote; that no person shall be entitled as a burgess or freeman in respect of birth, unless his right be originally derived from or through some person who was a burgess or freeman, or was entitled to be admitted as such, before the said 1st of March, 1831, or from some person who since that time shall have become, or shall hereafter become, a burgess or freeman in respect of servitude; and that no person shall be entitled to vote for any city or borough (except it be a county of itself) in respect of any estate or interest in any burgage tenement or freehold which shall have been acquired by such person since the same 1st of March, 1831, unless it shall have come to such person previously to the passing of this act, by descent, succession, marriage, marriage-settlement, devise, or promotion to any benefice or office.

It is also provided in general that no person shall be entitled to be registered in any year as a voter for any city or borough who shall, within twelve calendar months previous to the last day of July in that year, have received parochial relief or other alms which, according to the previously existing law of parliament, disqualified from voting.

SCOTLAND.—Owing to the previous absence of all pretence or shadow of popular suffrage in the Scottish boroughs, the revolution made in their parliamentary constituencies by the Reform Act of 1832 is effected simply, completely, and at once. The franchise is taken from the members of the town councils and their delegates, in whom as such it was before exclusively vested, and a 10*l.* qualification, by ownership or occupancy, substituted in its place, with the like conditions, as in the English act, of twelve months' previous occupancy, payment of assessed taxes, registration, and non-receipt of parochial relief.

IRELAND.—In the Irish cities and boroughs the change immediately worked by the Parliamentary Reform Act is relatively greater than in England, owing chiefly to the fact that the municipal corporations of the former country existed in a state yet more thoroughly anomalous and corrupt than those of the latter. [CORPORATIONS (MUNICIPAL) OF IRELAND.] Here again, the actually existing and the inchoate titles to the parliamentary suffrage being reserved, as in the English act, on condition of residence within seven miles, and honorary freemen created since March 30, 1831, being excluded, the 10*l.* ownership or occupancy qualification is established as the new basis of suffrage, on condition of registration with *six* months' previous occupancy and payment of all rates due for more than one half-year. Reservation is also made, as in the English boroughs, of rights by freehold under 10*l.*, when accruing before the passing of the act, by descent, marriage, &c. The clause of the Catholic Emancipation Act, which raised the freehold qualification in counties at large to 10*l.*, left it at the old amount of 40*s.* in the several counties of cities and towns; but the Reform Act raises it there to the same scale as in the counties at large (only reserving for life the existing 40*s.* rights), and at the same time gives the parliamentary franchise for such corporate counties to the same classes of leaseholders, and on the same conditions, whom it admits in the counties at large.

UNIVERSITIES.

In the two English universities the parliamentary suffrage is independent of residence, property, or occupancy, being vested in the doctors and masters of arts of Cambridge and Oxford respectively, so long as they keep their names on the boards of their respective colleges. In that of Dublin, in like manner, it is possessed by the fellows, scholars, and graduates of Trinity College, on the like condition.

The establishment of a general and uniform system of registration of voters, calculated to obviate much of the inconvenience of contested returns, is another very important feature of the Reform Acts; for the various and rather complicated details of which we must refer the reader to the acts themselves.

Having thus given a view of the qualifications for exercising the parliamentary franchise as now established throughout the British Islands, it remains to notice the principal of those legal disqualifications which are of a personal nature, and operate independently of all proprietorship or occupancy.

Every woman, of whatever age, and however independently situated as to property and social relations, is as much excluded from voting as from being elected. As to age in male persons, the only exception is that which excludes all minors, that is, all who have not completed their twenty-first year. The exception which regards *aliens* is so natural and obvious that the bare mention of it may here suffice, as this is not the place in which to examine the various difficulties that in many cases have arisen and still arise in strictly defining who are aliens and who are not. By the antient 'law of parliament,' which forms an integral portion of the common law, lunatics are very reasonably incapacitated, as also are paupers in city or borough elections. It was resolved by the House of Commons in 1699 (14th December), that 'no peer of parliament' has a right to vote for members of that house. After the Union with

Ireland, this resolution, which was usually repeated at the beginning of every session, was altered into the following form: 'That no peer of this realm, except such peer of that part of the United Kingdom called Ireland as shall for the time being be actually elected, and shall not have declined to serve, for any county, city, or borough of Great Britain, hath any right to give his vote in the election of any member to serve in parliament.' The vast increase, since the commencement of the last century, owing to the establishment of so many new branches of revenue, in the number of persons employed immediately by the crown as revenue-collectors, occasioned the enactment of several statutes of exclusion from the parliamentary franchise. Thus the 22nd George III., c. 41, excludes every class of officers concerned in the collection or management of the excise, customs, stamp duties, salt duties, window and house duties, or in any department of the business of the post-office. By 3 George IV., c. 56, s. 14, it was first enacted that no justice, receiver, surveyor, or constable, appointed by that act at any one of the eight police-offices of the English metropolis, shall be capable of voting for Middlesex, Surrey, Westminster, or Southwark; and by 10 George IV., c. 44, which established the new system of police in certain districts of the metropolis (the operation of which has since been extended to meet the local extension of the police-system), it was enacted that no justice, receiver, or person belonging to the police-force appointed by virtue of that act, shall be capable of voting for Middlesex, Surrey, Hertfordshire, Essex, or Kent, or for any city or borough within the metropolitan district. Persons legally convicted of perjury or subornation of perjury, or of taking or asking any bribe, are thereby for ever incapacitated from voting.

As regards religious grounds of disqualification in general, it should be observed, that as no oaths are now required to be taken, nor declarations to be made, as a preliminary either to registration or to voting, all such disabilities as might have arisen from refusal to take or make them are of course removed.

3. *Qualifications of Candidates.*

Of the close relation so long subsisting between the grounds of the elective franchise and of eligibility, and which had sprung from their original identity, we find distinct traces in the similarity between the heads of disqualification in either case. Women, minors, aliens, and lunatics are of course excluded in the latter case as well as in the former. It would be needless to remark, that peers of *parliament*, that is, actual members of the House of Lords, are ineligible to the House of Commons, except in order to point out this distinction—that any Irish peer, not being among the twenty-eight sitting in the House of Lords for the time being as representatives of the Irish peerage, and being, therefore, though a peer of the realm, not a peer of parliament, is eligible to represent any constituency in the United Kingdom, although such is not the case with Scotch peers who are not representative peers. No person concerned in the management of any duties or taxes created since 1692 (except commissioners of the treasury), nor any officer of the excise, customs, stamps, &c., nor any person holding any office under the crown created since 1705, is eligible. In like manner, pensioners under the crown during pleasure, or for a term of years, are wholly excluded. Any member, however, who accepts an office of profit under the crown existing prior to 1705, though he thereby vacates his seat, is capable of being re-elected. Contractors with government are ineligible; and it is enacted, that if any person so disqualified shall sit in the house, he shall forfeit 500*l.* per day for so doing; and that if any person having a contract of this nature admits a member of the house to share in it, he shall forfeit 500*l.* to the prosecutor. Again, by 3 Geo. IV., c. 55, no police justice of the metropolis can sit in parliament.

The twelve judges for the time being are disqualified, as sitting in the House of Peers, though, as judges, they have merely a *consultative* voice there. The vice-chancellor also is excluded, though the master of the rolls is not. The exclusion of ecclesiastics from seats in the commons' house, seems not only to have been a natural result of the presumed urgency of their pastoral duties, but to have reference to the period when their share of those general contributions to the extraordinary exigencies of the state, the business of settling which, as we have already seen, first gave form and consistency to the parliamentary representation in general, was yielded by them as a distinct body. Sheriffs of counties, and mayors and bailiffs of boroughs, as being themselves returning-officers in parliamentary elections, are ineligible for the several districts respectively for which it is their duty to make returns.

The repeal of the Corporation and Test Acts in 1828, and the passing of the Catholic Emancipation Act in 1829, have worked one very important alteration in the constitution of the commons' house, by removing nearly altogether the widely-operating religious disqualifications which previously existed. The engagement, 'on the true faith of a Christian,' to abstain from all designs hostile to the Church as by law established, which the latter act has substituted for the oath and declaration formerly required, excludes no man professing Christianity in however general terms, and seems indeed to have no effective operation but against individuals of the Jewish race and creed, to whose admission this bar is still opposed.

Such are the chief personal disqualifications, at common law or by statute, from sitting in the commons' house of parliament; presenting, as already remarked, a general analogy to those existing against the voter.

We now come to the other branch of the subject, the qualifications by property and residence; and here, in the case of the English and Irish representation at least, the analogy no longer holds good. The landed qualification for an English, Welsh, or Irish member, remains as before the Reform Acts, viz., for a county member an estate of 600*l.* a year, and for a city or borough member, of 300*l.* To represent a university no property qualification is requisite. The only *personal* exceptions from this condition are in favour of the eldest sons of peers, of *bishops having seats in the House of Lords*, and of persons legally qualified to be county members. The qualifying property may be situated in any part of England, Wales, Ireland, or Berwick-upon-Tweed. As regards the Scottish part of the representation, it is worthy of especial remark, that the property qualifications enacted for England within a very few years after the union with Scotland, have never been extended to the latter portion of the kingdom; and that consequently the conditions of suffrage and of eligibility have remained there, according to the original constitution of the representative system in both countries, one and the same, excepting only the antiently essential condition of *residence*, which has long been done away throughout the United Kingdom without any reservation or limitation whatever; and excepting also that the Scottish Reform Act of 1832 has rendered unnecessary for county members the qualification of an *elector* formerly required.

Issuing of Writs for a General Election; Election Proceedings and Returns.

An essential and very important part of the representative machinery is that which regards the due transmission from the central to the local authority of the summons to elect, the superintendence of the election proceedings, and the due return from the local to the central authority of the names of the individuals chosen. When the Lord Chancellor, the highest officer of state, has received the written command of the king in council for the summoning of a new parliament, he thereupon sends his warrant or order to the highest ministerial officer acting under him, the clerk of the crown in chancery, to prepare and issue the *writs*, or written authorities for that purpose, to the several sheriffs, whether of counties at large or of counties corporate.

In the early periods of our history, when the shire-motes, or county courts, were held regularly once a month, and the borough courts once a week or once a fortnight, there was no need to incur the trouble and inconvenience of a special meeting of the members of those courts, that is, of the freeholders in the former case and the burgesses in the latter, to elect the parliamentary representatives; and accordingly the sheriff was simply required to cause the election of the county members at the next county court, held in the regular course, or at an adjourned meeting of that court, in case such adjournment were necessary in order to allow time for giving due notice of the election. It was not until the importance of the county courts declined, that a different arrangement became necessary; nor was it until the 25th of George III., that it was enacted that the sheriff, on receipt of the writ, should call a *special* county court for the purpose of the election.

The writ, thus addressed under the great seal to the sheriff of a county at large, requires him not only to cause the election of the county representatives, but also of those of each city and borough within his jurisdiction. And accordingly, on receiving this command, he issues a *precept* under his own seal to the head of each municipality enjoying the elective franchise, which precept is to be returned to him within a limited time, together with the name of the person or persons chosen*; in like manner as he himself is bound to return, before a certain day previous to that on which the parliament is summoned to assemble, to the clerk of the crown, from whom he received it, the writ, with the names of the persons chosen, whether as county or as borough members. Such, in brief, as regards the returning-officers and responsible conductors of elections, has been the system from the commencement of the general representation.

In fourteen of the forty-three new and populous parliamentary boroughs created by the Reform Act for England and Wales, which had already a municipal or other chief civil officer or officers in whom this function could be appropriately vested, it is so entrusted by the Act. As regards the others, it is provided, that the sheriff of the respective counties shall, in the month of March in each year, by writing under his hand, to be delivered to the clerk of the peace for that county within a week from its date, and be by him filed with the records of his office, appoint for each of such boroughs a fit person resident therein to be the returning-officer until the nomination to be made in the March following. In case of such person's death or incapacity from sickness or any other sufficient impediment, the sheriff, on notice thereof, is forthwith to appoint in his stead a fit person, resident as aforesaid, to be the returning-officer for the remainder of the year. No person so nominated as returning-officer shall, after the expiration of his office, be compellable thereafter to serve again in the same office. Neither shall any person in holy orders, nor any churchwarden or overseer of the poor, be so appointed; nor shall any person so nominated be appointed a churchwarden or overseer during the time he shall be such returning-officer. Any person qualified to serve in parliament is exempted from such nomination as a returning-officer, if within one week after receiving notice of such appointment he make oath of his qualification before any justice, and forthwith notify the same to the sheriff. In accordance, however, with all previous usage, it is provided that 'in case his majesty shall be pleased to grant his royal charter of incorporation to any of the said boroughs named in the said schedules (C) and (D), which are not now incorporated, and shall by such charter give power to elect a mayor or other chief municipal officer for any such borough, then and in every such case such mayor or other chief municipal officer for the time being shall be the only returning-officer for such borough; and the provisions hereinbefore contained with regard to the nomination and appointment of a returning-officer for such borough shall thenceforth cease and determine.'

The division of both counties and boroughs into convenient polling-districts,—the shortening of the time of polling in contested elections, from the old period of fifteen days to two days in England, Wales, and Scotland, and to five in Ireland,—the restriction of inquiry at the poll into the elector's right to the ascertaining the identity of name and qualification with those contained in the register of voters (thus abolishing the old tediously litigious practice of election scrutinies),—and the limitation of the necessary expense of election proceedings, borne by the candidates or their proposers,—are among the more important of the recent improvements. For details, as we have already done in the case of the new system of registration, we must refer to the several Reform Acts of 1832.

Having thus given, we believe, a tolerably just though succinct view of the history and present state of the representative system of the British empire, so far as it can be distinctly shown without continual reference to the other branches of the legislature, we refer for an account of the organization and operations of the Commons, 'in parliament assembled' to a subsequent volume of this work. [Parliament, Imperial.]

There too may be the fit occasion for offering some indications of the future changes in its relative position as a branch of the legislature, to which the revolution recently commenced in its internal constitution must eventually lead. A word as to the progress of this internal revolution itself must conclude the present notice.

We have seen how the popular representation arose, first as a convenient, then as a necessary appendage to the feudal parliament of the Anglo-Normans. We have seen how, as early at least as the parliamentary settlement of the crown upon the house of Lancaster, that popular representation, under the title of the House of Commons, had become an effective, integral, independent, and solemnly recognized branch of the legislature. We have traced, from that period downwards, the twofold operation, of the crown in undermining this equal and sometimes preponderating independence of the Commons' House, and of that House itself in contracting the limits and abridging the rights of the constituent bodies, until the original constitution of the representative body itself was absolutely subverted. And last of all we have seen that which, in the present day, it is most interesting to consider,—the re-action of an enlarged and enlightened public opinion on the legal constitution of the House. In an historical view it is far less important to examine the merits of the late measures of representative amelioration in detail, than to mark the maturity of a new political element which they indicate, and the new line of constitutional progression which they have begun. No matter that the Reform Acts, as they are called, have made but a compromise with the exceeding corruptions and anomalies of the old system, and have left some of its most important usurpations untouched: no matter that the Commons' House, which in the days of its pristine vigour was democratic in the fullest sense of the term, is still, though somewhat popularized by the recent changes, a highly aristocratic body: we do not the less find in these changes a successful effort of the national intelligence and will, not so much to replace the legislative representation on the basis on which it stood at the close of the fourteenth century, and which, from the causes we have previously stated, was fixed without any scientific or symmetrical proportioning even of the number of representatives to that of constituents. but to mould it into some shape more accordant with the present advanced state of general information in the great body of the people; to render it, in short, a popular representation in fact as well as in name. Towards this point, how much soever they have fallen short of it, the late alterations by parliamentary enactment distinctly tend The spirit that predominates in them plainly shows from what quarter the impulse came to which they owe their being; and it is a reasonable, at least, if not a necessary inference, that nothing short of a retrogression of the public intelligence can prevent the impulse from being repeated until the great object we have stated shall be completely attained.

COMMONS, IRISH HOUSE OF. [Parliament of Ireland.]

COMMONS, DOCTORS'. [Doctors' Commons.]

COMMUNION (the Latin *communio*, the Greek κοινωνία, *koinónia*) is used to designate the uniformity of belief by which a number of persons are united in one denomination or church, as the Roman Catholic, Anglican, or Lutheran communion. *Communio* is employed repeatedly in this sense in the canons of the Council of Elvira (Illiberitanum) A.D. 313. For the examination and comparison of scriptural passages, containing the words κοινωνία and κοινωνεῖν, the Greek Concordances of the New Testament may be consulted.

Communion is used more especially for the common or public act of sharing or participating in the sacrament, eucharist, or Lord's Supper. Of the origin and use of the word communion in this sense an account is given by Casaubon, *Exercitat.* 16, § 30. During the first three centuries the communion was celebrated every Sunday. (Bingham's *Origines Ecclesiasticæ*, vol. v. c. 9.) It was subsequently administered only three times in the year, namely, at Easter, Whitsuntide, and Christmas. By the general council of Lateran, in 1215, it was decreed, in order to check the apparent inclination in many to neglect it entirely, that every one should at least communicate at Easter, that is, once a-year. This injunction was afterwards renewed by the council of Trent. For an ample account of the antient communion service, *Missa Fidelium*, as well as of the ante-communion service, *Missa Catechumenorum*, we refer to Bingham, vol. v. c. 1 to 9

---

* In the universities, the vice-chancellor, as returning-officer, receives and returns the sheriff's precept of election.

There was one form for the clergy, a second for the laity (vol. vi. c. 2 and 3), and a third and lowest form for strangers or foreigners. Degradation of the clergy to the lay form of communicating in one kind, that is, with bread and no wine, appears to have been an antient mode of canonical punishment. (*Apost. Can.* c. 14.) The bread appears never to have been omitted: the difference between communicating under one or two species or kinds, as it is termed, being solely in the omission or inclusion of the wine. The communion in two kinds seems to have continued in the Latin church until the end of the 11th century; for in 1099 Pope Paschal II. decreed that little children only should omit the wine, and that the wine alone should be given to those who, from extreme illness, could not swallow the bread. After this period the custom began to prevail of taking the wine by sopping it into the bread instead of drinking it out of the chalice. A letter by Ernulphus, bishop of Rochester, who died in 1124, commends this expedient for several reasons, one of the quaintest of which is, to avoid the profanation of wasting the consecrated wine by the dipping of bushy beards into the chalice. The communion under one species, that is, with bread alone, was authorized in 1415 by a decree of the council of Constance, and was confirmed by the council of Trent in 1562: but, with the exception of the Latin church, all the various sects of Christians have retained the communion under two species. During the first seven centuries the mixing of water with the wine was very generally considered as indispensable to the proper and efficient performance of the eucharistic rite. Justin Martyr, in his 'Apology,' written probably about the end of the first or beginning of the second century, observes that the mode of communicating was with a chalice of wine and *water*. It is unnecessary to quote passages from the subsequent fathers in confirmation of this fact. They all appear to have believed the water to be an essential ingredient; and several (Cyprian, *Epist.* 63, and Athanas. *in Psal.* 74) assign as the reason of it, that the pure wine of the mystic chalice represents the unmixed nature of God; the pure water represents the nature of faithful Christians; and the commixture of the wine and water represents the union of God and the faithful. A decree of the Œcumenic council, A.D. 691, denounces the Armenians as heretics for celebrating the communion with wine unmixed with water; and the 32nd canon of the council of Trullo decrees the deposition of every bishop or priest who shall omit the water. From the writings of Germain, patriarch of Constantinople; of Cabasilas; of Simeon of Thessalonica; of Balsamon, patriarch of Antioch; of Goar, in his Euchologia; and from the Greek Ritual, it appears to have been a long established custom in the Greek church to dilute the eucharistic wine with *hot* water, and to administer the mixture hot. To these remarks on the matter of the eucharist, we may add that Epiphanius (*Hæres.* c. 49) and Augustin (*Hæres.* c. 28) speak of an antient sect of Christians in Phrygia, followers of Montanus, who were called Artotyrites (ἄρτος, τυρός), because, in the communion, they used not bread and wine, but bread and cheese. (Pluquet, *Dict. des Hérésies.*) Others, the followers of Tatian, in the second century, made use of bread and water without wine, and hence were called Aquarians, and Hydroparastai. (Epiphan. *de Hæres.* 47; Augustin *de Hæres.* c. 25; Cyprian, *Epist.* 63.) This sect is also spoken of by Clemens Alexandrinus, and Chrysostom, and in the fifth century it was revived, with a declaration of motives of sobriety. There appears to have been a custom of communicating with consecrated bread and milk, for it is condemned by the council of Braga, in Spain, A.D. 675. The prevalent report in the first centuries, that the Christians celebrated the communion with flour which was kneaded in or with bread which was dipped in the blood of infants, slain or punctured for this purpose, appears to be applicable only to the Christian sects included under the denomination of Gnostics and Montanists; at least several of the Catholic fathers, in repelling the accusation from the orthodox, distinctly fix it upon these heretical sects. (Epiphan. *Hæres.* 26 and 48; Philastrius, *Hæres. Bib. Patr.* tom. 4, p. 13; Cyril, *Catech.* 16, p. 178; Augustin, *Hæres.* c. 26; Tertull. l. 2, *ad Uxor.* c. 5; Baronius, *An.* 120-129.) Until the seventh century the communion bread was that commonly used for food; a particular kind began then to be prepared exclusively for the purpose, of a circular form, and impressed with the sign of the cross. The Greek church adopts a leavened bread, but the Roman church has it unleavened; and this difference has been the cause of much controversy, though it seems easy to decide which kind was used by Jesus, the last supper having been on one of the 'days of unleavened bread,' when no other kind could be eaten in the land of Judæa. It has been a subject of still greater contention whether the proper posture of communicants is that of sitting, reclining, kneeling, or standing. In the third century standing appears to have been the usual posture. See Euseb. *Hist.* l. vii. c. 9; Tertull. *De Orat.* c. ult.; Chrysost. tom. i., *Hom.* 22, p. 260, παραστῆναι τῇ ἱερᾷ τραπέζῃ. It is also a subject of dispute whether the antient Agapæ (*αἱ ἀγαπαί*), which some modern sects continue under the name of love-feasts, were identical with the celebration of the eucharist. Probably these friendly repasts, so zealously continued throughout the four first centuries, were commenced or terminated by the act of communion; for they often took place in the churches until A.D. 360, when they were excluded from the churches by the council of Laodicea, on account of their having become scenes of indecorous conviviality. Tertullian, in his *Apol.* c. 39, minutely describes the proceedings of one which was conducted with propriety. The fathers frequently speak of the consecrated elements being carried home by the communicants, who gave them to the sick, or kept them deposited in their coffers as a charm against evil spirits, or bore them as a viaticum about their persons in travelling, and in voyages by sea. (Cyprian, *de Caps.* p. 176; Basil. *Epis.* 289; Ambrose, *de Obit. Satyri*, t. iv. p. 315; Cyprian, *de Spectac.*, p. 292; Justin. Mart. *Apol.* 1; Baronius, *An.* 57, n. 151.) Among the many purposes to which the sacramental symbols have been applied, we may notice an instance related by St. Augustin (*Contr. Julian.* l. iii. c. 164) of a child born blind who was perfectly enabled to see, after his mother had put upon his eyes a poultice made of the eucharistic bread and wine. In the first centuries it was customary to bury the eucharist with the dead; and though, by the council of Carthage, A.D. 419, and the Œcumenic council in 691, the custom was condemned, it still continued to prevail; and St. Cuthbert and many others were entombed with the consecrated bread on their breasts, as a safeguard against the molestation of demons. To heighten the intensity of a solemn asseveration, a few drops of 'the vivifying blood' were sometimes put into the ink with which the signature was written. Thus, in the eighth council of Constantinople, all the bishops signed the deposition of Photius with a pen 'dipped in the blood of the Saviour.' Thus Pope Theodore signed depositions; and thus Charles the Bold signed treaties of peace. (Baronius, *An.* 648.) It appears to have been always required that, after the serving of all the communicants, any portion of the consecrated elements which might be left should be immediately eaten by the officiating priests; and by the council of Toledo, in 693, the consecration of a prudent and moderate quantity is enjoined, in order to prevent repletion from eating all that remained. Hesychius (in *Levitic.* l. 2, c. 8) says, that, in the church of Jerusalem these remnants were burned; and Evagrius (*Hist.* l. iv. c. 35) informs us that, in the churches of Constantinople, the priests sent for a school of children to eat up any large quantity of fragments. To the work entitled 'An Inquiry concerning Infant Communion in the first Ages of Christianity,' we must refer for information on that point of the subject (vol. ii. p. 75); and also to the Essays on the Eucharist, by Pierce and Waterland. In the fifth century the communion was sometimes administered by women, and they continued to officiate at the altar in Italy and France until after the tenth century. (Pope Gelasius, *Epis.* 9 *to Bishops of Lucania; Epis. Ratherius Bishop of Verona.*) In the second century the eucharist began to be celebrated in the churches with closed doors, with the exclusion of all but the initiated, on which the Pagan philosophers accused the Christians of having adopted the Eleusinian mysteries of Ceres and Bacchus, bread and wine. (Augustin. *Contr. Faustum*, l. xx. c. 13.) 'The fathers,' says the Rev. Mr. Abthorp (*Letters on Christianity*, p. 365), 'adopted the language of the Eleusinian mysteries, and most incautiously applied it to the Christian worship: especially to baptism and the eucharist.' Many learned writers have noticed some remarkable points of resemblance in the Eleusinian mysteries and the Eucharistic rites, such as their being commemorative, and designed to effect a moral regeneration (παλιγγενεσία), or new-birth. See Abthorp *ubi supra;* and Casaubon *in Baronii Ann. exercit.* xvi. p. 478. On the different sorts of communion, see Albaspinæus; Du Pin; Anton. Dominicus; and the very elaborate *Histoire de l'Eucharistie*, by l'Arroque.

COMNENI FAMILY. [Alexis Comnenus.]

COMO, the province of, in the Lombardo-Venetian kingdom, is bounded to the north by the province of Valtellina, and the Swiss cantons of Grisons and Ticino, from which it is separated by several offsets of the Rhœtian Alps; to the west by the Lago Maggiore, which divides it from the Sardinian territory, south by the province of Milan, and east by that of Bergamo. The length of the province of Como, north to south, is about forty miles, from Mount S. Giori, on the frontiers of the Grisons, to the borders of the province of Milan, near Missaglia. Its breadth is very irregular. The east or larger division of the province incloses the whole length of the lake of Como, the Larius of the Romans, a fine piece of water, long, narrow, and tortuous, full of promontories, gulfs, and little bays. Its most northern extremity forms a sort of distinct lake, called Laghetto, which is joined to the other part by a narrow channel. At the junction of the Laghetto with the great lake, the Adda, coming from Valtellina, enters it on the east side. The lake then extends nearly due south for fifteen miles; after which it divides into two branches: one to the south-west, which is about eighteen miles in length, retains the name of Lake of Como, the city of that name being at the extremity of it; the other branch runs south-east for twelve miles, and is called Lago di Lecco, from the town of that name. The Adda issues out of the lake at Lecco. The breadth of the lake is very unequal; towards the middle, just above the separation of the two branches, it is about three miles, but in most other places it is only between one and two miles. Two ridges or projections of the Rhœtian Alps encompass the basin of the lake: one proceeding from the group of the Splugen runs parallel to the west bank, and divides it from the basin of the Lake of Lugano, the level of which is more than 200 feet above that of the Lake of Como. The highest summit in this ridge, called Monte S. Giori, or Iöri Berg, which rises on the north borders of the province of Como, and between it and the Canton Ticino, is about 9000 feet above the sea. The other or east ridge is an offset of the chain which divides Valtellina from Lombardy, and which forms a high summit to the north-east of the Lake of Como, called Monte Legnone, about 9000 feet, and then runs south, parallel to the east bank of the lake, dividing the province of Como from the Val Brembana, in the province of Bergamo. These two ridges sink lower and lower as they advance to the south, until at last both merge into the great plain of Lombardy. They send out many offsets towards the lake, forming transverse valleys, which are drained by numerous streams which empty themselves into the lake. The banks of the lake are one of the most delightful regions of Italy, the climate being mild and genial, the soil productive in fruits and vegetables, and the country studded with thriving villages, and fine villas or mansions of noble and wealthy families. Sailing up the lake from Como, we see a succession of villas on both banks, the Villa d'Este, those of Tanzi, Pasta (belonging to the celebrated singer of that name), the Villa Belvedere near Blevio, and those of Mugiasca and Passalacqua near Moltrasio. Opposite Moltrasio, and on the right or east bank, is the pretty village of Torno, and the villa called Pliniana, on account of the intermittent spring which Pliny the naturalist (ii. 103) describes, and which continues to exhibit the same phenomena, which are described also, though with some discrepancy, by the younger Pliny (iv. 30). The palace of La Pliniana was built about 1570, by Anguissola, one of the four nobles of Piacenza who murdered the Duke Pier Luigi Farnese, and threw his body out of the window of the ducal palace of Piacenza. Proceeding north we see on the right Palanza, Careno, and the fine cascade of Nesso, and to the left Brienno, with groves of laurel trees, Cologno, Balbiano, with the island called Comacina opposite to it, Lenno, Cadenabbia, and La Tramezzina, which last is a small district full of hamlets and country-houses, in one of the most delightful situations on the lake. The Villa Sommariva, a splendid mansion, with a gallery of good paintings, is in this neighbourhood. On the opposite side, on the promontory which divides the two branches of Lecco and Como, is Bellagio, where Pliny's seat, which he called Comœdia, is believed by some to have been, on account of the gay appearance of the landscape. His other villa, which he calls Tragœdia, was probably at Lenno, on the west bank, where the landscape is wild and stern. (Valery, *Voyages littéraires en Italie.*)

At Bellagio is the Villa Melzi, once inhabited by the vice-president of the Italian republic in the first years of Bonaparte's dominion. Farther north on the east bank is a fine cascade, called Fiume di Latte, with a glass manufactory near it; next comes Varena, in a sheltered warm situation, where the olive, vine, and orange and lemon trees, and other southern plants are seen thriving. Higher up on the same side is Bellano, at the entrance of the Val Sassina; a district subject to very cold winds from the Alps. A wild romantic spot in this neighbourhood, where the stream Pioverna forms a cascade among the rocks, is called L'Orrido di Bellano. Farther north is Colico, from whence the high-road of the Stelvio, or Stilfser Joch, began, but it is now being continued as far as Lecco. A branch road strikes off to the left near Colico, leading by Chiavenna to the pass of the Splugen. Returning southwards by the west bank, we see Donaso, where the steam-boat from Como stops; Gravedona, a large village, with the vast marble palace of the Dukes d'Alvito; Dongo, with its iron mines and works; the castle of Musso, cut in the rock, where the Condottiere Gian Giacomo Medici of Milan, brother of Pope Pius IV., defended himself for eight months against all the forces of Francesco Sforza II., duke of Milan, whom he obliged at last to grant him 35,000 gold sequins, and a full amnesty, in 1532. Near Musso are quarries of white marble, which has been used for the cathedral of Como. Lower down are Crenna, Rezzonico (Rhœtionicum), and Menagio, another large village, from whence a road leads over the mountains to Porlezza, on the north extremity of the Lago of Lugano, which here protrudes into the province of Como.

In the triangle formed by the two south branches of the lake are two ranges of hills, one parallel to each branch, both meeting near Bellagio on the extreme point. Between these ranges is the valley called Assina, in which the river Lambro takes its source, with the town of Asso, the little lake of Sagrino, and two villages, with the classical names of Castel Marte and Proserpio. At the south entrance of the valley stands the little town of Erba, in the middle of a plain encircled by hills, the southernmost of which form the group known by the name of Colline di Brianza, which extend between the Lambro and the Adda, and on the borders of the two provinces of Como and Milan, to within a few miles of Monza. These are the nearest hills to Milan, and the favourite resort of the wealthy Milanese in the summer and autumn. They are full of mansions, country-houses and gardens, and cheerful villages, such as Merate, with a splendid villa of the Belgioioso family; Robiate, on Mount Robio, or Orobio, a name derived from that of the Orobii, the first known inhabitants of this region, and known for its good wine; Inverigo, with the fine rotunda of the marquis and architect Cagnola, and the palace Crivelli; Lurago, with the palace Sormanni; Galbiate, Brianzola, Monticello and Montebello, which was for a time the residence of General Bonaparte after his conquest of Lombardy in 1797. Near Erba are three little lakes, Alserio, Pusiano, and Annone, which are said to have once formed one lake, known to the antients by the name of Eupilis. On the banks of the Alserio are the villa Carcano, and that of Appiani, called Soldo. Parini, the amiable and moral poet of Lombardy in the last century, was a native of this district. The roads are good as in every part of Lombardy: they have been much improved of late years, considerable sums being devoted annually to this branch of administration. The communal, or cross-roads of the province of Como, cost in 1831, 268,000 livres; in 1832, 288,000: and in 1833, 252,000 livres. The length of roads repaired, or newly opened, in the province during those three years alone, was of about 200 miles. (Bollettino, *Statistico di Milano*, 1835.)

The west division of the province of Como consists of the district of Varese and the east coast of the Lago Maggiore. Varese is a bustling town near the little lake of that name, in a fine hilly country, where some of the best silk in Lombardy is produced. This is another favourite place of resort of the Milanese, and is full of handsome country-houses. On a steep hill north of Varese is the sanctuary of La Madonna del Monte, to which the country people resort in the month of September. A road leads from Varese to Laveno, where boats cross over the Lago Maggiore to Pallanza, in the Sardinian state, from whence a branch road joins the high road of the Simplon. On the Como side of the lake is Luvino, near the river Tresa, an outlet of the lake of Lugano into the Lago Maggiore. The district of Cuvio, or Valcuvio, not far from Luvino, has been lately drained of an extensive marsh. To the east of Valcuvio, and separated from it by a range of hills, is Viconago, on the west bank of the lake of Lugano, which on this side touches the province of Como, and where are lead mines and works. Towards the south end of the Lago Maggiore is the town of Angera, Anghera, or Angleria, the birth-place of Pietro Martire, who was employed at the court of Ferdinand and Isabella, and wrote 'De rebus Oceanicis et Orbe Novo Decades.' Going in a south direction towards the borders of the province of Milan, the hills gradually sink, and the southern verge of the province of Como merges into the great plain of Lombardy. The districts of Tradate and Appiano are situated at this end.

Upon the whole, the province of Como is one of the finest in north Italy. It is well cultivated, though not so fertile as the plain; it produces corn, wine, fruit, and silk. The lake abounds with fish, especially trout. The people are industrious, active, and ingenious: many distinguished artists and literary men have come from this province. Gian Battista Giovio has given a long list of them in his 'Dizionario degli Uomini Illustri della Comasca Diocesi.' A great number of young men from the mountain districts emigrate in quest of employment; many follow the trade of masons and lapidaries, as in antient times, when under the Lombard kings master-masons in Upper Italy were generally styled 'magistri Comaceni;' others go to various countries as pedlars, carrying barometers, spectacles, looking-glasses, &c., which are manufactured at Como.

There is hardly a district in all Italy that has been so often and so much celebrated in antient and modern times. The principal writers who have described the banks of the lake of Como, are the younger Pliny in his 'Epistles;' Paolo Giovio, 'Larii Lacus Descriptio;' his brother, Benedetto Giovio, 'Historiæ Patriæ;' Giambattista Giovio, 'Opusculi Patrii et Lettere Lariane;' Amoretti, 'Viaggio ai tré Laghi;' besides many others.

The province of Como contains twenty-six districts, namely, Como, first and second, Bellagio, Menagio, Porlezza, San Fedele, Dongo, Gravedona, Bellano, Laveno, Lecco, Oggiono, Canzo, Arcisate, Maccugno, Luino, Tradate, Appiano, Brivio, Missaglia, Mariano, Erba, Angera, Gavirate, Varese, and Cuvio. These contain, in all, 528 communes, and 362,000 inhabitants. (*Bollettino Statistico*, 1835.) The province is divided, for judicial purposes, into ten circondarii, with local magistrates; the civil, criminal, and commercial courts for the whole province are at Como. There are 456 elementary schools of the first and second class, attended by about 20,000 boys, and 80 female schools attended by 3130 girls, besides holiday schools, charitable foundations, and private schools authorized by the government. (*Report* of 1833.)

COMO, the capital of the province, and a bishop's see, is situated at the S.W. extremity of the lake, surrounded by hills, on which are several old castles, in 45° 48′ N. lat., and 9° 6′ E. long., 22 miles N. by W. of Milan, 16 S. by E. of Lugano, and 23 miles E. of the nearest point of the Lago Maggiore. The population of Como, with its suburbs, is 15,000. Como has a Royal Lyceum, a public gymnasium, besides a diocesan one for theological students, a college of boarders called Gallio, and an institution for female education under the direction of the nuns of St. Francis de Sales. There are besides, in the province of Como, six private gymnasia at Cernusco, Lombardone, Cugliate, Daverio, Incino, and Oltrona. (Serristori, *Saggio Statistico*, 1833.) The cathedral of Como, a structure of the middle ages, is reckoned among the fine churches of Italy. The exterior is cased with white marble. The church of St. Fedele is still older, and remarkable for its architecture. The palace of the Giovio family, called Ædes Joviæ, has a collection of antient inscriptions placed under its portico and round the court. A handsome casino, or literary club-house, has been lately built, which Valery says is superior to all the establishments of the same sort at Paris. (*Voyages Littéraires en Italie.*) The theatre is also a handsome building with a good façade. The Broletto, or old town-house, contains the public archives. The suburb called Borgo Vico, which stretches along the lake, contains several fine palaces of the nobility; that called dell' Olmo, belonging to the Odescalchi family, is the most remarkable. The Lyceum, a handsome building, erected in 1824, has a good library attached to it. On a hill south of Como, and near the road to Milan, is the old tower Del Baradello, in which Napoleone della Torre, the popular chief, and lord of Milan, being defeated by his rival, Ottone Visconti, in 1277, was shut up in an iron cage, in which he died after nineteen months' confinement. Como is the native country of the two Plinys, of Paolo Giovio, of Innocent XI. (Odescalchi), and of Alessandro Volta.

Comum is said to have been built by the Orobii, the oldest known inhabitants of the country. It was afterwards occupied by the Gauls with the rest of Insubria. In the year 196 B.C., M. C. Marcellus having defeated the Boii and the Insubres, occupied Comum. The place was afterwards ravaged by the Rhetians. C. Pompeius Strabo, father of the great Pompey, sent a colony to Comum, and Cæsar is said to have sent a fresh colony, among whom were 500 Greeks of distinguished families. It then assumed the name of Novum Comum. It has been remarked that many names of places in this neighbourhood seem to be of Greek derivation. Greek inscriptions have also been found. After the fall of the empire, Como passed under the Goths, Longobards, and Franks, and became at last an independent municipal community. It was one of the chief towns of the Guibelines in Lombardy, and as such quarrelled repeatedly with the Milanese, who took it after a long siege, and burnt it in 1127. It was afterwards gradually rebuilt where it now stands.

Como has several considerable manufactories of silks, and also of woollens. Of late years we have seen several new works from the Como press.

COMORIN, CAPE, the southern extremity of the peninsula of Hindustan, situated in the territory of the rajah of Travancore, in 8° 4′ N. lat. and 77° 37′ E. long., fourteen miles south-east from the town of Kotaur. It was noticed by Marco Polo in 1295 under the name of Cape Comari. The approach to this cape is unsafe for ships, on account of the many rocks by which it is surrounded. It is about 150 miles direct distance from the nearest point of Ceylon, and about 175 miles from Columbo.

COMORN (in Hungarian, Komárom), a county in the north-western part of Hungary, divided into two parts by the Danube, is bounded on the north-west by the county of Pressburg. That portion which lies on the left bank of the Danube is perfectly level; but the other, on the right bank, is mountainous, owing to the interposition of the Bakonye and Vertes ranges. The Danube is joined by its northern arm close to the town of Comorn, after receiving the Neutra and Waag: the Dotis is another of the numerous streams in this county. Considerable tracts, which are now swamps, were cultivated and enlivened with villages in the time of Mathias Corvinus, king of Hungary. The soil is one of the most fertile in the kingdom, and well adapted for agricultural and grazing pursuits. The climate is salubrious. The surface available for production is estimated at 596,860 acres; of which 209,800 are employed as arable land, 32,100 as pastures, 16,300 as vineyards, and 221,280 are occupied by woods and forests. The whole area is about 1127 square miles. Large herds and flocks are reared, and there is a royal stud at Babolna: there is much game, and an abundant supply of fish. Beautiful marble is got at Tandos and Dotis, and the county also produces limestone, sandstone, and coal. It is divided into 4 circles, and contains 1 town, 6 market-towns, 81 villages, and 70 privileged settlements. The population is about 120,000, mostly Magyars, of whom the majority are Calvinists.

COMORN, the chief town, is a royal free town and fortress at the eastern extremity of the island of Schütt, opposite the efflux of the Waag into the Danube. It lies in 47° 45′ N. lat. and 18° 8′ E. long. The town is irregularly built, and the streets are dark and narrrow; but it is well situated for trade, which it carries on to a great extent in grain, honey, wine, timber, and fish. It contains four Roman Catholic churches, of which that of St. Andrew is of considerable dimensions, two places of Protestant worship, a Greek church, and a synagogue; a council-house, town-hall, Roman Catholic and Protestant gymnasium, grammar school for the citizens, and hospital. It is the seat of the only native association for insuring the vessels which navigate the Danube and other Hungarian rivers, and their cargoes. To the east of the town, and at the point where the Waag and Danube form a junction, stands the maiden fortress of Comorn, which is defended by extensive works and *têtes-de-pont* on both banks of the Danube: it was built by Mathias Corvinus, and has been rendered one of the strongest places in Europe by the additional fortifications commenced in 1805. The Danube is crossed at this spot by a flying bridge as well as a bridge of boats. Comorn contains about 1160 houses, and 17,500 inhabitants.

COMORO ISLANDS are situated in the channel of Mozambique, between 11° and 13° S. lat., and 42° and 45° E. long., about 150 miles from the coast of Africa, and somewhat more from the western coast of Madagascar. They are four in number; the largest, Comoro or Angazaye, which extends about thirty miles south and north, is very little known. The principal island is Anzuan or Hinzuan, where the sovereign who calls himself sultan resides: this is the only island visited by European vessels. [Anzuan.] The third is Majotte, or rather Mayotte, which is said to have 1500 inhabitants. The smallest is Mohilla or Molalle. These islands have recently been often devastated by the Maratis, or inhabitants of the coast of Sekelava in Madagascar, who come over in large boats, besiege the fortified towns for months together, and carry away cattle and men. The population is said to have much decreased, and the smaller islands are nearly abandoned by their inhabitants.

COMPANIES, JOINT STOCK. [Joint Stock Companies.]

COMPANIES, or GUILDS. [Borough, p. 201; Collegium.]

COMPANY, in military affairs, is the body of men which constitutes one of the principal divisions of a battalion of infantry, and which corresponds to the troop in a regiment of cavalry. The strength of a company in the regiments of Guards and of the Artillery, is 120 men, but in the regular infantry, 100 men. In each battalion there is one which is denominated the grenadier company, and another bearing the name of the light company; and these are called flank companies from their stations, which, when the battalion is drawn up in line, are at its extremities. The grenadiers acquired that denomination from the grenades, or small shells, which they were appointed to throw by hand into an enemy's works; and the light companies were so called from the activity required in the men, who are frequently detached from the line in order to act as skirmishers, according to circumstances, about the battalion or brigade to which they belong. Every company of the line and militia is commanded by a captain, under whom are a lieutenant and an ensign, besides the non-commissioned officers; but in the regiment of artillery, the rifle brigade, and the corps of engineers and marines, each company has, instead of an ensign, a second lieutenant.

In France, the first formation of bodies of men under the denomination of companies, may be said to have taken place in 1373. [Cavalry.] But the institution, in that country, of what approaches nearer to the present signification of the word, occurred in 1557, when Henry II. divided a French legion into fifteen bodies of 400 men; each of which, except the two first divisions or companies, was commanded by a captain, a lieutenant, and an ensign, besides two serjeants and eight corporals. Those two companies were considered as being immediately under the command of the colonel himself, and therefore had no officer of higher rank than lieutenant. This regulation seems to have been followed in the British service, since formerly in each regiment there were two, called the colonel's companies, which were commanded by lieutenants only, who, however, were by courtesy entitled captains.

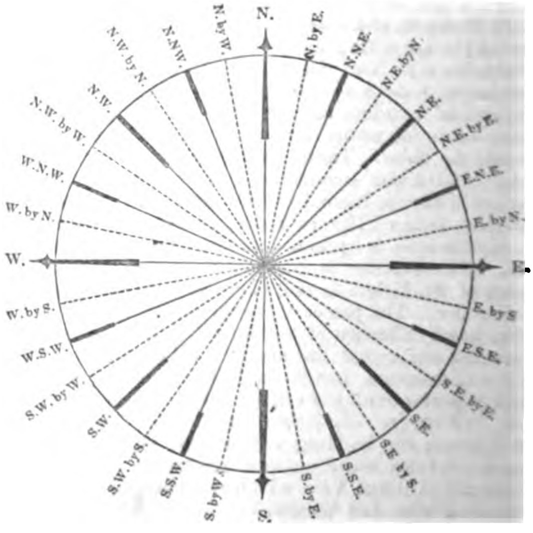
It is observed by Grose, that probably from the time of the Conquest the English infantry was divided into corps, consisting of 1000 men, which were subdivided into hundreds and tens. And he remarks that in the list of the army engaged at the siege and battle of St. Quentin in 1557, each company is stated to consist of 100 men, and to be commanded by a captain, a lieutenant, and an ensign, as at present, besides a serjeant, a harbinger, or quartermaster, and a drummer.

COMPASS, AZIMUTH, is a compass with plain sights, (generally vertical wires), attached to it in such a manner as to be moveable round a vertical axis independently of the compass-card. A pointer shows the angle which the position of the telescope, or sights, marks out on the card, that is, the bearing of the object towards which the sights are directed. This angle is the azimuth of the object, when the correction for magnetic variation is made. But when the bearings of two objects are measured, the correction need not be applied in merely determining the difference of bearings, since the error affects both equally.

The azimuth compass is a rough instrument, owing to the lightness and slender material of the compass-card, &c. When more exactness is required, a Theodolet, or some instrument of the kind, must be used.

COMPASS, THE MARINER'S. A magnetic needle balanced on a pivot, will, subject to a correction for the variation of the magnet, point out the true direction of north and south. A card bearing the points of the compass, and unalterably attached to any apparatus, such as a globe, will therefore afford the means of adjusting it north and south, if the centre of the card be made the pivot of a magnetic needle. In the mariner's compass, however, it is usual to affix the needle to the card, pointing towards its north and south point, so that the card travels with the needle; and if a pointer (fixed with respect to the ship) mark out the point on the edge of the card which lies in the line drawn through the pivot parallel to the plane which symmetrically bisects the ship, the bearing of the ship's head is shown by the part of the card to which the pointer directs for the time being. To insure the horizontality of the compass-card, the cylindrical box in which it is enclosed is supported in a hoop at opposite points, by pins projecting from it, so as to allow the box to revolve inside the hoop. This hoop is supported in the same manner on pivots, the line of which is at right angles to the first pivots; so that between the rotation of the compass-box in the hoop, and the hoop itself, the former can always find its position of equilibrium, which is the horizontal position. The small oscillations of the apparatus are immediately destroyed by the friction. The apparatus is then said to be supported on gimbles, or gimbals.

The notation of the mariner's compass is as follows: any point in the card being taken as north (marked N.), the opposite point is the south (marked S.), and the intermediate points are the east and west (E. and W.) The juxta-position of any two letters denotes the point which is half way between the points marked by these letters (N.E., N.W., S.E., S.W., north-east, north-west, &c., half way between north and east, &c.). The repetition of any of the preceding with any of the *cardinal* points (*cardo*, a hinge or pivot, points on which all the rest depend), has a similar meaning; thus E. S. E., or east-south-east, means the point which is half way between east and south-east. The intermediate points lie half way between the sixteen points hitherto explained: but instead of continuing the same notation, it is usual to express each by that one of the preceding points to which it is nearest, followed by the cardinal point towards which its departure from its nearest point leads it, the two being separated by the word 'by.' Thus the point half way between east and east-south-east, is east by south (nearest to east looking towards south). This admirable notation gives thirty-two points, as follows, which are sufficient for all purposes of description.



The distance between any two consecutive points subtends one thirty-second part of the circumference, or 11° 15′. This angle is called a point: and two objects, whose bearings differ by such an angle, are said to bear one point from each other. Thus a ship is said to sail within three points of the wind when the angle which her track makes with the line in which the wind comes is less than three times 11° 15′, or 33° 45′. The convenience of the preceding notation is combined with greater accuracy (the edge of the card being divided into degrees as well as points) by noting the number of degrees between the direction in question and the nearest point, together with the direction of departure. Thus E.N.E. 7° 21′ E., would imply a direction which makes an angle 7° 21′ with E.N.E., towards the east. If fractions be used, they mean fractions of a point: thus N.E. ¼ E. means a quarter of a point from north-east towards the east.

COMPASS, HISTORY OF THE. The knowledge of the directive power of the magnet was unknown to the Greeks, the Romans, and to European nations generally, till late in the twelfth century; and does not appear even then to have been brought into common use for nautical purposes. It has however been so known and so used in China, Japan, India, and Arabia from periods of high antiquity. Doubts, indeed, have been often expressed of the validity of the claims of the Chinese, and of the authenticity of the dates attributed to the notices of it in the grand annals of their empire: but the most careful examination of the Chinese claims does not warrant our scepticism on one point or the other. The Jesuit missionaries, who went to China in the beginning of the 17th century, were of course little likely to admit the high antiquity claimed by those annals without rigorous inquiry; nor without evidence of great force, to give up in any degree, even implicitly, the chronological authority of the Vulgate Scriptures: yet this was not only the case, but upon their return they unanimously agreed in the conviction that those records were authentic, and several of them published that conviction to the Catholic world, at no small degree of risk to their reputation for orthodoxy. No exact translation into any European language of the passages from which they drew their accounts of the directive properties of the magnet, had, however, been given till last year, when the lamented scholar Klaproth published his 'Lettre à M. A. Humboldt sur l'Invention de la Boussole,' at Paris; and a translation of the passage in question has been again given in English by Mr. Davies in his 'Early History of the Mariner's Compass,' just published in the 'British Annual for 1837.' The circumstance, from its incidental mention, seems to give greater authority to the passage. It relates to the date 2634 years before our æra.

'Houang-ti punishes Tchi-yeou at Tchou-lou.

'The Waï-ki said: Tchi-yeou bore the name of Khiang; he was related to the Emperor Yan-ti. He delighted in war and turmoil. He made swords, lances, and large cross-bows to oppress and devastate the empire. He called and brought together the chiefs of provinces: his grasping disposition and avarice exceeded all bounds. Yan-ti-yu-wang, unable any longer to keep him in check, ordered him to withdraw himself to Chao-hao, in order that he might thus detain him in the west. Tchi-yeou nevertheless persisted more and more in his perverse conduct. He crossed the river Yang-choui, ascended the Kieou-nao, and gave battle to the Emperor Yan-ti at Khoung-sang. Yan-ti was obliged to retire and seek an asylum in the plain of Tchou-lou. Hiuan-yuan (the proper name of the Emperor Houang-ti) then collected the forces of the vassals of the empire, and attacked Tchi-yeou in the plains of Tchou-lou. The latter raised a thick fog, in order that by means of the darkness he might spread confusion in the enemy's army. But Hiuan-yuan constructed a *chariot for indicating the south, in order to distinguish the four cardinal points*; by means of which he pursued Tchi-yeou and took him prisoner. He caused him to be ignominiously put to death at Tchoung-ki. The spot received, from this circumstance, the name of the plain of the broken curb.'

Other Chinese accounts vary as to language and as to circumstances relating to the personal character of Tchi-yeou; but they all agree in the statement respecting the *Tchi-nan* (or chariot of the south) being constructed by the emperor on that occasion; and it is remarkable that the very name by which the instrument is denoted, like every thing else Chinese, is retained almost unvaried from the earliest period of their history down to the present times.

Though numerous other passages of various dates speak equally explicitly of the use of the compass for land purposes, yet no mention of the use of the magnet for *navigation* occurs in any of their books that have come to the knowledge of Europeans, till the dynasty of Tsin, which lasted from the year 265 to 419 of Christ. It is in the great dictionary Poi-wen-yeu-fou; and it is there stated that 'there were then ships directed to the south by the needle.' Mr. Davies contends that this passage rather refers to the magnitude of their ships and the extent of the voyages which they performed, than to the introduction of the needle into marine affairs. In the ninth century, two Mohammedan travellers travelled into Arabia, an account of whose journey was published from an Arabic MS. (which bears internal marks of being written as early as the close of the eleventh century) by Eusebius Renaudot, at Paris, in 1718. In this it is stated that the Chinese at that period (the ninth century) traded in ships to the Persian Gulf and the Red Sea; and though the compass is not mentioned, it is utterly improbable that the Chinese should have known the directive property of the magnet, and have *used* it on land for thirty centuries, and yet not have employed it at sea. It was known on the Syrian coast before it had come into general use in Europe, as is obvious from the following passage from a MS. written in 1242, by Baïlak Kibdjaki, which is very explicit in its description of the nautical compass:—'We have to notice, amongst other properties of the magnet, that the captains who navigate the Syrian sea, when the night is so dark as to conceal from view the stars which might direct their course according to the position of the four cardinal points, take a basin full of water, which they shelter from wind by placing it in the interior of the vessel; they then drive a needle into a wooden peg or a corn-stalk, so as to form the shape of a cross, and throw it into the basin of water prepared for the purpose, on the surface of which it floats. They afterwards take a loadstone of sufficient size to fill the palm of the hand, or even smaller; bring it to the surface of the water, give to their hands a rotatory motion towards the right, so that the needle turns on the water's surface; they then suddenly and quickly withdraw their hands, when the two points of the needle face north and south. They have given me ocular demonstration of this process during our sea voyage from Syria to Alexandria in the year 640' (of the Hegira). An older passage than this might have been quoted, did the limits of our article allow of amplification; but this has been chosen on account of the distinctness of the description. When we consider the jealousy with which all knowledge was guarded by its possessors, especially that of *commercial* value, we cannot but admit that the use of the compass must have been very common at a period when a passenger was initiated into the complete knowledge of the mode of magnetising the steel needle, as well as the mode of using it.

In 1260, when Marco Polo returned from his travels in Cathaï, he is believed to have brought a knowledge of the compass, as well as other Chinese inventions, back to Europe with him; but there is no known authority for this opinion that can lay claim to authenticity. It is certain, however, that before the close of the fifteenth century, when Vasco de Gama found his way round the Cape of Good Hope, the pilots of the Indian Seas were expert in the use of sea-charts, the astrolabe, and the compass.

A passage extracted from the *Landnamabok* of Arc Frode, who lived about the close of the eleventh century, has been brought forward by Professor Hansteen to prove the use of the magnetic needle for purposes of navigation at least as early as that date, in Norway: '*for in those times seamen had no loadstone in the northern countries.*' But this passage is most probably an interpolation by the continuator of the chronicle: which view is supported both by the remark of the editor, Finæus, of the chronicle itself, as well as by the circumstance of the whole passage not being found in three different MSS. Its authentic origin cannot reach higher than the fourteenth century. (*Brit. Ann.*, p. 296.)

The mariner's compass is however minutely described by Guyot de Provins, who wrote his satire entitled 'La Bible,' about the year 1190. This has usually been assumed to contain no indication that the mariner's compass was a recent discovery, or only little known in France at the time of the composition of the satire; but Mr. Davies considers that the minuteness of the description itself, as well as other collateral evidence, proves clearly that it was an instrument at that time not only not much known, but a total novelty. Guyot, a minstrel by profession, had probably seen it in use during the crusades, to one of which most likely he had previously attached himself. At all events Cardinal de Vitry and Vincent de Beauvais, both Frenchmen, and both crusaders, writing at a later period by a quarter or half a century than Guyot, speak of it as a great curiosity which they saw in the east, and as a thing perfectly new in Europe would be spoken of. There is not hence the slightest foundation for the belief that it was used by European seamen at so early a period, though there can be but little doubt that by the middle of the thirteenth century it had come into partial use and into general knowledge; since, in one of the songs of Gauthier d'Epinois, is an *allusion*, which no one would have made had not his auditors been familiar with the magnetic needle.

Considerable doubts rest upon the character to be given to a MS. known as the Leyden MS. of Adsiger. This (which has been published by Cavallo in the supplement to his 'Treatise on Magnetism,' pp. 37—62), makes the compass known for *land* purposes in 1269, and, what is more remarkable, it does not appear to have been known to the writer, Petrus Peregrinus, as capable of use at sea, whilst its declination from the true meridian is distinctly expressed. Klaproth does not even mention this; Libri throws doubts upon the authenticity of the MS. itself; Windebanke has very recently published a commentary on it, which we have not seen; and Davies waives the discussion of it till a future period. Under these circumstances there can be no impropriety in leaving it as an open question; and we feel the more disposed to do this, as there is very clear proof that the needle was at least partially known in Europe before the period when that letter, *ad Sigerium*, was written; and moreover that it throws no especial light upon the progress of the improvement of the instrument.

It was long contended that the inventor of the compass as a *nautical* instrument was Flavio Gioja, a native of Amalfi, near Naples, and the date given by the Italians is from 1300 to 1320. It will be obvious from what we have already said, that there is no foundation for this opinion; and independently of this, the authority of the statements themselves are invalidated by an appeal to the facts which are affirmed in proof of it, as may be seen either in Klaproth's letter or in the 'British Annual.' Before this assigned period, even the *Trésor* of Brunetto Latini (the master of the Divine Dante) bears evidence that the compass was not a rarity. It is however highly probable that Gioja greatly improved the compass, either by its mode of suspension, or by the attachment of the card to the needle itself, or in some other important particular.

The French have laid claim to the discovery of the compass, or at least to the attachment of the card to the needle, from the circumstance of the north point being marked with the *fleur-de-lis;* but in the absence of all distinct evidence on this point, it is much more probable that the view taken by Mr. Davies is correct—that the figure is an *ornamented cross*, and originating in the devotion of an ignorant and superstitious age to the mere symbol. Or, again, he observes, as the compass undoubtedly came into Europe from the Arabs, the *fleur-de-lis* might possibly be a modification of the *mouasala* or dart, the name by which the Arabs called the needle.

The discovery of the variation of the needle was, generally, before the appearance of Cavallo's 'Treatise on Magnetism,' attributed to Columbus, and since that time it has been assumed as being very early known. [DECLINATION OF THE COMPASS.]

By whom the suspension, now generally used, was invented, is altogether unknown from any document, or other evidence. The suspension of the whole machine itself on two circles, whose suspending diameters are at right angles to each other, technically called gimbals (or jimbals), is however, on all hands, admitted to have been English, though we are still ignorant both of the person who invented it or the period of the invention. It appears to be traditional evidence on which the opinion rests; but a tradition in which rival nations agree, bearing on an invention which would be honourable to any one to have a power to claim, can hardly be supposed an erroneous one. Still, even in England, in the time of Queen Elizabeth, the construction was very rude in its execution.

The dip of the needle, or its *inclination*, was also the undoubted discovery of an Englishman, Robert Norman, a nautical-instrument maker at Wapping, who published an interesting account of the course of his experiments in 1594, under the title of the 'New Attractive.' [DIPPING NEEDLE and MAGNETIC INTENSITY.]

The VARIATION OF DECLINATION is also an English discovery, being made, as is well authenticated, by Stephen Burrowes, of Limehouse, and fully determined by Gillebrand, professor of geometry in Gresham College; and the diurnal variation of the declination also unquestionably belongs to another Englishman, Mr. Graham, about 1719.

After the time of Norman, it appears to have been the general practice to follow his plan, that of suspending the needle by its mechanical centre of gravity, and when it was magnetised, bringing it from the natural magnetic position to a horizontal one by means of a counter weight, which could be slid along the needle to bring it to the required position. Few attempts of any moment were made till very recently to examine the magnetic conditions and changes to which the needle was subjected, or the advantages of one form of the needle itself over another. The only improvements were those which insured greater nicety of construction; and except in this respect, the needle was, at the beginning of the nineteeth century, in precisely the same state as it was three centuries before. The two chief improvements in the completion of a needle to be aimed at, besides its accuracy of suspension, were the symmetrical diffusion of the two opposite species of magnetism in the two arms of the needle, and the communication of the greatest total directive intensity to it as a whole. The method of effecting the first of these is generally conceded to be the method of double touch, invented by our countryman Michel; and on the latter the experiments of Captain Kater have been usually held to be decisive, although it does appear that the anomalous results which he obtained, so far as the *figure* of the needle is concerned, do not justify the inference that the question is properly decided. They however leave no doubt that the greatest directive power (whatever method of magnetising be employed) is given to the needle, which has been prepared by hardening it throughout at a red heat, and then softened from the middle to within about an inch of each end, till the blue colour which arises has again disappeared. (See *Phil. Trans.*, 1821.)

The iron employed so extensively in modern vessels has created great but generally unsuspected deflections of the magnetic needle from the position which under the influence of terrestrial magnetism only it would take in any given place and at any given time. Numerous vessels have been wrecked in consequence of this alone. Mr. Barlow invented a simple apparatus, which considerably diminishes the danger from this source, and this is the last improvement which navigation, so far as the compass is connected with navigation, has received. It is described under the head [CORRECTING PLATE]. The employment of so much *malleable* iron as is usual in vessels (especially steamers) does however threaten to render the compass altogether nugatory, as is shown in the place just referred to.

COMPASSES. This term we suppose to be synonymous with *compassers*, instruments by which we compass or go round a space. We shall here only give such a general notion of different kinds of constructions as will perhaps suggest the most convenient for any particular purpose.

1. Common Compasses, or Dividers.—There are simply two pointed legs on a common pivot, for transferring distances. For drawing a circle the lower end of one of the legs is removed, and its place supplied by a holder for a pencil, or by a steel pen.

2. Hair Compasses.—One of the legs has a part attached to the upper part by a spring, so that by means of a screw a very small motion may be given to the lower end. It is convenient for very accurate dividing, but must be used with care.

3. Triangular Compasses.—These have three legs and two pivots, so that the three points of a triangle can be at once transferred. This is useful only in rough work, as the instrument is difficult to handle.

4. Proportional Compasses.—These consist of two dividing compasses with a common pivot, which, when open, present vertically opposite angles; consequently, the intervals between the points of one and the other are in the same proportion as the legs of one to the legs of the other. The pivot is a clamping screw, which can be transferred along the interval between the pairs of points, and a scale points out how to adjust the instrument to alter any line, or surface, or solid, in a given proportion. These compasses sometimes have an apparatus for slight adjustment; but on the whole we consider it as an instrument for rough work.

5. Beam Compasses.—This instrument is a cylindrical bar, perpendicular to which, with clamping screws, slide a point and a pencil. The use of it is to describe large circles, or measure large distances, the common compasses being very liable to slip when opened very wide. It is a very safe and sure construction.

6. There is a method of describing a small arc of a very large circle, as follows. An elastic rod of metal is furnished with a rigid bar, on which it can be drawn up by screws, so that the rod shall form an arc, the chord of which is a part of the bar. This may be adjusted so as to pass through three given points nearly in the same straight line, and though the curve then described by guiding the point of a pencil along the rod be not exactly an arc of a circle, yet, for all small flexures, it will come sufficiently near for practical purposes.

Many other species of compasses have been constructed, but these are all we have ever seen in use. [Calibre; Elliptic Compasses.]

COMPIEGNE, a town in France, in the department of Oise, on the left bank of the river Oise, just below the junction of the Aisne, and on the road from Paris to St. Quentin. It is 43 miles N.N.E. of Paris in a straight line, or 46 miles by the road through Senlis: in 49° 25′ N. lat. and 2° 49′ E. long.

Compiègne was originally a hunting residence of the kings of France, of the Merovingian and Carlovingian races. Charles Le Chauve founded here an abbey, and built two castles: the abbey with its church was rebuilt by Charles Le Simple. Several of the Carlovingian princes resided here, and some of them are buried here; but, under the third race, that of Capet, the town fell into some degree of neglect. In the contests of the Bourguignon and Armagnac factions, and in the wars of France and England, Compiègne changed hands frequently. It was in a sally from this place that Jeanne d'Arc was taken prisoner.

The town is agreeably situated, partly on the summit, and partly on the slope, of an eminence. The streets are badly laid out and the houses ill built, except in the neighbourhood of the château, where there are some good houses; there is a bridge over the river of three elliptical arches. There were formerly three parish churches, of which only one and a chapel of ease remain in use. The town-hall is a remarkable Gothic building, with a lofty tower rising from the roof.

A large and magnificent royal château was gradually rebuilt under Louis XV., according to the designs of the architect Gabriel. The gardens are more extensive than those of the Tuileries. This castle was the residence of Charles IV. of Spain, his queen and their suite, during the first part of their captivity in France, A.D. 1808. Here Napoleon and Maria Louisa, archduchess of Austria, first met on occasion of their marriage in 1810.

The population of Compiègne in 1832 was 8879. There are some manufactories of hosiery and cotton yarn, and a fine rope-walk; a number of boats, suited for the navigation of the Oise, are built here. There is a considerable trade carried on in corn and wood; the latter is sent to Paris by water carriage. There are a college or high school and a public library.

In the immediate neighbourhood of the town is a forest of considerable extent, used for the chase: this forest is attached to the château. A great quantity of wooden wares is made near the town for the supply of the neighbouring departments. The arrondissement of Compiègne contained, in 1832, 97,812 inhabitants.

COMPLEMENT, that magnitude which, with another, makes up a given magnitude. This is the general meaning of the term; but the most usual specific uses are as follows:—Complements of the parallelograms about the diagonal of a parallelogram: through a point in the diagonal draw parallels to the sides; the whole is then divided into two parallelograms on the diagonal, and two which only touch the diagonal at one angle. The latter pair are called by Euclid complements to the former.

The complement of an arc or angle is the arc or angle by which it falls short of a quadrant or a right angle.

The complement of a logarithm is the number by which a logarithm falls short of 10: thus comp. log. 2 is 10 — ·30103 or 9·69897.

The arithmetical complement of a number is the number by which it falls short of the next higher decimal denomination. Thus, ar. co. 936 is 1000 − 936, or 64; arith. comp. of 83 is 100 − 83, or 27. Beginning from the left, subtract every figure from 9, up to the last significant figure, which subtract from 10.

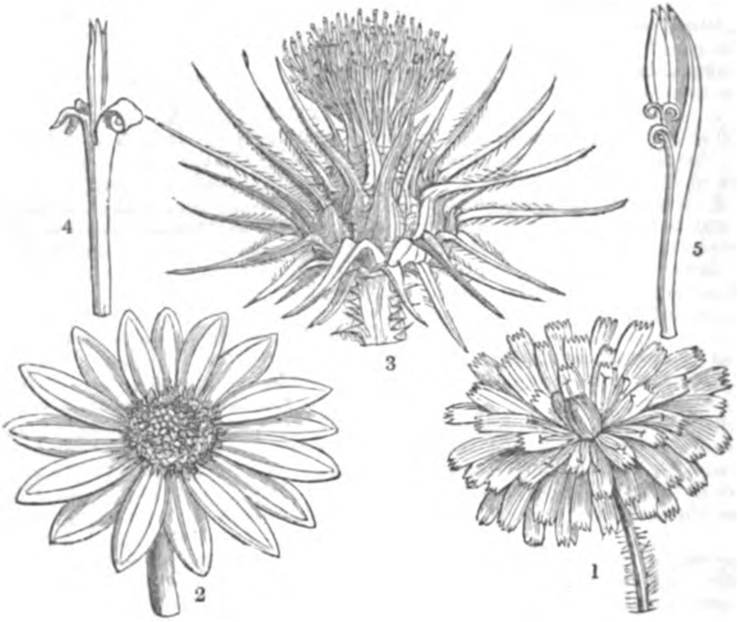
For the complement of life, see De Moivre's Hypothesis.

COMPLEXION. [Race.]

COMPLUTENSIAN POLYGLOTT. [Polyglotts.]

COMPO'SITÆ, the largest known natural order of plants, if, indeed, it is really an order, and not a group of a higher designation, consists of monopetalous exogens with syngenesious stamens, and an erect solitary ovule in a simple one-celled inferior ovary, the style of which is divided into two arms; the flowers are always arranged in dense heads, or capitula, and are surrounded by one or more external rows of bracts forming an involucre. Professor Lindley regards it as an alliance of several natural orders. It consists of herbs, shrubs, or trees, found in all parts of the world, but assuming an arborescent character only in warm latitudes: they occur in every conceivable variety of situation, are often exceedingly similar to each other in appearance, and have always been, from the birth of botany as a systematic science, the puzzle and reproach of systematists. Every succeeding writer, with a few exceptions, rendered the subject more complicated and difficult, till Cassini, a Frenchman, of good powers of observation, much patience in investigation, and a clear head, with the command of the rich materials included in the Paris herbaria, set steadily about a re-formation and re-examination of the whole order; he pointed out for the first time, that differences in the stigma are of primary importance in arranging these plants; he purged common genera of species wrongly referred to them; he boldly proposed the adoption of a host of new genera for the reception of those species, and he led the way to a logical and natural disposition of the previously unwieldy mass. Unfortunately, however, he was more skilful in separating than in combining; he stated the result of his investigations in a manner unreasonably prolix and wearisome, and he altogether failed in effecting any general reformation of the order; he was a mere man of detail. Improving upon the discoveries of Cassini, with far greater skill in forming combinations, and with fully as intimate a knowledge of the subject, the German botanist Lessing gave the world, in 1832, a synopsis of the genera of *Compositæ*, in which for the first time, a clear, compendious, intelligible view of the order was systematically taken; and his work will not cease for a long time to be a standard book of reference. But the arrangement of his matter was not favourable for comparative examination; the characters of his genera were too strictly differential for so difficult a group of plants; and moreover his style was disfigured by numerous unnecessary instances of troublesome neology. It is only within a few weeks before the appearance of this article that De Candolle, the celebrated botanist of Geneva, has achieved the difficult task of systematizing Compositæ in an unexceptionable manner. A profound master of his subject in all its bearings, with immense materials at his disposal, with a particularly clear systematic mind, and of a sound and solid judgment, he has reduced the whole subject to as satisfactory a state as any part of the vegetable kingdom. One 8vo volume of 706 pages, and containing about 4500 species, has appeared under the name of 'Prodromus Systematis Naturalis Regni Vegetabilis; pars quinta;' and the remainder, comprehending about as much more, is far advanced in the printing. It is probable that the changes in genera are too numerous in this work, as indeed is almost always the case when old enormous errors are suddenly and violently corrected; but such blemishes are hardly perceptible even to the critical eye, and are of no real importance to the general question.

The old and generally adopted plan of breaking up Compositæ into primary divisions, is that of Jussieu, which may be explained thus:—Every head of flowers, or florets, as they are technically named, has a central part, or disk, and a circumference, or ray: of these florets some are regularly tubular, with their limb cut into four or five segments; others are slit up on one side, opened flat, and turned towards the circumference of the head; the latter are named ligulate florets. When in a head of flowers all the florets are alike and ligulate, it belonged to the division CICHORACEÆ, (*fig.* 1), as in the dandelion; if the florets of the disk were tubular, and of the circumference only ligulate, it was referable to CORYMBIFERÆ (*fig.* 2), as in the marigold; and when all the florets are alike tubular, both in the disk and ray (*fig.* 3), it belonged to CYNAROCEPHALÆ, provided the involucre was at the same time stiff and ovate, as in the thistle. The latter character was necessary in order to distinguish Cynarocephalæ from those Corymbiferæ in which the ray is not developed, as common groundsel. To these three divisions a fourth has in later times being added under the name of LABIATIFLORÆ, in consequence of the florets having distinctly two lips of unequal size (*figs.* 4 and 5.)



These divisions have however been thought objectionable on several accounts, and De Candolle, following Cassini and Lessing, has trusted more to modifications of the style; the result of which is the following arrangement of the order in eight tribes.

* Tubulifloræ; namely, with the hermaphrodite florets regularly tubular, and five-(seldom four-)toothed.

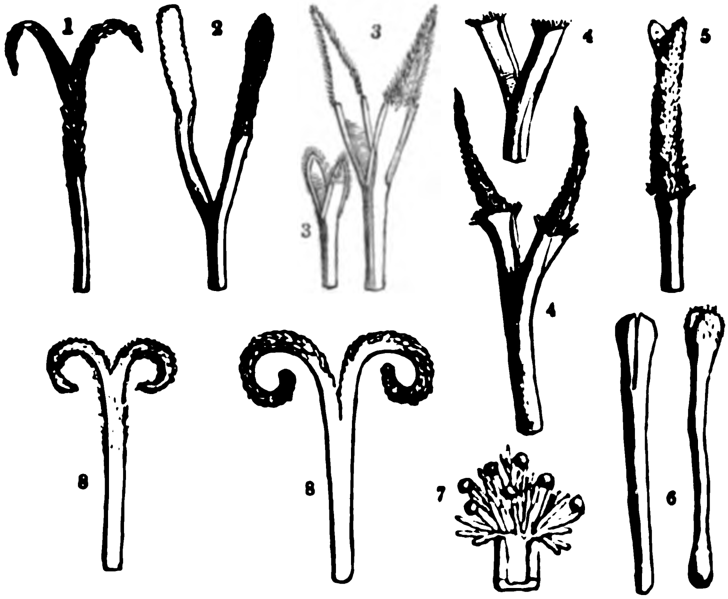
Tribe 1. VERNONIACEÆ. Style of the hermaphrodite flowers cylindrical, its arms usually lengthened and subulate, rarely short and obtuse, always equally hispid in about all the length. The true stigma ending short of the middle of the arms of the style. A part of the rayless Corymbiferæ. (*fig.* 1.)

Tribe 2. EUPATORIACEÆ. Style of the hermaphrodite flowers cylindrical, with long somewhat club-shaped arms, which are covered externally near the end with papillose down. The true stigma but little prominent, and usually ending short of the middle of the arms of the style. A part of the rayless Corymbiferæ. (*fig.* 2.)

Tribe 3. ASTEROIDEÆ. Style of the hermaphrodite flowers cylindrical, with linear arms, rather flat externally, and towards the end equally and finely downy. The true stigma produced about as far as the origin of the external down. A part of Corymbiferæ. (*fig.* 3.)

Tribe 4. SENECIONIDEÆ. Style of the hermaphrodite flowers cylindrical, with linear arms having a pencil of hairs at the point; either truncated, or produced beyond the pencil into a short cone, or a long narrow hispid appendage. The true stigma broad and prominent as far as the pencil. A part of Corymbiferæ. (*fig.* 4.)

Tribe 5. CYNAREÆ. Style of the hermaphrodite flowers thickened and knobby towards the upper end, and often



pencilled at the knob, the arms either distinct or grown together, and downy externally. The true stigma not prominent, reaching the apex of the arms, and then becoming confluent. All the Cynarocephalæ. (*fig.* 5.)

** Labiatifloræ, namely, with the hermaphrodite florets usually two-lipped.

Tribe 6. MUTISIACEÆ. Style of the hermaphrodite flowers cylindrical at the upper end, or rather knobby, the arms usually obtuse or truncated, very convex on the outside, and at the upper part covered with minute even down, or naked. (*fig.* 6.)

Tribe 7. NASSAUVIACEÆ. Style of the hermaphrodite flowers never knobby and thickened; the arms linear, rather long, truncated and pencilled at the point only. (*fig.* 7.)

*** Liguliforæ, namely with all the flowers hermaphrodite and ligulate.

Tribe 8. CICHORACEÆ. Style cylindrical at the upper end, with rather long arms, which are somewhat obtuse and equally hairy; the true stigma terminating short of the middle of the arms. (*fig.* 8.)

De Candolle estimates Compositæ at one tenth of the whole vegetable kingdom. They are in some cases soporific, as lettuce and succory; in others, they are diuretic, as various conyzas; some are tonic and stomachic, as wormwood and chamomile; but they are not of great medicinal importance to man, the last plants being the most valuable among them. Common artichokes with their succulent receptacles, and Jerusalem artichokes with their succulent tubers, are the only esculents. Many are beautiful objects to look upon, as dahlias, marigolds, coreopsis, asters, &c.

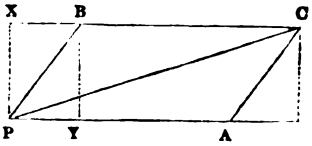
COMPOSITE ORDER. [CIVIL ARCHITECTURE; COLUMN.

COMPOSITION. In the gradual progress of mathematical language, this word has acquired a general meaning, as follows. Any one magnitude is said to be compounded of two others, when it produces the same effect as the other two put together. For instance, if we increase a length in the proportion of 3 to 7, and then increase the result in the proportion of 2 to 5, the original line is increased in the proportion of 3×2 to 7×5, or of 6 to 35. Hence the proportion of 6 to 35 is said to be the proportion compounded of (out of) the proportions of 3 to 7 and 2 to 5.

The effects of which it is in our power to form a distinct conception are of two kinds. 1. Those in which there are only two kinds imaginable, and those two diametrically opposite, with one neutral intermediate state. 2. Those in which the diametrically opposites have an infinite number of intermediate gradations. Loss or gain of money is an instance of the first; change of direction of the second. If, at the rate of an inch to a shilling, gains were measured northward from a given point, and losses southward, we could immediately make it a necessary consequence that the balance, if any, is represented by a line northward or southward, according as it is for or against. But draw a line eastward, and it will readily be admitted that such line will not present itself in any necessary connexion with a sum lost or gained, or neither lost nor gained. For if the latter, why should a line eastward be preferred to a line westward, or in any other direction?

An immense number of modes of composition will readily suggest themselves, in which addition and subtraction are the processes by which composition takes place. If I go three miles northward, and then two miles farther, I go in all $3+2$, or 5 miles northward. Other modes, as in the instance first given, will suggest themselves, in which multiplication and division are the compounding processes, and so on ad infinitum. These are all cases in which magnitude only is concerned; but whenever we have both magnitude and direction, it is plain that we have now both magnitude and direction to consider in the effect. If I go a mile northward and then a mile eastward, the whole effect, as to direction, will be, that I go to the north-east; as to magnitude, that I go not two miles, but only $\sqrt{2}$ miles, or 1·414 miles very nearly. Here is an instance in which the components are represented in magnitude and direction by two sides of a triangle, while the total effect is similarly represented by the third side. In the article CENTRE will be found various instances in which the meaning of that term implies the point at which a single action must take place, which will produce the same effect as a number of different actions produced on a number of points.

In mechanics, we have to consider the combined effects of different velocities, pressures, momenta, rotations, &c., communicated at the same moment of time to the same body. In all, the law of composition is found to be as follows—



In what sense soever the actions at P can be represented in magnitude and direction by P A and P B, in that same sense can the joint effect be represented by P C, the diagonal of the parallelogram, in both magnitude and direction: or P A and A C being the actions (A C being equal to P B in magnitude and direction), P C, the third side of the triangle, is the united action. Thus, if at the same instant we communicate motion to P in the directions P A and P B, with velocities P A and P B per second, we thereby merely communicate to P a velocity P C per second, in the direction P C. The same holds of momenta and pressures; and even if we give P two separate rotations, which would separately carry it round the axes P A and P B in angles per second which are in the same proportion as P A and P B, the joint effect is a rotation round the axis P C with an angle per second which is to the angle of P A (or P B) as P C is to P A (or P B).

We have here not to prove these things, but only to illustrate the word composition. But this we must remark, that our preconceived notions will never allow us to say that A is the effect of P and Q, and B of R and S, unless the application of P, Q, R, and S together will be the same in effect as that of A and B together. We shall show that this necessary condition of our notions of cause and effect is preserved in the method of composition just described. Let P X, B Y, and C Z be parallel to each other; then, if our law of composition be general, P B is the effect of P X and P Y. Therefore P X, P Y, and P A should be together equivalent to P C. But A Z is equal to P Y, and P Z is therefore equivalent to P A and P Y. Therefore A C should be the effect of P Z and P X, which we immediately see it is, being as much the diagonal of P X C Z as it is of P B C A.

As another, and a very curious instance of composition, we shall notice the following. Suppose x and y are to be measured, and both are subject to error, every error entailing loss in proportion to its magnitude, and causing equal loss, whether it be an error of excess or an error of defect. Suppose also that the errors are of such a kind that the average of any number of measurements is more probably right than any other. Let a and b be the sums which it would be equitable to pay for insuring x and y, that is, which should be given to any one who would agree to bear the loss on x and y separately. The sum which should then be given to one who would bear the total loss arising from the possible error in $x+y$ is not $a+b$, as might at first appear, but $\sqrt{a^2+b^2}$, or the hypothenuse of a right-angled triangle, of which a and b are as the sides.

Our limits will not allow us to enlarge on this subject we shall add the two following remarks.

1. The fact of the law of composition being the same both for velocities and pressures, has caused many writers on mechanics to confound the two, as if the one proved the other, which is neither true, nor even *very* probable. And other writers on mechanics, while proving this general law, that actions which can be represented by the two sides of a triangle produce an action which can be represented by the third side, have restricted the proposition, and seem to imagine that what they prove is true of *forces* only. This, with great deference to such a writer, we conceive M. Poisson to have done in the well-known proof at the beginning of his mechanics, a work which we may take this opportunity of saying, we hold in higher estimation than any other elementary mathematico-physical work whatsoever.

2. The difficulties of negative quantities in algebra arose from a want of generality, which gave rise to the attempt to express composition by addition only or by subtraction only, where either addition or subtraction might be requisite; and the difficulties of impossible quantities arose out of a similar deficiency, bearing the most complete analogy to trying to compound in magnitude only, in cases where both diversity of magnitude and of direction should have been considered.

COMPOSITION OF MOTION, of VELOCITY, of FORCE, &c. [COMPOSITION.]

COMPOST. [Manure.]

COMPOSTE'LA, SANTIAGO DE, the capital of the province of Galicia in Spain, and an archbishop's see, is situated on a hill near the river Tambro, in 42° 52′ N. lat., and 8° 17′ W long. It has two collegiate churches and a number of other churches and convents. Besides the great hospital, which is one of the finest in Spain, there are other hospitals and asylums for orphans and the destitute of both sexes. The number of beggars in the streets is very great. The cathedral, dedicated to the apostle St. James, is above 300 feet in length, forming a cross, with seven gates, and twenty-three chapels, some of which are ornamented with marble, jasper, and other valuable stones. The church was once very rich in silver lamps and other ornaments, but the French carried off most of the plate in 1809. The chapter is numerous and wealthy, and the archiepiscopal see is one of the richest in Spain. Among the convents, those of San Francisco and St. Martin of the Benedictines are the handsomest. The principal square, called Plaça Real, and one or two streets, are good; but the rest are steep, narrow, and ill-paved. The situation of the town itself, surrounded by mountains, which leave it a very confined horizon, is gloomy, and the climate damp and cold in winter. The university has a good library, four colleges, and the faculties of theology, philosophy, law, and medicine. There is besides a diocesan seminary for clerical students. Compostela has a population of 28,000 inhabitants, among whom are many wealthy landed proprietors. It carries on a considerable trade, and has manufactures of paper, hats, leather, ribands, and lace. (Miñano, *Diccionario Geografico de España.*)

The Moors took Compostela A.D. 997, and set fire to it. They carried away the ornaments of the cathedral and its bells, which they took to Cordova, but they were restored by the king St. Ferdinand, after he took Cordova. In the middle ages, and even down to the last century, Compostela was a place of great resort for pilgrims from all parts of Europe, who repaired to the shrine of the apostle St. James, from whose name it is often called simply Santiago, or Santiago of Galicia. It is 40 miles S. by W. of Coruña, 300 N.W. of Madrid, and 24 miles E. of the nearest point of the sea, which is at the mouth of the Tambro, S. of Cape Finisterre.

COMPOUND, that which results from composition. [Composition.]

COMPOUND ADDITION, &c. [Addition, &c.]

COMPOUND FLOWERS are the flower heads of Compositæ; they are masses of small flowers collected upon a depressed axis, or receptacle, and surrounded by an involucre of floral leaves or bracts.

COMPOUND INTEREST. [Interest.]

COMPOUND QUANTITIES [Arithmetic], quantities in which more than one unit is employed, as in 2 pounds, 3 shillings, and 6 pence; 2 miles, 3 yards, and 4 inches.

COMPOUND RATIO. [Composition, Ratio.]

COMPRESSION. [Expansion.]

COMPURGATOR. In the middle ages a practice prevailed, derived from the canon law, of permitting persons accused of certain crimes to clear themselves by purgation. In these cases the accused party formally swore to his innocence, and, in corroboration of his oath, twelve other persons, who knew him, swore that they believed in their consciences that he stated the truth. These twelve persons were called compurgators. (Ducange *ad vocem Juramentum.*) This proceeding appears to have existed among the Saxons, and, in process of time, it came into use in England in civil cases of simple contract debts. [Wager of Law.] The ceremony of canonical purgation of clerks-convict, which was nothing more than the formal oath of the party accused, and the oaths of his twelve compurgators, continued in England until it was abolished by the stat. 8 Eliz. c. 7. [Benefit of Clergy.]

COMTAT D'AVIGNON, LE, and LE COMTAT VENAISSIN, two small provinces in France, which up to the period of the French revolution, were subject to the pope, and are in most maps represented as one district, under the general designation of Le Comtat.

Le Comtat was situated between Provence, Dauphiné, and Languedoc. It was bounded on the north and north-east by Dauphiné, on the east and south by Provence, from which, on the south, it was separated by the Durance, and on the west by Languedoc, from which it was parted by the Rhône. Within these limits however was included also the principality of Orange, which was enclosed on three sides by the Le Comtat, but formed no part of it. Le Comtat is watered by various streams, the Ouvèze, the Auzon, the Nesque, the Sorgue, and others, which, uniting their waters, flow into the Rhône. The surface is not uniform; in the plains the temperature is similar to that of the neighbouring part of Provence; in the mountains it is colder: the banks of the Rhône and Durance are rendered less agreeable by the prevalence of north winds. The soil produces abundance of grain (especially excellent wheat), wine, and oil: many silk-worms are reared. There is little timber, but mulberry, olive, and almond trees are common.

The district includes some considerable towns, as Avignon, an archbishopric (population 25,956 for the town, 29,889 for the whole commune); Carpentras (pop. 6294 for the town, 9817 for the whole commune); Cavaillon (pop. 3845 for the town, 6911 for the commune); and Vaison—all these formerly were of episcopal rank: L'Isle (pop. 4717 for the town, 6052 for the whole commune); Pernes (pop. 3264 for the town, 4593 for the whole commune); Valréas (pop. 2583 for the town, 4348 for the whole commune); Bollène (pop. 2779 for the town, 4672 for the whole commune); Mazan (pop. 2670 for the town, 3851 for the whole commune); Malaucène (pop. 2209 for the town, 3069 for the whole commune); Monteux (pop. 2106 for the town, 4760 for the whole commune). Perhaps the population of the communes, which is greater in this district than in the rest of the department of Vaucluse (in which Le Comtat is now included), and the proportion which the rural population of each commune bears to that of their respective towns, may be taken as indications of the prosperity which the district enjoyed under the sway of its ecclesiastical rulers. Avignon was the capital of Le Comtat d'Avignon, and Carpentras of Le Comtat Venaissin.

During the sovereignty of the pope the government was in the hands of his vice-legate, who resided at Avignon; under him Le Comtat Venaissin was governed by a magistrate, called recteur. The dominion of the popes over Le Comtat Venaissin originated in 1273, when it was bestowed on Pope Gregory X. by Philippe III. *le Hardi*, king of France. Avignon was not acquired by the pontiffs till several years after. The whole is now comprehended in the department of Vaucluse. [Avignon; Vaucluse, Department of.]

COMTE. [Count.]

CONCAN, NORTH AND SOUTH, a district of Bejapore, comprising the entire sea-coast of that province, and extending from the sea to the Western Ghaut mountains, which form its eastern boundary. Its length from north to south is about 220 miles; its breadth in no part exceeds 50 miles, and on the average is 35 miles. The district includes many fertile places, which yield abundant harvests of rice; but the surface is in general very rough, and much intersected by steep and rocky hills. Towards the ghauts the country is in most places extremely strong, being divided by hills, intersected by ravines, and covered with thick forest. The range itself is from 2000 to 4000 feet high, and exceedingly abrupt on the west: the passes are numerous but steep, and very seldom practicable for carriages. The table-land on the east is nearly as high as many parts of the ghauts, but in general the hills rise above it to the height of from 1000 to 1500 feet.

The northern part of the chain of ghauts and that part of this district which lies at the base is inhabited chiefly by Bheels. More to the south the country is inhabited by Coolies, who are less predatory in their habits and altogether more civilized than the Bheels: these latter, although they live quietly when in the open country, resume all their wildness in places that are strong either from hills or jungle. The Bheels are small of stature and black; they wear few clothes and are always armed with bows and arrows. In the hills both Bheels and Coolies live under Naiks or chiefs of their own, who in general have been little interfered with by the Mahratta government.

The northern Concan, which extends from the district of Surat on the north, or about 20° 20′ to about 18° 50′ N. lat., was ceded to the British by the Peishwa in 1817; and the Southern Concan, which extends further in the same direction to about 16 N. lat., was obtained partly by cession and partly by conquest from the same ruler in 1817 and 1818. A great part of the Northern Concan was once held by the Portuguese, who divided the lands into large estates, which were given to Europeans, whose opulence is proved by the remains of many splendid public buildings and private dwellings which they erected, and some of which are now standing in places at present mere wastes.

The district is traversed by numerous mountain streams, but has no river of magnitude: it contains along the coast a great number of small bays and harbours, which, although they offer but little facility to commerce, serve to shelter pirates, who have always frequented this coast in great numbers. The land and sea breezes blow alternately during the twenty-four hours; the former are not felt at a greater distance than forty miles from the shore.

The Northern Concan is divided into 46 pergunnahs, containing 2111 villages and about 420,000 inhabitants. The Southern Concan comprises 47 pergunnahs and 2291 villages; and according to a census transmitted by the Bombay government to the directors of the East India Company in 1822, its native population amounted to 640,865 persons, of whom 597,150 were Hindus, 42,035 Mohammedans, and 1680 Portuguese and Jews, the descendants of former settlers. This population was

composed of males under 12 years of age .	131,933	
Above ditto . .	202,258	
		334,191
Females under 12 years .	79,784	
Above 12 years .	226,882	
		306,666
Total .		640,857

The number of houses in this southern division was 131,624; the number of ploughs, 58,535; and of oxen and buffaloes employed in agriculture, 120,089. The amount of land revenue in 1829-30 was, in

Northern Concan . .	10,65,823	rupees,
Southern . . .	10,55,421	„
Together .	21,21,244	
	or 212,124*l*.	

The roads throughout the district are for the most part very indifferent, being little more than paths, excepting near the sea-coast, where, at some of the more difficult and precipitous places, steps of an easy ascent have been constructed, mostly at the expense of private individuals.

From reports made by the government collectors in 1828, it appears that there were in the Northern Concan 137 schools, in which instruction was given to 2678 scholars; and in Southern Concan, 282 schools, with 6721 scholars, being in the proportion of one scholar to 113 inhabitants.

(*Report of Committee of House of Commons on the Affairs of India*, 1832, *Political Revenue and Public Sections; Revenue Selections from Documents in the India House.*)

CONCAVE and CONVEX—CONCAVITY and CONVEXITY. A curve or surface is concave on the side on which straight lines drawn from point to point in it fall between the curve or surface and the spectator; that side is convex on which the curve or surface falls between such lines and the spectator. A surface may be either entirely concave, as the inside of a sphere, or entirely convex, as the outside; or concave in some directions and convex in others, as the surface of a dice box, or that made by the revolution of an hyperbola about its minor axis.

For the mathematical tests of convexity or concavity, see CURVES, THEORY OF—SURFACES, THEORY OF—POINT OF CONTRARY FLEXURE.

CONCAVE LENSES. [LENS.]

CONCAVE MIRRORS. [MIRROR.]

CONCENTRIC, having the same centre; thus concentric circles are those described about the same point.

CONCEPCION. [CHILE, p. 64.]

CONCEPCION, a town of Chile, about seven miles from the shores of an extensive bay of the same name. It is situated on the north side of the river Biobio, and about a quarter of a mile from it; but during the floods the river washes the houses of the town. It occupies nearly a square mile, and is quite open, without any defences. Being built after the Spanish style, the streets cross each other at right angles with great uniformity. It has a fine open square, in which are the cathedral and the public buildings. The present site was chosen after the old city of Penco was destroyed by an earthquake in 1763, and Concepcion itself has frequently suffered from the same cause. In February, 1835, almost every house was thrown down; even the cathedral and a convent became a mass of ruins. At Talcahuano the sea is said to have risen 30 feet, and driven the vessels from their anchorage: in retiring it swept away the whole village. The population of Concepcion is estimated at about 7000. It has no manufactures and little commerce.

The bay, which is deep and commodious, is well sheltered by the fertile island of Quiriquina, which lies across the entrance with a safe channel on each side. At the head of the bay is the Puerto of Talcahuano, a small miserable town containing altogether about 1000 inhabitants, off which place ships generally lie. Along the shores of the bay are several villages, though the country is little cultivated. A bad sort of coal is found about Penco and Talcahuano. Refreshments of all kinds are plentiful; this district is indeed famous for its vines, grain, fruits, and esculent roots. Wine is made of an inferior quality, and arrow-root is raised. The bay abounds in fish: wood and water may also be had.

Talcahuano is about 240 miles to the south of Valparaiso, in 36° 42⅓′ S. lat., and 72° 57′ W. long. The tide rises about six feet. (Beechey's *Voyage to the Pacific*, &c.)

CONCERT, in music, a performance of several pieces of either vocal or instrumental music, but commonly of both, by different voices, and on various instruments. The earliest concert of which we find any record is that of the *Filarmonici*, at Vicenza, which must have been founded previously to 1565; for in that year another society, the *Incatenati*, was joined to it. But to England is due the credit of having instituted the first regular series of concerts, under the title of *The Academy of Antient Music*, which had its birth in 1710, and continued to exist upwards of eighty years. The *Concert Spirituel* of Paris was indebted for its origin to an elder brother of Philidor, the well-known composer and renowned chess-player, who in 1725 obtained a licence for the performance of sacred music during Lent. This proceeded without interruption till the French Revolution. The year 1776 is distinguished in musical history by the institution of the *Concert of Antient Music*, which became the asylum of classical compositions at a time when fashion threatened their extinction, and has ever since proved a school of music of inestimable value, by keeping alive a taste for the finest productions of the old masters. In 1791, Salomon, the celebrated violinist, commenced a series of subscription concerts at the Hanover-square Rooms, for which he engaged Haydn not only to write those twelve grand symphonies which are among the glories of the art, but to come to London to conduct their performance. These concerts went on till 1796; then ceased; and with them seemed to die away all relish for grand instrumental compositions. But in 1813, a party of eminent professors, with a view to rescue orchestral music of the highest class from the neglect into which it had fallen, formed themselves into a body under the title of the *Philharmonic Society*, and that season gave eight subscription concerts, the success of which, both as regards the main design and the support they received, was without any parallel. They constitute an æra in the art, and by their continuance act powerfully in promoting the advance of music.

Our space will only allow us to name some few other concerts which have risen up in the British metropolis, flourished for a time, then fallen to decay. Bach (John-Christian) and Abel in 1763 established subscription concerts, which have flourished for twenty years. These were succeeded by *The Professional Concert*, which, after a struggle, yielded to the enterprise and ability of Salomon. The *Vocal Concerts* of Harrison and Knyvett began in 1792 at Willis's Rooms, and were discontinued at the end of the season of 1794. They were revived in 1801 by Messrs. Bartleman, Harrison, Knyvett, and Greatorex, and conducted on a much larger scale. Their success at first was great, but they gradually fell off, and in 1821 were finally abandoned. In 1808 and two following years, Mrs. Billington, Mr. Braham, and Signor Naldi had subscription concerts at Willis's Rooms, and were opposed by Madame Catalani at the Hanover-square Rooms. In 1823, a weak and futile attempt was made to establish *British Concerts*, for the performance of music by native composers. Upon the same principle—absurd because exclusive—a concert was founded in 1834 under the name of the *Society of British Musicians*, the continuance of which has this year

(1836) been announced; but it has hitherto failed entirely in accomplishing its object. In 1833, a *Vocal Society* of thirty professional members sprang up at the Hanover-square Rooms, and gave six concerts, consisting almost entirely of vocal music, antient and modern, of every school. They are continued, and conducted on a principle so laudable that every lover of the art must feel an interest in their success.

CONCERT-PITCH, in Music, is the *pitch*—the degree of acuteness or gravity—generally adopted for some one given note, and by which every other note is, of course, governed. *Concert-pitch* has frequently much varied, and musicians have hitherto made little if any effort to obtain a fixed standard, though so desirable, and so easily established.

CONCERTO, in Music (an Italian word adopted in our language), a composition in which many performers play in concert, *i. e.* in unison, but in which some one or two instruments take rather a more prominent part than the others. Such are the concertos of Corelli, Handel, Geminiani, Avison, &c. But from the latter part of last century the term has been applied to the species of composition written for one principal instrument, with accompaniments for a full orchestra. Of this description are the piano-forte concertos of Mozart, Dussek, Cramer, Beethoven, &c.; and the violin concertos of Viotti, Rode, &c. It must be observed, however, that in the concertos of Mozart and Beethoven the orchestral parts are so full, so essential, that those compositions may, if the expression is allowable, be designated as symphonies with a piano-forte part *obbligato*.

CONCHA'CEA, M. de Blainville's eighth family—M. Rang makes it the ninth, and places it in the second division, Dimyaires, containing those families which have two muscular impressions in each valve—of his third order (*Lamellibranchiata*) of his third class (*Acephalophora*) of *Malacozoa*, or mollusks. The following is De Blainville's definition of the family. *Mantle* closed before (en avant), above, and behind, where it is prolonged by two tubes more or less long, extensile, and either separated or united; abdomen constantly provided with a foot of slightly variable form, serving for locomotion. *Shell* nearly always regular, entirely closed, equivalve; umbones curved forward; hinge dorsal, complete, that is to say, with teeth and a ligament; this last either external or internal, short, and swollen (bombé); two distinct muscular impressions united below by a *ligule* more or less large, and very often inflected or returning backwards (rentrée en arrière).'

'All the animals of this family live plunged more or less deeply in the sand or in the mud, but they are still able to come out of it sometimes.'

M. Rang thus modifies De Blainville's definition, principally for the introduction of Iridina (which according to the observations of M. Deshayes could no longer be retained among the *Submytilacea*) and *Gratelupia*, a fossil species.

'*Mantle* closed, furnished with a considerable antero-inferior opening, for the passage of a foot, and presenting two posterior tubes more or less elongated, extensile, united or separated longitudinally, the lower one serving for respiration, and the upper one for dejections. *Shell* equivalve, generally regular, rarely gaping; umbones more or less curved forwards; hinge almost always with teeth; ligament short and swollen, internal or external; muscular impressions very distinct; united by a pallial impression more or less excavated posteriorly.'

'Animals marine, rarely freshwater.'

Cuvier (last edition of *Règne Animal*), at the foot of his definition of the *Cardiacea*, the fourth family of his *Testaceous Acephala*, has the following note. 'M. de Blainville en fait la famille des *Conchacées*.' The following is Cuvier's definition of his *Cardiacés*. 'Mantle open in front (par devant), and, moreover, with two separate openings, one for respiration and the other for the excrements, which are prolonged into tubes sometimes distinct, sometimes united into a single mass. There is always a transverse muscle at each extremity, and a foot which, most frequently, serves for creeping. It may be regarded as a sufficiently general rule, that those which have long tubes live plunged in the mud or sand. One may recognize on the shell this condition of organization by the more or less developed contour (contour plus ou moins rentrant), which the impression of the attachment of the borders of the mantle describes before uniting with the impression of the posterior transverse muscle.'

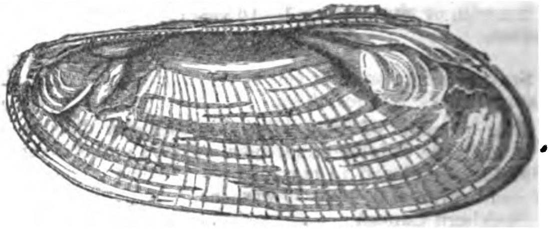
These definitions appear contradictory, but in reality they are meant to convey the same ideas. The mouth is placed anteriorly, the foot is exserted inferiorly, and the tubes open posteriorly.

*

Hinge linear and toothless—freshwater. (Rang.)

Genera. Iridina.

Animal elongated, straight, rather thick on the back, thinner towards its inferior border; mantle delicate, terminated anteriorly by a thick border, open from the anterior muscle to two-thirds of the lower border for the passage of the foot; borders of the mantle united throughout the whole posterior part, whence spring two short and unequal tubes, with no retractor muscle to the siphons; foot compressed and sharp-edged. *Shell*, with an epidermis, nacreous or iridescent internally, tolerably thick, oval oblong, elongated, inauriculated, equivalve, inequilateral, the anterior end shorter than the posterior, a little gaping at either end; umbones small and projecting but little, slightly inclined; hinge very long, linear, attenuated towards the middle, often crenulated, as it were, throughout its length; ligament very long, marginal, external; muscular impressions very distinct. Example. *Iridina exotica*, Lam., *Irid. elongata*, Sow.



[Iridina exotica, one-third of natural size.] (Sow. Gen., No 7.)

Lamarck gives the rivers of warm climates as the locality. The specimens were supposed to come from China. M. Caillaud found them in considerable abundance in the Nile; and from his specimens preserved in spirit M. Deshayes made his examination. Mr. G. B. Sowerby figures another which he considers to be a new species (*Zool. Journ.*, vol. i., tab. 2), and describes it (p. 53) under the name of *Iridina Nilotica*, obtained from Sennaar by M. Caillaud, and sent to England by M. D'Audebard. It very much resembles the species given here as an example, but its hinge margin is not crenulated or dentated. M. Deshayes, in his last edition of Lamarck, makes it identical with *Iridina exotica*, Lam. and Desh., *Anadonta exotica*, Blainv., and *Le Mutel*, Adanson.

**

Hinge with teeth.

a

Regular; hinge-teeth lateral and wide apart (marine).

Cardium (Cockle).

Animal very much rounded, having a very large cylindrical foot with a subconical termination, bent, elbow-like, about the middle, and directed forwards. The lobes of the mantle, which is bordered inferiorly by tentacular papillæ, are united posteriorly; but in the commissure, instead of elongated siphons, there are only very short ones; sometimes mere perforations in lieu of them: these are ciliated on their edge like the siphons are at their free extremity. Those parts are so short that they are without proper retractor muscles; whence it happens that the pallial impression in the shell is simple. Mouth transverse, infundibuliform, with small triangular appendages; gills short, unequal, joined upon the same line. *Shell* very much rounded, often subglobular, subcordiform or heart-shaped, equivalve with radiated ribs; borders of the valves toothed, or plaited, umbones a little curved forwards; hinge formed by four teeth in each valve, two cardinal, oblique, and two lateral and distant; ligament posterior and very short.

Geographical Distribution.—Very wide. Mr. Gray records a species, *C. radiatum*, brought home by Captain Parry (*Supplement to Voyage of* 1819–20); and the seas of almost every warm and temperate climate abound with them.

Habits.—The genus is generally found buried in sand near the shore. It has been observed in mud and gravel at depths varying from the surface of the sea to thirteen fathoms. By means of its large and long elbow-like foot it can leap well.

The species are numerous, and some grow to a very large size. M. Deshayes in his edition of Lamarck gives forty-eight, including *Hemicardium;* a form which Cuvier proposes to separate from the others, comprehending the species with compressed valves strongly carinated in the middle; observing that it is difficult to suppose that the animal is not modified in unison with this singular conformation. M. Rang corroborates Cuvier's observation, from the examination of many living individuals of *Cardium Cardissa*, the type; but M. Deshayes considers that the form can only be admitted as a section.

De Blainville divides the genus into the following sections.

1.

Species more or less gaping posteriorly, and with the ribs of the shell as large as the channellings. Example. *'Cardium exoticum.*

2.

Species not gaping, and with the ribs as large as the channellings. Example. *C. tuberculatum* (but see below).

3.

Species not gaping, with the ribs larger than the channellings. Example. *C. edule.*

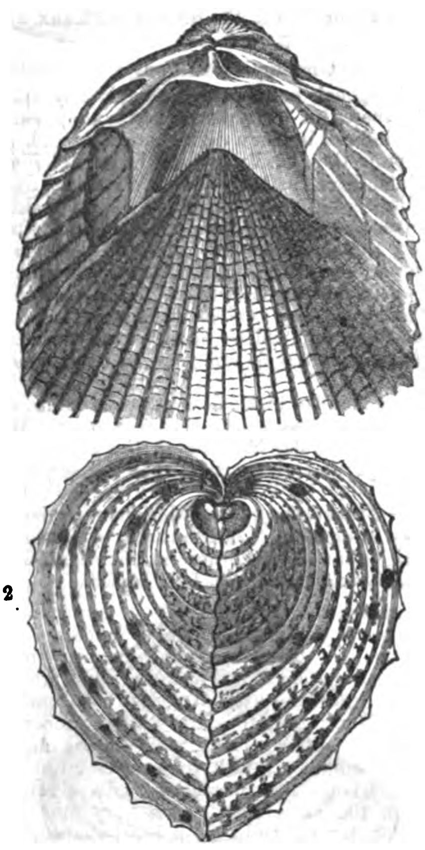
4.

Smooth, or almost smooth species. Example. *C. lævigatum.*

5.

Species whose anterior side is very short, and nearly flat. Example. *C. Hemicardium.*

Mr. G. B. Sowerby has added fourteen new species, and Mr. Broderip one, brought home by Mr. Cuming. (*Zool. Proc.*)



1. Hinge of Cardium lævigatum, natural size. 2. Cardium (Hemicardium) Cardissa, natural size; spotted variety.

Fossil Cardiadæ.

M. Deshayes in his tables gives fifty-three living species and thirty-nine fossil (tertiary), and *C. ringens, ciliare, echinatum, sulcatum, edule, tuberculatum,* and *planatum,* as both living and fossil species (tertiary). Of the recent species M. Deshayes, in his edition of Lamarck, where they are given as forty-eight, considers *Cardium Indicum, C. ringens, C. echinatum* (of which last he makes *C. tuberculatum* to be only a variety), *C. sulcatum,* and *C. edule* (common cockle) as identical with fossil species described by Brocchi and others under different names. The fossil species he makes amount to thirty. Of these he refers *C. echinatum* to its living analogue, *C. Burdigalinum* to the recent *C. Indicum, C. rhomboïdes* to the recent *C. edule,* and considers *C. diluvianum,* Lam., as identical with *C. hians,* Brocchi. The fossils occur in nearly all the fossiliferous strata from the Supracretaceous to the Grauwacke group, and appear to be most abundant in the crag, London clay and green sand, and the contemporaneous beds. *Cardiola,* Brod., was found by Mr. Murchison in the Lower Ludlow rock, *i. e.,* the lowest part of his first or uppermost *Silurian Formation.*

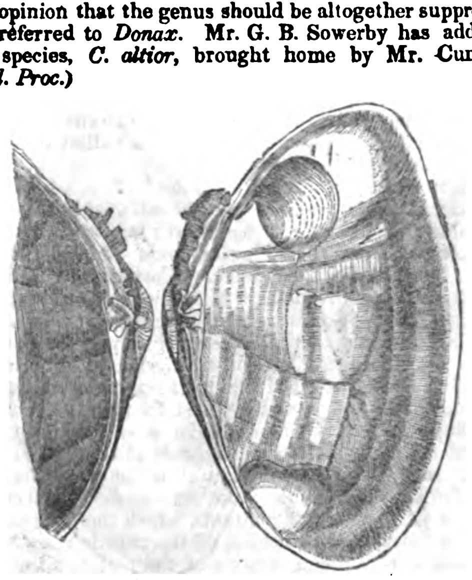
Capsa.

Animal with the mantle considerably open at its ante-inferior border for the passage of a compressed and very large foot: tubes separated and of considerable length, with tentacular papillæ at their orifices. Shell transverse, equivalve, inequilateral, not gaping; cardinal teeth diverging from a point close to the umbo, no lateral teeth in one valve, in the other, one distinct bifid cardinal tooth, and two distant very obsolete lateral ones; ligament external on the anterior side of the umbones; a large sinus in the pallial impressions.

Geographical Distribution.—Temperate and warm seas.

Habits.—Buried at a small depth in the sand, where they are said to lie with the posterior part upwards to facilitate the influx of the water for respiration. The genus has been found in sandy mud and soft mud, at depths varying from five to twelve fathoms from the surface of the sea.

Mr. G. B. Sowerby considers, that of the two species *C. lævigata* (*Donax lævigata*), and *C. Brasiliensis,* now remaining in the genus which he says appears to have been instituted by Lamarck in his Systême, adopted by Bruguière in the 'Encyclopédie Méthodique,' by De Blainville in the 'Dictionnaire des Sciences Naturelles,' and other authors, the second is figured among the *Donaces* by Bruguière: they are, he adds, very nearly related to *Donax,* but the characters of the hinge, and the absence of crenulation round the edge of the valves, will serve to distinguish them. M. Rang observes, that they approach *Donax* so closely, that the example of M. de Blainville in uniting the two may be followed. Mr. G. B. Sowerby says, that *Donax complanata,* Mont., is the only English *Capsa* with which he is acquainted; and that the genus differs from *Sanguinolaria* in not gaping, but resembles it very much in the hinge teeth. M. Deshayes remarks, that Bruguière was the founder of the genus *Capsa,* and that he assembled under it the shells to which Lamarck has since given the name of *Sanguinolaria,* and some others belonging to the *Tellinæ.* When, he adds, Lamarck dismembered the genus, he should not have retained the name of *Capsa,* on account of the confusion consequent on the application of it to shells which Bruguière placed among the *Donaces.* M. Deshayes only records two species, *C. lævigata* (Lam.) and *C. Brasiliensis* (Lam.), in his edition of Lamarck, and is of opinion that the genus should be altogether suppressed and referred to *Donax.* Mr. G. B. Sowerby has added a new species, *C. altior,* brought home by Mr. Cuming. (*Zool. Proc.*)



[Capsa Brasiliensis.

Donax.

Animal rather compressed, more or less triangular, having the mantle bordered with tentacular appendages; labial appendages large; mouth small; branchiæ very unequal, on the same side; foot compressed, trenchant, angular; tubes separate and elongated, returning into a sinus of the mantle.

Shell more or less triangular and compressed, always longer than it is high, regular, equivalve, very inequilateral, posterior side shorter than the anterior; umbones but little prominent, and nearly vertical; hinge composed of two cardinal teeth, sometimes upon both valves, sometimes upon one only, and one or two lateral teeth more or less distant; ligament external, short and swollen; muscular impressions rounded, united by a pallial impression, which is straight and very much excavated posteriorly.

Mr. G. B. Sowerby observes, that 'Lamarck is at issue with himself, when he calls the ligament posterior in *Donax;* for the sake of consistency, we must continue to call the side on which the ligament is placed, as well as the sinus in the muscular impression of the mantle, whether it be the shorter or the longer, the anterior side. We are aware that Cuvier has pointed out the impropriety of this; but the term anterior is generally adopted for the side which bears the ligament, and posterior for the opposite side.' M. Deshayes, in his edition of Lamarck, well observes, that the terms anterior and posterior, as used by that zoologist, are badly applied, and that it must not be concluded, as some have done, that the *Donaces* and *Tellinæ* have the ligament on the anterior side. Adanson, he remarks, has doubtless assisted in confirming the error, that the former have the ligament placed on the anterior side; for, probably through inadvertence, in representing the animal of a *Donax* which he names *Pamet*, he makes the foot protrude from the short side which bears the ligament, and the siphon from the long side; but, argues Deshayes, all the *Donaces* examined have the siphons coming out of the shorter side of the shell. The presence of the siphons in a great number of the conchiferous mollusks, is indicated on the shell by a more or less deep sinuosity of the pallial impression, and this sinuosity directed posteriorly shows the position and the direction of the siphons; and in Adanson's figure this sinuosity is seen on the short side, showing that the siphons there come out, and not the foot, as the neighbouring figure would indicate. The consequence, concludes M. Deshayes, is that the *Donaces* come within the rule common to the *Conchifera;* the ligament is on the posterior side where the siphons are protruded.

Geographical Distribution.—Widely extended. De Blainville says that the species occur in all parts of the world.

Habits.—Plunged in sand and sandy mud, where the animal lies with the short side of the shell uppermost, at a depth ranging from the surface of the sea to ten fathoms.

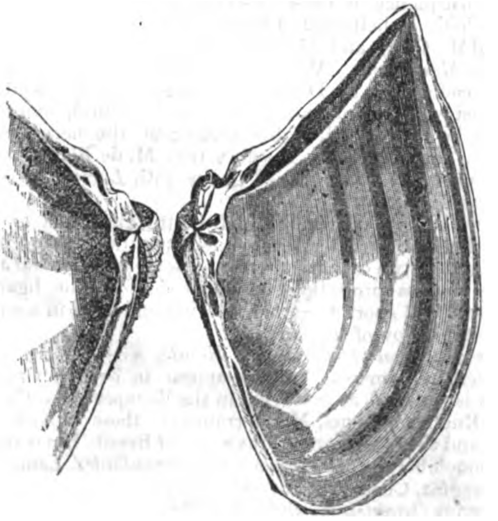
The species are numerous. M. Deshayes, in his tables, enumerates twenty-nine living, and in his edition of Lamarck thirty of these. He considers *D. pubescens*, Linn., as having been established on a young individual of *D. Scortum; D. granosa*, Lam., as a variety of *D. cuneata, D. triquetra*, as approaching nearer to the *Cytheræa* than the *Donaces; D. ringens*, as belonging to the genus *Capsa*, Lam., if Lamarck's characters are rigorously followed; *D. cardiöides* (the animal), as a proper subject for study, as it is very probable that it does not belong to the *Donaces;* the pallial impression is not notched posteriorly, and the hinge comes nearer to that of *Cardium medium* than those of the *Donaces;* and *D. Meröe* and *D. scripta*, as having more of the characters of *Cytheræa* than *Donaces.*

Lamarck divides the species into two sections: first, those which have the internal border of the valves entire or nearly so; second, those that have the internal border distinctly crenulated or dentated.

De Blainville separates them into five divisions, according to the shape, sculpture, and markings of the shell. His fifth division is the genus *Capsa* of Lamarck.

Fossil Donaces.

Mr. G. B. Sowerby in his *Genera of Shells* (No. 10, published some time since), says, 'Of fossil species there are very few: Brocchi mentions two, and we possess a small one from Bordeaux, but we believe they are very scarce.' De Blainville quotes Defrance for seventeen, three of which are analogues, one at Loignan, near Bordeaux, one in Italy, and a third in the environs of Paris. Deshayes in his tables gives fifteen fossil (tertiary), and one only (*D. elongata*), as both living and fossil (tertiary). In his edition of Lamarck, the last-mentioned species is passed without any notice of its occurring in a fossil state; but *D. trunculus* is noted as fossil, and Brocchi, Conch., t. ii., p. 537, No. 1, is quoted: nine fossil species only are given. The fossils are said to have occurred principally in the blue marls of the south of France[*], &c., the beds at Bordeaux and Dax, and in the oolitic group.



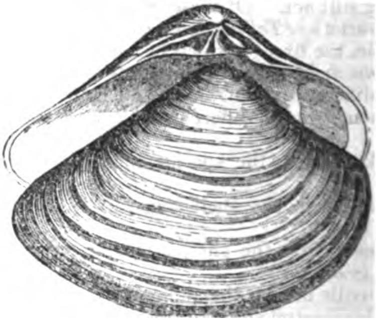
[Donax scortum.]

Gratelupia (fossil only).

Shell subtrigonal, equivalve, regular, nearly equilateral, a little attenuated at its posterior part, and presenting at the postero-inferior border a slight sinuosity; umbones very small, not projecting, hardly inclined forwards; hinge with three cardinal diverging teeth in each valve, and from three to six cardini-serial teeth, lamellar with finely dentelated edges, converging towards the summits, and situated a little below them, under the ligament; a single lateral tooth, anterior, beneath the lunule, in the left valve, corresponding with a hollow similarly situated in the right valve; ligament external, long, swollen, passing beyond the serial teeth; muscular impressions nearly equal, oval, united by a pallial impression largely and very deeply excavated posteriorly.

This genus, founded by M. Charles des Moulins, was confounded with the *Donaces* by M. de Basterot. M. Rang, who agrees with M. des Moulins on the propriety of this separation, says that there is but one species, *G. donaciformis.*

Locality.—The marine beds of Mérignac (tertiary). Mr Lea, in his interesting 'Contributions to Geology[†],' describes and figures another species, *G. Moulinsii*, from Claiborne, Alabama (America), here copied.



[Gratelupia Moulinsii.]

Tellina and Tellinides.

Animal generally very much compressed, considerably elongated; mantle moderately open at its antero-inferior part, and bordered with tentacular appendages; branchiæ unequal, on both sides; foot very much compressed, trenchant, and pointed before; tubes very much elongated, separated, and capable of being returned into a fold of the mantle.

---

[*] The term 'blue marls of the south of France,' &c., is here used in the same sense as it is by M. Marcel de Serres and in De La Beche's Manual.

[†] Philadelphia, 1833. Mr. Lea considers the strata of Claiborne as tertiary, and refers them to the same period as the London clay of England, and the Calcaire grossier of Paris,—Eocene period of Lyell.

Shell generally elongated, and very much compressed, equivalve, regular, sometimes slightly inequilateral; the anterior side not being always much longer than the posterior one, which is often angular, with a flexuous and irregular bend or fold at its lower border; umbones very small; hinge with three cardinal teeth, and two lateral ones which are often distant, with a hollow at their base in each valve; ligament posterior, swollen and elongated; a very small second ligament near the umbo; muscular impressions rounded; pallial impression straight, and very deeply excavated.

Lamarck makes the forms of *Tellina* and *Tellinides* distinctly generic. Mr. G. B. Sowerby follows Lamarck's arrangement, observing that of the *Tellinæ* there are many species, some of a form very much elongated in a transverse direction, as *T. rostrata*, *Spengleri*, &c.; others of an oval shape, some of which are rough on the outside, *T. Lingua-felis*, for example; others, again, nearly orbicular, *T. scobinata*, *T. carnaira*, &c.; a very few have one valve more flat than the other, *T. opercularis*, for instance: while both valves are remarkably deep in others, as in *T. lacunosa*. Of *Tellinides*, he says that the number of shells that may be ranged under it is rather considerable, although Lamarck has mentioned only one.

Both M. de Blainville and M. Rang think that these two forms belong to one genus, and M. Deshayes is of the same opinion. In his edition of Lamarck, he observes that the *Tellinæ* are allied by almost insensible gradations to the *Psammobiæ* (*Psammobia* and *Psammotea*, Lam. *Psammocola*, De Blainv.) on one side, and to the *Donaces* on the other, not only in the characters of the shells, but in that of the animals. Under *Psammobia*, however, it would appear that his observations on the animal are founded on the figure in Poli, for he says that in a species made known to him by MM. Quoy and Gaimard from the voyage of the Astrolabe, characters were observed which, up to that time, the *Tellinæ* had not offered. The lobes of the mantle of this animal were very thick, dentelated, and reaching beyond the shell, which thus became demi-internal. [PSAMMOBIA.]

Geographical Distribution and Habits.—Found in almost all seas, but more particularly in those of warm climates, where, like the *Donaces*, they live plunged in the sands and sandy mud; *Tellina* having been found in the former at depths varying from the surface of the sea to seventeen fathoms, and *Tellinides* in sandy mud at depths ranging from five to sixteen fathoms. Mr. G. B. Sowerby observes that they are commonly the prey of *Aporrhaides*, *Buccina*, and other carnivorous *Trachelipods*, which pierce the shell to devour the inhabitant.

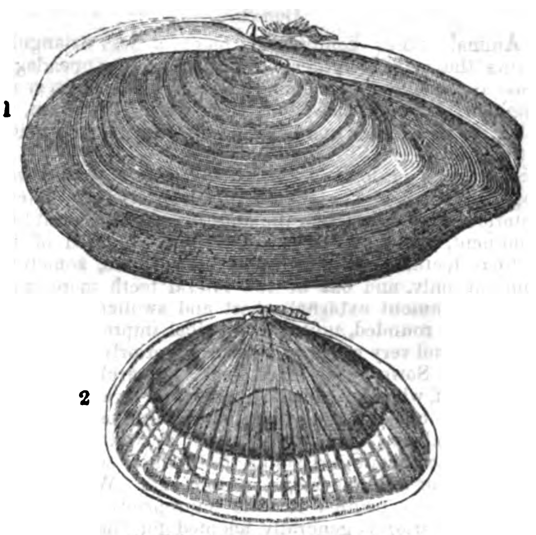
The species are very numerous. M. Deshayes, in his tables, makes the number of living species sixty-eight, and that of *Tellinides*, one. In his edition of Lamarck (1835), he records sixty-two only, the number of species of Tellinides being still one. Of these, he considers some as repetitions or varieties (*Tellina unimaculata*, *Tellina sulphurea*, for example, the first of which he considers a white variety of *T. radiata*, and the second as identical with *T. latirostra*, the only difference being that of colour), and others as founded merely on the difference of age (*T. chloroleuca*, for example).

Lamarck divided the species into the following divisions.

1. Those with the shell transversely oblong. (Ex. *T. radiata.*)
2. Those with the shell orbicular, or rounded oval. (Ex. *T. scobinata.*)

De Blainville divides the genus thus:—

1. Subtriquetral species. (Ex. *T. bimaculata.*)
2. Elongated species, but which have the posterior side shorter and narrower (plus étroit) than the anterior. (Ex. *T. radiata.*)
3. Oval, or suborbicular, and nearly equilateral. (Ex. *T. scobinata.*)
4. Equilateral species, sufficiently elongated, almost without a flexuous fold; two divergent cardinal teeth, and two distant lateral ones, of which the anterior is but little distant from the umbo. (*Tellinides*, Lam.)



[1. Tellina rostrata. 2. Tellinides.]

FOSSIL TELLINIDÆ.

Mr. G. B. Sowerby, in his '*Genera*,' says that the fossil species are not numerous, and only found in the newer tertiary beds. De Blainville gives the number (1825) at twenty-three, of which there are four analogous in the Plaisantin, according to Brocchi, and three identical at Grignon, according to M. Defrance. M. Deshayes, in his tables, makes the number of fossil (tertiary) species fifty-four, and he records twelve species as both living and fossil (tertiary). In his edition of Lamarck (who, at the end of the notice of his fourth and last fossil species, printed in both editions, refers to the seventh volume of the 'Annales du Muséum,' for other fossil Tellens), he gives sixteen.

Among the fossil shells collected from the western borders of the Red Sea, by Mr. James Burton, communicated to Mr. Lyell by Mr. Greenough, then President of the Geological Society, are the following species not noticed in the tables: *Tellinæ Lingua-felis*, *rugosa*, *virgata*, *rostrata*.

The fossil species are recorded as occurring in the Supracretaceous group, in the Cretaceous group, and in the Oolitic group (Coralline Oolite, Yorksh.; Kimmeridge clay; Bernese Jura). Mr. Murchison mentions two species (probably) in the Salopian outlier of Lias.

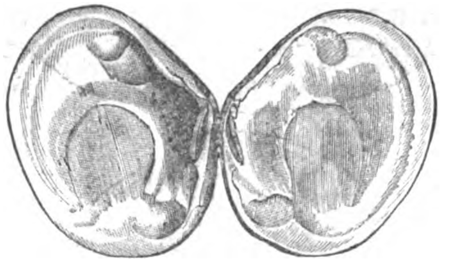
Amphidesma.

Lamarck, after having founded the genus *Donacilla*, thought it necessary to suppress it and unite it to *Amphidesma*. But, observes M. Deshayes in his edition, he did not perceive that many other shells which he placed among the *Mactræ* and *Crassatellæ*, had absolutely the same characters with Donacilla, and differed, generally, from the greater part of the *Amphidesmata*, *Mactræ* and *Crassatellæ*. In consequence of these observations, and from examinations both of shells and of the animal communicated to him by MM. Quoy and Gaimard, M. Deshayes formed his genus *Mesodesma*. We return to *Amphidesma*, reminding the reader that M. Deshayes remarks that it should be studied with attention, that it is 'peu naturel,' and ought not to be retained till it has undergone the necessary reforms. M. Rang, who observes that M. de Blainville had confounded the last named genus with *Lucina*, gives the following characters.

Shell suboval or rounded, of little thickness, longer than it is high, inequilateral, sometimes a little gaping; hinge with one or two cardinal teeth, and sometimes lateral teeth more or less projecting; ligament double; one ligament external and short, the other internal and fixed in a narrow (étroite) hollow of the hinge.

Geographical Distribution, Habits, &c.—As the genus was left by Lamarck, it would appear to be widely spread, for it is recorded as occurring in the European seas (Northern, English channel, Mediterranean); those of New Holland and the south; and on the coasts of Brazil. But it should be remembered that *Amphidesma corbuloïdes*, Lam., *Mya Norwegica*, Chemn., is the example given by Deshayes for his genus *Osteodesma*, while *A. glabrella* (seas of New Holland and Kanguroo isles) is one of his *Mesodesmata*. The species, which are tolerably numerous in their undisturbed state (*Amphidesma*, Lam.), are said to have been found in sands and mud at depths varying from the surface of the sea to forty fathoms. Lamarck gives sixteen species; Mr. G. B. Sowerby has added twelve, brought home by Mr. Cuming. (*Zool. Proc.*)

Example, *Amphidesma variegatum*. Locality, coast of Brazil.



[Amphidesma variegatum.]

Fossil Amphidesmata.

Mr. G. B. Sowerby (*Genera*) says he does not recollect to have seen Amphidesma in a fossil state. Deshayes, in his tables, notes three living species and one fossil (tertiary), probably the new species without a name, recorded by Mr. Lyell, as having been found by the latter at Caltagirone. Five species are recorded by Phillips in the oolitic group. In Dr. Fitton's paper, one species from the green-sand is figured, and described as doubtful.

Mesodesma (Deshayes).

Animal inclining to oval or subtrigonal, flattened; lobes of the mantle united for two-thirds of the posterior length, and provided, at their posterior extremity, with two short siphons prolonged within by a very delicate membrane; foot very much flattened, quadrangular, hidden in part by the branchiæ, which are short, truncated, and fixed (soudées) posteriorly, the external pair smallest and subarticulated. Shell oval, transverse or triangular, thick and ordinarily closed. Hinge with a spoon-shaped hollow, straight and mesial for the ligament, and, on each side, an oblong and simple tooth. (Deshayes.)

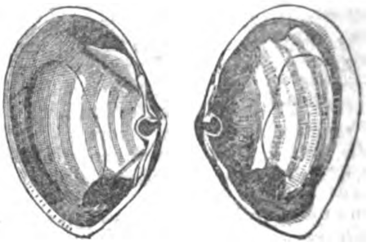
M. Deshayes remarks that the shells of this genus are easily recognized. The shell is always thicker than that of the *Mactræ:* they are more compressed, more completely closed (mieux fermées) and in this respect approach the *Crassatellæ*. The hinge is particularly remarkable; in the middle of the border and immediately below the umbo, is placed a spoon-shaped, triangular, deep hollow, the border of which projects within the valves as in the greater part of the *Lutrariæ*. On each side of this spoon-like process, in which the ligament is inserted, is seen in each valve a large thick tooth, and behind, a hollow to receive the tooth of the opposite valve. Muscular impressions unequal; the anterior largest, elongated; the posterior somewhat rounded. The Pallial impression in the species which approach the *Mactræ* has a moderate posterior sinuosity which diminishes more and more in proportion as the species have more resemblance to the *Crassatellæ*. The sinuosity exists, however, in all the species of the genus.

M. Deshayes concludes, from these and other observations, that the *Mesodesmata* constitute a distinct genus, differing more from the *Amphidesmata* than the *Mactræ* and *Crassatellæ ;* and he purposes to place it in the method between these genera as intermediate, or being the point of junction, serving to confirm the relations established by Lamarck between the *Mactræ* and *Crassatellæ*, relations which, he observes, many zoologists have wished to destroy without sufficient reasons. M. Deshayes then gives a list of ten species which are either *Mactræ*, *Crassatellæ*, *Amphidesmata*, or *Erycinæ* of authors. In his tables only seven species, and those living, are recorded. The genus is there placed between *Mactra* and *Erycina*. No fossils mentioned.

Cumingia (G. B. Sowerby).

'A genus which should be placed near to Amphidesma. It is remarkable for the dissimilarity of the hinge of the two valves, one having a strong lateral tooth on each side of the ligament, and the other being entirely destitute of lateral teeth. Having only met with a small West Indian species, we could not venture to consider this genus as established, until Mr. Cuming showed us several species in his rich collection of South American and Pacific shells, one of which is sufficiently large to show the characters distinctly.' (Genera of Recent and Fossil Shells, No. 40.) Mr. Sowerby characterizes the shell as inequilateral, equivalve, with the anterior side rounded and the posterior rather acuminated. A single small anterior cardinal tooth observable in each valve: one strong lateral tooth on each side of the hinge in one valve, but no lateral tooth in the other valve; ligament internal, and affixed to a somewhat spoon-shaped pit in each valve. Muscular impressions two in each valve, lateral and distant, the anterior irregular and oblong, the posterior rounded. A very large sinus in the muscular impression of the mantle.

Geographical Distribution and Habits.—Tropical seas as far as is yet known, in clay, mud and sand, in the fissures of rocks, at a depth varying from the surface of the sea to six fathoms. No fossil species known. Example, *Cumingia mutica* (Sow.)



[Cumingia mutica.]

Mactra.

Animal oval, somewhat thick, with the borders of the mantle thick and simple, furnished posteriorly with two tubes but little elongated, and united; branchial laminæ small and nearly equal; foot oval, trenchant, very long, angular. Shell transverse, inequilateral, subtrigonal, sometimes a little gaping at the sides; umbones protuberant; hinge with one cardinal tooth, folded into the shape of the letter V, the point being nearest the umbo, and the branches diverging from it; posterior to this and very close to it is a very thin sharp tooth; sometimes the branches of the folding tooth are separated at the base, forming two diverging teeth; ligamental pit immediately behind the angular tooth and projecting within the shell. Lateral teeth, two on each side in one valve, one on each side in the other, diverging from the umbones, and very near the margin, thin, mostly elongated, and the inner ones more prominent than the outer, but in some species very short, in the thicker species perpendicularly striated. Muscular impressions two, lateral, distant; pallial impression with a small sinus. Ligament consisting of two portions (as usual), one, by far the larger, internal; the other external. In some species the umbones are separated, and the ligament forms a deep pit extending both within and without to the point of the beaks: of this *M. Spengleri* is an example. (G. B. Sowerby, principally, for the shell.)

'This genus,' says Mr. G. B. Sowerby, 'contains a great number of species, some of which are handsome and others very singular shells; upon examining a number of species, we think it might be desirable to divide it into several genera, because we find several distinct forms in it.' (Genera.)

Geographical Distribution.—Wide. Europe, East and West Indies, Africa, North America, &c.

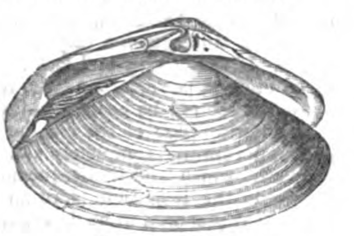
Habits.—Buried generally in sandy mud and sands, at a depth varying from the surface of the sea to 12 fathoms.

The species are numerous; Deshayes, in his tables, gives 32 living: in his edition of Lamarck 33; but, in his opinion, one of these, *M. donacia*, is not a *Mactra* but a *Mesodesma*, and others are repetitions or varieties.

De Blainville thus divides the genus:—

1. Species whose cardinal teeth become nearly non-existent in consequence of the enlargement of the ligamental hollow. (Ex. *M. gigantea*).
2. Species all of whose teeth are very large, lamellar, and not striated. (Ex. *M. stultorum*).
3. Thick and solid species without an epidermis; the lateral teeth finely striated; mantle pierced with two openings, but almost without tubes. (Ex. *M. trigonella*).
4. Very thick solid species striated longitudinally; cardinal teeth none or next to none; lateral teeth very

thick, approximated, raised: an external ligament besides the internal one. (Ex. *M. crassa*).



[Mactra Brasiliana.]

Fossil Mactræ.

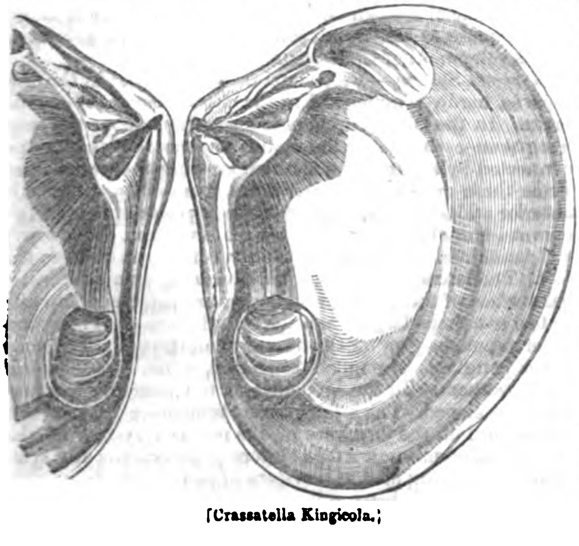
Mr. G. B. Sowerby says, 'The fossil species are not numerous; they are only found in the tertiary beds, unless, indeed, some very singular fossils found in the secondary strata, particularly oolite, be truly referable to this genus; of this, however, we cannot be certain, because we know not their hinges; they will be found represented in Sowerby's Mineral Conchology.' De Blainville quotes M. Defrance for 18 fossil species, one identical, one analogue in the Plaisantin, and another analogue 'dans la Caroline du Nord.' Deshayes, in his tables, gives 14 fossil (tertiary), and four as both living and fossil (tertiary): in his edition of Lamarck, but three species are given as fossil only. Among the fossil shells from the borders of the Red Sea, collected by Mr. J. Burton and communicated by Mr. Greenough to Mr. Lyell, we find *M. stultorum* with a (?) Mr. Lea gives three species, *M. dentata*, *Grayi*, and *pygmæa*, from the Claiborne beds.

Crassatella.

Shell equivalve, transverse, inequilateral, not attached nor gaping. In one valve two strong, cuneiform, rugose, sometimes perpendicularly-grooved cardinal teeth: in the other only one; ligament internal, attached to a concave space placed on the anterior side of the hinge; the pit divided by a carina into two portions, and that part of the ligament attached to the outer portion visible externally when the valves are closed: two strong oblong depressions may then be observed, one on the anterior side of the umbo, rather elongated, and not so distinct as the other on the posterior side. Muscular impressions two, distant, lateral, rather oblong; lateral teeth none, or nearly obsolete. Shell very thick, particularly in old specimens: the recent ones with a brownish somewhat horny epidermis; all more or less transversely grooved near the umbones.

Geographical Distribution.—Seas of New Holland.

M. Deshayes, in his tables, gives the number of living species at nine. In his edition of Lamarck, he makes them eleven, the fifth and the four last of which, he says, belong to his genus *Mesodesma*, and he observes that, by reducing the genus *Crassatella* to those species only which have two cardinal teeth, and, at their sides, the ligamental hollow large and superficial, it will be rendered much more natural than Lamarck left it. Thus the number of known living species would be reduced to seven or eight, and the others, which have the ligamental hollow, mesial and deep, and a cardinal tooth on each side, would, he says, be placed in his genus *Mesodesma*; but these numbers do not agree. The shells of the two genera, he adds, will be distinguished, moreover, by means of the pallial impression, which is always simple in the *Crassatellæ*, and always sinuous posteriorly in *Mesodesma*. Mr. G. B. Sowerby (*Zool. Proc.*) has described two new species brought home by Mr. Cuming.



[Crassatella Kingicola.]

Fossil Crassatellæ.

Mr. G. B. Sowerby, in his '*Genera*,' mentions *C. tumida* and *C. compressa* from the calcaire grossier of the environs of Paris, and *C. sulcata* as very common at Hordwell, and as appearing to be characteristic of the London clay. M. Deshayes remarks upon that shell, that Lamarck regarded the fossils at Beauvais and those living at New Holland as analogues; but that he has satisfied himself that those fossils and *C. sulcata* are different species. *Crassatella tumida*, he observes, approaches *C. Kingicola* nearer than any other.

De Blainville states that there are seven, at least, fossil in France, and that M. Defrance mentions twenty from the lower chalk, with some doubt. In his tables, M. Deshayes gives 24 fossil species (tertiary): in his edition of Lamarck he records 14 only. It appears, in the catalogues, in the supracretaceous and cretaceous groups.

Of the other genera belonging to the *Conchacea*, *Venerupis*, *Petricola*, *Coralliophaga*, and *Clotho*, will be found under title Lithophagidæ*, and the genera separated from *Venus*, or allied to that family, under Veneridæ.

CONCHI'FERA. Lamarck's name for that large class of molluscous animals which are protected by shells consisting of two principal pieces; shells commonly known under the denomination of Bivalves. It comprises the whole of the acephalous mollusks of Cuvier, including the *Brachiopoda*.

Lamarck divided the class into two great orders, the *Dimyaria* (Dimyaires), or conchifers, furnished with two adductor muscles, and the *Monomyaria* (Monomyaires), or conchifers furnished with one adductor muscle only. M. Deshayes would separate the class into three subclasses. 1. The *Polymyaria*, or *Brachiopoda*. 2. The *Dimyaria*. 3. The *Monomyaria*. He founds this order of arrangement on the principle that the organization of the Brachiopoda is more simple than that of the other conchifers, while that of the *Dimyaria* is somewhat less complex than that of the *Monomyaria*.

Organization.

Digestive System.—*Mouth*, without any hard parts, situated anteriorly: in the Dimyarians concealed between the foot and the anterior retractor muscle: in the Monomyarians under a sort of hood made by the mantle. Labial palps or lips flattened, sometimes truncated, sometimes laminated internally, more or less elongated, extending on either side. No salivary gland. *Œsophagus* varying in length and capacity; often wanting altogether both in Dimyarians and Monomyarians. *Stomach* sometimes, not often, lengthened and narrow, sometimes subcircular, generally pear-shaped; interior surface with irregular depressions, or biliary crypts. *Intestine* arising posteriorly, convoluted within the liver and ovary, and so brought towards the back and mesial line of the animal, and continued posteriorly to the vent, nearly of the same diameter all through. *Rectum*, which commences with the dorsal part of the intestine, shorter in the Monomyarians than in the Dimyarians: in the former it is convoluted behind the single central adductor, and terminates in a floating vent between the edges of the mantle; in the latter the vent is situated above the superior adductor. *Liver* very large, supported by muscular fibres, which traverse it, pouring the bile into the stomach by the biliary crypts.

Absorbent System.—Generally agreed to be non-existent, the veins performing the office of absorbing vessels.

Circulatory and Respiratory System.—*Circulation*, a simple circuit, of two vascular systems, viz., a ventricle and an arterial system,—a venous system and two auricles, the ventricle firmly and closely embracing the rectum, so that it *appears* to pass through it. The arterial system not complicated, the venous system upon a considerable scale of development. (Poli, *Testacea utriusque Siciliæ*.) *Circulating fluid* nearly colourless, or white, scarcely tinged with bluish, slightly viscid, and with very little *crassamentum*. [Blood, vol. v., p. 4.] 'Circulation then is an extremely simple function in the conchiferous mollusks: an aortic ventricle gives the blood impulse enough to carry it through the two systems of vessels, to expel it from the heart, and to bring it back again to the auricle. In other branchiferous animals, the auricle is sometimes adapted to give the blood a new impulse when it is about to pass through the branchiæ; here, on the contrary, the auricles do not receive the blood until it has been exposed to the revivifying influence of the organs of respiration.' (Deshayes.) *Respiration.*—By means of branchiæ variously disposed, as will be noticed in the different families.

---

* Perhaps, also, Ungulina; M. Rang having of late made observations confirmatory of its perforating habits.

Generative System.—Simply an ovary enveloped in the visceral mass. Taking the common oyster for example, it rests, a whitish mass of considerable size, upon the adductor, and may be seen through the mantle. It occupies the whole upper part of the mollusk, and creeps down along the sides and lower parts, being filled at the time of reproduction with a milky fluid, containing multitudes of small granules of a whitish colour. These are the eggs; and, in many of the family, they are not, at the time of their exclusion, abandoned at once, but are deposited between the two membranes of the branchial laminæ, where they undergo a kind of incubation. In some the shell is developed in the ovum before it quits this receptacle. This fostering of the eggs seems to be analogous to the gestation of the eggs in the crustacea and the pipe-fishes. Sir Anthony Carlisle (*Hunterian Oration*, 1826) says, 'Oysters are viviparous, and their young are found within the tracheal passages, and between the folds of the coverlet (mantle) during the months of June and July in this climate. In its first state, the oyster exhibits two semiorbicular films of transparent shell, which are continually opening and closing at regular intervals. The whole brood are associated together, by being involved in a viscid slime, and in that state called the *spat*, it being common among viviparous animals of this kind to have their spawn posited in contact with the lungs; the involving slime serves as the first nutriment: and, we may infer, that the fœtal food so influenced by the gills, is at the same time a respiratory supply to the imperfectly formed young.' In the siphoniferous branch of the family, the longer the siphons the larger, as a general rule, is the mass of the ovary: in those forms which have the siphons short, and the foot comparatively large, the ovary is comparatively small. As far as anatomy has hitherto detected this part of the organization, here we have hermaphroditism in the true sense of the word. The whole business of reproduction is apparently carried on within the two valves of the shell without the aid of a second individual, as it is in a hermaphrodite flower. But it will occur to most observers that the conchifera are gregarious; the fixed conchifers (oysters, spondyli, chamæ, &c., for instance) eminently so; and it is by no means clear that this congregation may not be a necessary condition for the fecundation of the ova; and that there may not be a mutual diffusion of some influence analogous to that of the milt in fishes. M. Prevost, who made his experiments upon the *Uniones*, would make it appear that though there can be no coitus, still no propagation takes place without an assemblage of these animals upon the same spot.

Muscular System, as it regards motion.—Twofold; valvular and locomotive. The first consists in the adaptation of muscular fibre to the movement of the valves, and indeed this muscular apparatus may in some cases be made ancillary to locomotion, as in the Pectens, for example. These adductor muscles are attached to opposite points in each valve, and their office is to close the valves by their contractility, or suffer them to expand by their relaxation. In the greater number (Dimyaria) there are two: one anterior near the oval aperture, the other posterior. The Monomyaria have *apparently* one only; but Poli has shown that this muscle is in reality an approximation of two, and thence most probably arose the slight regard manifested by Cuvier for the division of Lamarck. The second or true locomotive organ is called the foot, and is formed of various layers of fibres, which, by their counteraction, bestow on it great power of motion, when the organ is well developed. Though in some species merely rudimentary, it is found in all the Dimyaria—not so in the Monomyaria, some of which are entirely without it. Its place may be defined by stating that the mouth is generally hidden between its base and the anterior adductor. Where well developed it is of various shapes, cylindrical, flattened, &c. In some it is a digging organ, or kind of ploughshare for making a furrow in the sand or mud wherein the animal means to lie hid; in others, as in the cockle, &c., it becomes a leaping organ, and enables the conchifer to clear a boat's gunwale when laid on the bottom boards. The foot is the instrument which produces the Byssus. Under that title De Blainville's theory will be found. Deshayes has since given a very different account of the structure:—'If the byssus and foot of a byssiferous mollusk be placed under a powerful lens, the last filaments of the byssus are first seen to be nearest to the base of the foot; and, if the inferior edge of the foot be inspected, a fissure will be found running completely along it, at the bottom of which a brownish and semicorneous filament is often to be perceived: this is neither more nor less than a filament of the byssus prepared to be detached by the animal, in order to which the animal stretches forth its foot until it encounters the object upon which the other fibres of the byssus are fixed; to this it applies the point of the foot, which then secretes a small quantity of glutinous matter, continuous with the silky filament lying along the bottom of the furrow of which we have spoken. When the pasty matter has acquired sufficient consistency, and is firmly fixed to the stone or other body at the bottom, the animal retracts its foot, and in doing so detaches the new fibre at the base of the pedicle. The mode in which the filaments of the byssus are formed is consequently entirely different from that in which hair or the horns of the higher animals are evolved, and it is easily understood when the intimate structure of the foot of the byssiferous mollusks is known, when we are aware that this organ consists in its centre of a pretty considerable fasciculus of parallel and longitudinal fibres. By a faculty peculiar to the class of animals that now engages our attention, the fibres situated at the bottom of the groove of the foot become horny, and are detached in succession in the form of threads as they become consolidated.'

The siphons are retracted by means of two lateral fan-shaped muscles, situated posteriorly.

Mantle and Cuticular System.—Two thin fleshy laminæ applied over the back of the animal, extending over its sides, and with its edges meeting along the anterior middle aspect of the body, covering, or closely in contact with, the whole interior surface of the shell, form the mantle, in the thickened edge of which is the principal apparatus that secretes the shell: there are also frequently rows of contractile tentacular cilia fringing it. The whole of these parts are exquisitely sensible, and highly contractile. The mantle becomes free at the origin of the branchiæ, and forms a cavity round the lower part of the animal, containing the visceral mass, the foot, for the extrusion of which there is an opening, and the branchiæ. This is the pallial sac, and is the area wherein the currents for respiration and nutrition are formed. The siphons, where they exist, project from the mantle, with which they are continuous. They are sometimes very long, and sometimes reduced to mere perforations; sometimes separate, and sometimes conjoined; but in any case the superior siphon is that destined for dejections, and is called the anal siphon, while the office of the lower one is to conduct the water to the branchiæ, whence it is termed the branchial siphon. The structure of these posterior siphons or tubes is eminently contractile, and their apertures are fringed with a number of papillæ of great sensibility, capable of giving notice of the contact of any prejudicial foreign body. The retractor muscle is generally more or less developed, according to the greater or less development of these parts.

Nervous System.—Very simple. Symmetrical in the *Dimyaria*, hardly symmetrical in the *Monomyaria*. No true brain. In the Dimyaria there is a ganglion above the œsophagus on each side of the mouth towards the labial palps, connected by a transverse filament crossing the œsophagus. From these ganglions filaments are given off to the mouth, anterior adductor, &c.; and, from their posterior edges, two nervous branches go to the stomach, liver and heart, ovary and branchiæ. A branch of some volume goes down to the foot. The lateral filaments, after advancing along the internal surface of the posterior adductor, are conjoined into one or two ganglions larger than the anterior ones. These posterior ganglions give off the nerves to all the posterior parts: if the ganglions are much separated, a nervous filament connects them. In the Monomyaria the system is less perfectly developed. The student must remember that though we owe to Poli the discovery of the nervous system of the conchifers, he mistook it for a system of absorbents and lymphatics, speaking of it as a system of lacteal vessels.

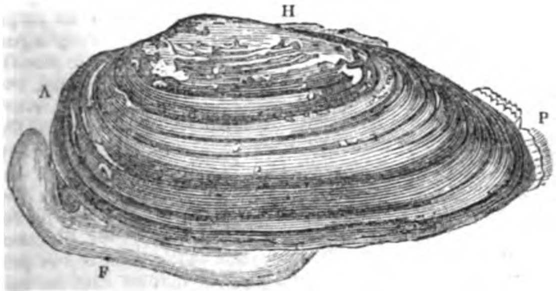
The *senses* of these animals must, reasoning from this part of their organization, be very confined; and indeed there is no good ground for attributing to the generality of them anything beyond a sense of touch and taste. That most of them may be conscious of the presence or absence of light is possible. 'Not having any especial organs for seeing, hearing, or smelling,' says Sir Anthony Carlisle, speaking of the common oyster in his Hunterian Oration (1826), 'the creature is limited to perceive no other impressions but those of immediate contact; and yet every part of its exterior seems to be sensible to light, sounds, odours, and liquid stimulants. It is asserted by fishermen, that oysters, in confined beds, may be seen, if the water is clear, to close their shells whenever the shadow of a boat passes over them.'

M. Deshayes goes so far as to say that no especial organ of sense can be detected among them, unless, perhaps, those of touch and taste; but we must not forget what have been called the eye-specks in the Pecten, to the animal of which Poli gave the name of Argus, from the supposed number of its visual organs. The pectens are free swimmers, and, from their rapid and desultory motions, we have heard them termed the butterflies of the ocean. The manner in which these motions are executed, especially on the approach of danger, indicates the possession of a sense analogous, at least, to that of ordinary vision. These eyespecks may be seen in the pecten placed at short intervals round the thickened edge of the mantle, on the outworks, as it were, of the internal part of the animal fabric. 'As locomotion so vision' is a general aphorism, not without its particular exception; for there is good reason for believing that *Spondylus*, which is a fixture in its adult state, is furnished with these visual specks.

Shell.—The lobes of the mantle, the thick edges of which form the principal secreting organ, determine, apparently, the form of the shell. The general structure of this substance will be given elsewhere. [Shell, Pearl.] At present it will only be necessary to state that the shell of the *conchifera* is bivalve, or composed of two pieces, often covered with an epidermis, joined at their upper edge (corresponding to the dorsal part of the animal) by a *hinge*.

The hinge is entirely formed by the inner layer of shell, and consists of either a simple cardinal process, or a serrated edge, or of projections, or teeth as they are called, and corresponding cavities into which they are inserted. To this hinge is superadded a ligament, which binds the two parts together and keeps the parts composing the hinge in their places. The ligament is either internal or external, internal when it is hidden by the outside of the cardinal edge, external when it appears beyond it, and is highly elastic, being composed of a number of fibres parallel to each other and perpendicular to the valves which they connect. This is a beautiful contrivance for the necessities of the animal. When undisturbed, the elastic ligament keeps the valves open, and the animal functions are carried on without any effort; when danger is apprehended, or circumstances require it, the adductor muscle or muscles contract, overcome the resistance of the hinge, and shut the valves close till they may be opened in safety. One of the earliest signs of the loss of vitality in the conchifers is the more than ordinary wide gaping of the shell. This arises from the state of the adductor muscle, which being relaxed by death is no longer an antagonist to the elastic ligament.

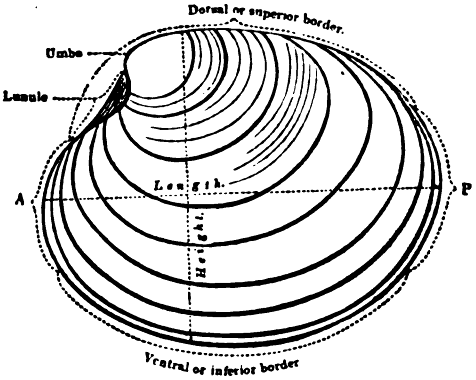
[Cyclas cornea.]



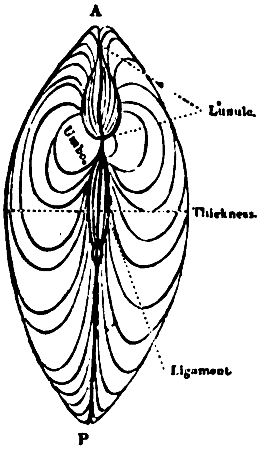
[Unio pictorum.]

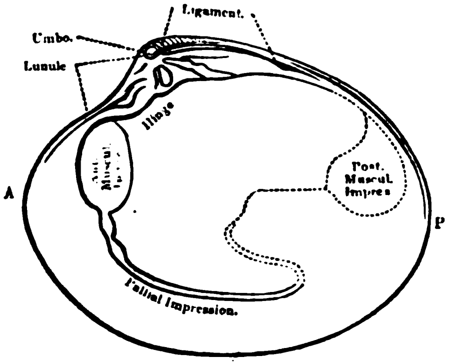
A. Anterior, or oral extremity. P. Posterior, or anal extremity, with the siphons or tubes. H. Hinge. F. Foot.

The common oyster will serve as an example of the Monomyarians, and the cuts will give a general idea of the Dimyarians, their shell, and its muscular impressions.



A. Anterior, or oral extremity.
P. Posterior, or anal extremity.





[Shell of Cytheræa.]

The student should more especially consult the works of Poli, Cuvier, Lamarck, De Blainville, Rang, and Deshayes. The last-named author has lately proposed an amended arrangement, which will be found at the end of his article "Conchifera," in the Encyclopædia of Anatomy and Physiology *.

CONCHOID, (κογχοειδής, resembling a shell.) This name was given by Nicomedes (in the second century) to a curve, by which he proposed the finding of two mean proportionals, and the duplication of the cube. It is found in the commentary of Eutocius on the sphere and cylinder of Archimedes, and in the fourth book of Pappus.

This curve is described by a revolving line, which passes through a fixed point, and is always produced to meet a certain fixed line. On the revolving line, from the point in which it meets the fixed line, set off a given line both ways. The two points thus laid down trace out the upper and lower conchoid, two different branches of the same curve. The lower conchoid has two points of contrary flexure, a cusp, or a loop, according as the given line is less than equal to, or greater than the perpendicular from the pivot of revolution to the fixed line. Taking the pivot of revolution as the origin, and the perpendicular just named as the axis of x, the equation of the conchoid is,

---

* In the article 'Conchacea,' p. 497, under the cut in the first column, for 'Cardium lævigatum,' read 'Cardium elongatum.'

$$(x^2 + y^2)(x - b)^2 = a^2 x^2.$$

where a is the given line, and b the distance of the pivot from the fixed line. [Duplication of the Cube: Trisection of the Angle.]

CONCHO'LEPAS. [Entomostomata.]

CONCHOLOGY, Conchyliologie of the French. The science which teaches the arrangement of the shells of the testaceous mollusks into classes, sub-classes, families, subfamilies, genera, and species. Formerly the great bulk of conchologists, as they were by courtesy called, consisted of mere collectors, who looked upon these beautiful and in many instances richly-coloured forms, as mere luxuries for the eye, mere toys to decorate a cabinet, much after the fashion of old china. But of late years this science has assumed its proper rank, and is justly considered as holding a high place, whether considered zoologically or geologically. To the geologist it has become a power of the greatest value in indicating the difference of strata and their comparative ages; while Linnæus, Poli, Cuvier, Lamarck, and a host of other philosophers, both dead and living, have shown its high zoological importance. We could not pass the title altogether unnoticed, but we must dismiss it for the present. It is, in our opinion, necessary in the existing state of our knowledge, that the student should consider *shells* as what they really are, *skeletons of molluscous animals*, forming a principal ingredient in their organization with which they are intimately blended, and not mere insulated bodies, mere stones as we have heard them termed, unconnected with the soft parts of the animals. For these reasons the reader will find the general view of this subject under the title Malacology.

CONCINNOUS INTERVALS, in Music, are the various concords. [Concords.]

CONCLAVE (a Latin word, which signifies a private room), is the name given to the assembly of cardinals when they meet for the purpose of electing a pope. [Cardinal.] The day following the last of the funeral of the late pope, the cardinals, after hearing a solemn mass de Spiritu Sancto, proceed to one of the pontifical palaces, generally the Vatican, where rooms have been prepared for each of them, and where they remain shut up till the election has taken place. The keys of the palace are left in the care of a prelate, chosen previously by the cardinals, and who is styled governor of the conclave. Each cardinal has with him a secretary, called conclavista, and two domestics. They meet once a day in the chapel of the palace, where a scrutiny is made of their votes, which are written and placed in an urn: this is repeated every day till two-thirds at least of the votes are in favour of one candidate for the pontifical chair, who is then considered as duly elected. Each cardinal in giving his written vote accompanies it by his name, written in a separate sealed paper, which is not opened till the pope is elected, when the names of the voters are made known. When the election is strongly contested, and the cardinals grow weary of being shut up in conclave, negotiations in writing are carried on between the leaders, and a compromise is entered into by which two or more parties, not being able singly to carry the election of the irrespective candidates, join in favour of a third person, who is acceptable to them all, or at least not obnoxious to any of them. This often gives an unexpected turn to the election. During the conclave the ambassadors of Austria, France, and Spain, have a right to put their veto each upon one particular cardinal, whose election would not be acceptable to their respective courts. The new pope being elected, and his assent being given, he proceeds to dress himself in his pontifical robes; after which he gives his blessing to the cardinals, who give him the osculum pacis (kiss of peace). After this the name of the new pontiff is proclaimed to the people from the great balcony of the palace, and the castle Sant' Angelo fires a salute, and all the bells of the city of Rome ring a merry peal for one hour. (Calindri, *Saggio Geografico Statistico dello Stato Pontificio*, 1832.)

Regulations for the conclave, and the mode of election, have been issued by several popes, beginning from Nicholas II., in the council of Lateran, A.D. 1059, down to Gregory XV., by his bull of 1621, and Urban VIII. in 1625. In times of war or civil disturbance the conclave has been held in other places besides Rome; that in which Pius VII. was elected was held at Venice. Accounts of particular conclaves have been given by numerous writers who have treated of the history of the popes. (Meuschen, *Cæremoniale Electionis et Coronationis Pontificum Romanorum*, Frankfort, 1732.)

CONCORD, in Music, two combined sounds which are universally agreeable to the ear. It is commonly held, that the more frequently the vibrations of two strings coincide, and—which amounts to the same thing—the lower the terms in which the proportions of vibrations are expressed, the more pleasing the concord: but the 4th, an interval much less agreeable than either the 3rd or 6th, is a formidable exception to those rules, proving their fallibility by the test of experience. Rousseau is of opinion—and we agree with him—that the pleasure afforded by concords is attributable to their source, namely, the perfect chord [Chord], which is itself the product, or combination, of nature. This, and its inversions, furnish us with all the concords.

Concords are the 8th (or octave), 5th, 3rd, and 6th. Their ratios are, 2 : 1, 3 : 2, 5 : 4, 5 : 3. The two first are called *perfect*, because, as concords, not liable to any alteration by sharps or flats. The two last are called *imperfect*, because alterable.

The 4th has always proved a stumbling-block to writers on harmony, for the reason above alluded to; but as a component part of an inversion of the perfect chord, it has some claim to be admitted among the concords. A great and recognised authority, of the modern French school, says, that it is treated as a discord in relation to the bass, as a concord in relation to the middle and upper parts. M. Catel, however, has not in this instance proved as correct as usual. except in the chords of $^{4}_{2}$ and $^{6}_{4}$, the 4th, as an inner part, is, and can only be, treated as a discord.

CONCORDANCE, 'a book which shows in how many texts of Scripture any word occurs.' (Dr. Johnson). More particularly, it is a dictionary or index of all the important words in the Bible, alphabetically arranged for the purpose of finding passages and of comparing the various significations of words. To critical interpreters this class of books is justly considered of the greatest utility, as furnishing an instrument by which the determination of the meaning of obscure expressions may be greatly facilitated by reference to all the parallel passages. 'A good concordance,' says Dr. Geddes (Prospectus, p. 71), 'is undoubtedly the best means of understanding the Hebrew Scriptures.' While the Bible remained in manuscript, and was not divided into chapters and verses, indices of the words and phrases could neither be formed nor used; but as soon as these divisions began to be made, the great importance of concordances, or alphabetical indices, was at once perceived, and several learned men employed much time and labour in constructing them. The compiler of the first concordance in any language was Hugo de St. Caro, or Cardinal Hugo, who died in 1262. The earliest concordance of the Hebrew text is by Rabbi Mordecai Nathan, printed at Venice in 1523. Its Hebrew title is, 'The Light of the Way.' It contains all the Hebrew roots, branched into their various significations, and is said to be the produce of ten years of incessant labour. A more correct edition was published at Basil in 1581, and a Latin translation by Reuchlin in 1556; but both the Latin and the Hebrew editions are extremely inaccurate. The errors are, for the most part, corrected in the work by Calasius, which combines the labours of Nathan and Reuchlin. It is entitled 'Concordantiæ Sacr. Bibliorum Hebr. et Lat.,' 4 tom. fol. 1621. The additions by Calasius consist of very learned and laborious etymological remarks. The reprint of this ponderous work in London in 1747-9 contains among its subscribers all the crowned heads of Europe, including the Pope. The work by the elder Buxtorf, 'Concordantiæ Bibliorum Ebraicæ nova et artificiosa methodo dispositæ,' &c., fol. 1632, is more correct than Nathan's; but the references are made by Hebrew letters, and to the Rabbinical divisions of the Old Testament. An abridgment of it, by Ravius, is entitled, 'Fons Zionis, sive Concordantiæ Hebr. et Chald.,' 8vo. 1677. Dr. John Taylor, under the patronage of the English and Irish bishops, published, in 2 vols. fol. 1754, 'A Hebrew Concordance, after the manner of Buxtorf, adapted to the

English Bible. It is a complete and useful book for the English scholar. The 'Concordantiæ Particularum Ebræo-Chaldaicarum,' fol. 1675, and 4to. 1679, by Noldius, Theological Professor at Copenhagen, is very valuable for the explication of passages dependent on the Hebrew particles, a comparison of which is made with the Greek. The best edition is that of Jena, in 4to. 1734, with a Lexicon of Particles, by Michaelis, extremely useful to the Hebrew critic.

With respect to concordances of the Greek Septuagint, we may notice especially, Kircheri 'Concord. Vet. Test. Græcæ, Ebræis vocibus respondentes,' 2 tom. 4to. 1607; but the Hebrew being placed first, it is more useful for consulting the Hebrew than the Greek text. The most complete and accurate work of this description is Trommii 'Concord. Græcis Versionis dictæ LXX.' 2 tom. fol. 1718. 'I wish,' says Michaelis, 'this Concordance were in the hands of every theologian.' It contains Heb. et Chald. Indices; but the book of Daniel is omitted, the Septuagint version of it being at that time unknown.

The most important concordances of the Greek New Testament are, Betuleii 'Concord. Græcæ Nov. Test.,' fol. 1546. This is the first which appeared: it is now extremely scarce. 'Concord. Græco-Latinæ Nov. Test. ab Hen. Stephano Concinnatæ,' fol. 1594, 2nd ed. 1624, is a work unworthy of so distinguished a man, on account of its great inaccuracy. Schmidii 'Nov. Test. Græci *ταμιεῖον*,' fol. 1638, revised ed. 1717 at Gotha, was beautifully reprinted in 2 vols. 8vo. at Glasgow, 1819. It is much more correct and valuable than that by Stephens. The 'Lexicon Anglo-Græco-Lat. Nov. Test.,' by Andrew Symson, fol. 1658, is a work of prodigious labour, but rendered almost useless by its bad arrangement. The 'Concordance to the Greek New Testament,' with the English to each word, by Dr. Williams, 4to. 1767, is sufficiently complete for ordinary purposes. The first concordance to the Latin Vulgate is that by Cardinal Hugo, entitled, 'Concord. Bibliorum et Canonum,' fol. 1479. After the revision of the Vulgate by Pope Sixtus V., a new and amended edition of Hugo's work appeared at Antwerp in 1617, and subsequently at Geneva in 1625, and at Paris in 1683. There have since been a great number of reprints. The best is that of Avignon, 2 vols. fol. 1786. In compiling the original MS. it is said that the cardinal engaged the services of 500 Dominican monks.

The first Concordance to the English New Testament was 'imprinted by Thomas Gybson' previous to the year 1540. The first to the entire Bible is by 'Jhon Marbeck,' London, in folio, 1550. Subsequent to these there have been several, the principal of which are, Knight's 'Concordance Axiomatical,' fol. 1610; Cotton's Concordance, fol. 1618; Newman's large and complete Concordance, fol. 1643; Bernard's 'Thesaurus Biblicus,' fol. 1644; Wilkins's Concordance, 4to. 1647; Powell's, 8vo. 1671; the 'Cambridge Concordance,' fol. 1689; Butterworth's, 8vo. 1767. But by far the most complete and valuable is the one by Alexander Cruden, the merits of which are too well known to require any remark. The first edition was in 4to. 1737; but the most correct is that of 1810. An 8vo. edition, beautifully printed, appeared in 1824. We must notice finally the 'Concordance of Parallels,' by the Rev. C. Crutwell, 4to. 1790. It is a work of great value, compiled with immense labour from a multitude of Bibles and Commentaries in the Hebrew, Latin, French, Spanish, and other languages. For further details respecting the Concordances here mentioned, and several others, see Watt's *Bibliotheca Britannica* and Orme's *Bibliotheca Biblica.*

CONCORDAT is the name given to a formal agreement between the see of Rome and any foreign government, by which the ecclesiastical discipline of the Catholic clergy and the management of the churches and benefices within the territory of that government are regulated. It is, in fact, a diplomatic negotiation and treaty concerning ecclesiastical affairs, including also temporalities belonging to the church. The frequent disputes between the popes and the various states of Europe touching the right of appointing to vacant sees and benefices [BENEFICES], and also about the claims of the see of Rome to part, or in some cases the whole of the revenues of vacant sees and livings, and of the first fruits and tenths of those which it had filled, as well as the immunities claimed in various times and countries by the clergy and supported by Rome, such as exemption from taxation, and from the jurisdiction of the secular courts, the right of asylum for criminals in the churches, and other similar claims, the particulars of which are found in the history of every country of Europe;—all these have given occasion to concordats between the popes and particular states, in order to define the rights of each party, to draw a line between the secular and ecclesiastical jurisdictions, and thus put an end to controversy and scandal. By the concordat of 1516 between Leo X. and Francis I., the king abolished the right exercised by the chapters of electing the respective bishops, a right assured to them by St. Louis and by the states of the kingdom under Charles VII. in 1438. The parliament refused for two years to register this concordat, as contrary to the spirit of the general councils and the liberties of the Gallican church; it registered it at last March 19, 1518, 'by express and repeated commands of the king.' (Gregoire, *Essai Historique sur les Libertés de l'Eglise Gallicane.*) Concordats have become most frequent since the middle of the eighteenth century, an epoch from which the European governments have made themselves more independent of the ecclesiastical power, and the popes have been for the most part men of an enlightened and conciliatory spirit. Benedict XIV., by a concordat with the king of Sardinia, in 1741, gave up to the latter the right of nomination to benefices in various provinces of the Sardinian monarchy, which the see of Rome had claimed till then, as well as the temporalities of the same during a vacancy. A concordat was made between the pope and Charles, king of Naples, about the same time, by which the property of the clergy became subject to taxation, and the episcopal jurisdiction in temporal matters was greatly limited. By another concordat between Clement XIV. and the king of Sardinia, the right of asylum to criminals in the churches was much restricted, and full power was given to the respective bishops to expel and give up to the secular power those guilty of heinous offences. But the most celebrated concordat is that agreed upon between Cardinal Consalvi, in the name of Pius VII., and the first consul Bonaparte, in July, 1801. By it the head of the state had the nomination to the vacant sees, but the pope was to confer canonical institution, and the bishops had the appointment to the parishes and their respective dioceses, subject however to the approbation of the government. The clergy became subject, in temporal matters, to the civil power, just like laymen. All immunities, ecclesiastical courts, and jurisdictions, were abolished, and even the regulations of the public worship and religious ceremonies, and the pastoral addresses of the clergy, were placed under the control of the secular authorities. Most of these provisions remain in force in France to the present day. Regulations nearly similar exist in Austria and other German states. Other concordats have been made with some of the Italian states. By that of 1818 with Naples, the king proposes the bishops, subject to the pope's scrutiny, and the pope consecrates them; the bishops have the right of censorship over the press, and the ecclesiastical courts are re-established for matters of discipline and for ecclesiastical causes as defined by the council of Trent. Appeals to Rome are allowed. It appears from the above facts, that the ecclesiastical authority and influence in Roman Catholic countries vary considerably according to the concordats, if there be any, entered into with Rome, or according to the civil regulations adopted and enforced by the respective governments towards the clergy as towards laymen.

CONCRETE, *concrétum*, in philology and metaphysics, is an epithet applied to the conception or expression of a quality which refers to or implies some particular subject in which the quality exists. It is used to denote a term having a naturally implied union with a subject; in other words, it signifies a quality accompanied with its particular subject, without any mental separation or abstraction, as learned, long, wise, round. It is therefore directly opposed to *abstract*, which denotes a quality conceived generally and separately, without reference to any object to which it belongs, as learning, length, wisdom, roundness. Thus the names of classes are abstract, and the names of individuals concrete; and from concrete adjectives are made abstract substantives. (Dr. Watts's *Logic;* Dr. Johnson's *English Gramm.*) Concrete numbers are subject to the same explanation, being such as indicate or directly imply a subject; as two men, five shillings, in contradistinction to abstract numbers, which denote a conception simply of the aggregate of two or five units. Concrete terms, in the scholastic phraseology, are called *paronyma*. The following remark is from Locke's Essay (b. 3, c. 8, sec. i.)—'This distinction of names shows us the difference of our ideas; for if we observe them, we shall find that our simple ideas have all abstract as well as concrete names, the one a substantive, the other an adjective, as whiteness, white, sweetness, sweet.'

CONCUBINAGE is the cohabitation of a man with a woman, to whom he is not united by marriage. Among the Romans, concubinage was in use before the time of the Emperor Augustus, yet without being formally permitted by law. Augustus, with the view of preventing celibacy and encouraging marriage, A.D. 10, caused the famous law called Lex Julia and Papia Poppæa to be passed, which may be considered as much an ordinance of moral police as a measure in favour of population. This law contained several conditions advantageous for those who had the greatest number of children. By the same law, concubinage was legally allowed to unmarried men, with the restriction that not more than one concubine could be taken, and she must be a woman with whom marriage was not permitted, as women of mean descent, freedwomen, &c. The concubine did not enjoy the same rights as a wife, and the children begotten in concubinage were not considered as legitimate, but were called natural (naturales), a distinction which was of importance as to the right of succession.

Concubinage being inconsistent with the principles of Christianity, the Emperor Constantine the Great enacted laws against the institution, and it is now in all countries considered unlawful. Yet in Germany, among the reigning families, a left-handed marriage (Trauung an die linke hand or morganatische ehe) still sometimes occurs. This kind of marriage resembles the Roman concubinage, as well in its conditions as its consequences.

CONCUSSION of the BRAIN, SPINE, &c. [Head, Injuries of the.]

CONDAMINE. [La Condamine.]

CONDE′, a town in France in the department of Nord, at the junction of the little river Haine with the Scheldt or Escaut, 124 miles in a direct line N.N.E. of Paris, or 132 miles by the road through Senlis, Peronne, Cambray, and Valenciennes: in 50° 28′ N. lat., and 3° 35′ E. long.

Condé, after passing through other hands, came, about the close of the fifteenth century, into the possession of one of the branches of the house of Bourbon, which took from it the title of Prince of Condé. It was taken from the French by Charles V.: it was besieged and taken three times by the French, the last time, in 1676, by Louis XIV., to whom it was ceded at the peace of Nimeguen, A.D. 1678. In 1793 it was taken by the Austrians, and a few weeks after retaken by the French. It is now a place of war of the first class, and one of the bulwarks of the northern frontier. During the French revolution it bore the name of Nord Libre. The streets are irregular: there are only two or three *places* or open spaces, and those small.

The population in 1832 amounted to 3498 for the town, or 5350 for the whole commune. There are some coal-pits in the neighbourhood, and the situation of the place on the Escaut enables the townsmen to carry on considerable trade.

CONDE′-SUR-NOIREAU, a town in the department of Calvados in France, on the little river Noireau, a feeder of the Orne, and on a cross road leading from Mayenne by Domfront to Caen. It is 128 miles west of Paris in a straight line; in 48° 51′ N. lat., and 0° 34′ W. long.

Of the town itself, situated in a valley, the soil of which is far from productive, our authorities give no description: it had, according to Expilly, two parish churches and an hospital in the middle of the last century. The population in 1832 was 4904 for the town, or 5562 for the whole commune. They are engaged in the manufacture of linsey-woolsey, drugget, and cotton goods. Nails also of various sizes and qualities are made, especially for the ship-builders of St. Malo and Granville.

CONDE′, LOUIS II. DE BOURBON, PRINCE DE, born at Paris in 1621, was the son of Henri II. de Bourbon, and grandson of Henri I. of the same name, who, with his cousin Henri of Navarre (afterwards Henri IV.), figured in the civil and religious wars of France, under the reigns of Charles IX. and Henri III. [Henri IV.] The house of Condé was a branch of the house of Bourbon. The town of Condé, in Hainaut, from which it took its title, came to the house of Bourbon in 1487 by the marriage of Francis of Bourbon, Count of Vendôme, with Mary of Luxembourg, heiress of St. Paul, Soissons, Enguien and Condé. Charles de Bourbon, the son of Francis, had many children; the eldest, Antoine, became king of Navarre by marrying Jeanne d'Albret, by whom he had Henri IV.: Louis de Bourbon, another son of Charles, and the first who assumed the title of prince of Condé, was killed at the battle of Jarnac, 1569. [Coligny]. He had married Eléonore de Roye, Dame de Conty or Conti, by whom he had Henri I. of Bourbon, prince of Condé above mentioned, and François, who took the title of prince of Conti.

Louis II., prince of Condé, the subject of the present article, has been styled the Great on account of his military abilities and great success. At the age of 22 he won the battle of Rocroi in Flanders, 1643, against a superior Spanish force. He afterwards fought against the troops of the emperor, and gained the battles of Fribourg and Nordlingen. In 1647 he was sent into Catalonia. In the following year he returned into Flanders and defeated the imperial army commanded by the Archduke Leopold, brother to the Emperor Ferdinand III., at Lens in the Artois. Meantime the civil war of the Fronde broke out at Paris; Condé was courted by both parties, and he served both in succession. He was the means of bringing back young Louis XIV., the queen mother, and Cardinal Mazarin, into Paris in August, 1649. Condé, however, put a high value on his services: he was haughty and warm-tempered, and the cardinal was jealous and suspicious. The result was, that after several vile court intrigues, and plots and counterplots, Condé was arrested by order of the queen and the cardinal, and kept in prison for about one year, when the Parliament of Paris at last obtained his deliverance. Being appointed governor of Guienne, he treated with Spain, and soon after raised the standard of revolt, ostensibly against the cardinal, who continued to exercise the whole political power of the state in spite of the general dissatisfaction. Condé marched upon Paris; engaged Turenne in the faubourg St. Antoine, and entered Paris, where he had the parliament in his favour. The cardinal having at last consented to quit the court, the king published an amnesty, and re-entered Paris, 1652; but the prince of Condé retired to Flanders, where he served for several years in the Spanish armies. He fought, in 1654, at Arras against Turenne, who obliged him to retire, but the retreat was effected with great skill. In 1656 Condé, with Don Juan of Austria, defeated the Marshal de la Ferté, and obliged Turenne to retire from before Valenciennes. In 1658 Condé was defeated by Turenne near Dunkerque, which town was taken by Louis XIV., and given up to the English, according to an agreement with Cromwell. By the peace of the Bidasoa, 1659, Condé was reinstated in all his honours with a full amnesty. In 1668 he served under Louis XIV. in the conquest of Franche Comté. In 1672 Louis, having declared war against Holland, Condé commanded one of the corps d'armée which invaded that country; he took Wesel, and was wounded at the passage of the Rhine. In 1674 he gained the bloody battle of Senef, in Flanders, against the prince of Orange (William III. of England), and relieved Oudenaarde. In 1675, after Turenne was killed near Satzbach, Condé took the command of his army, and obliged Marshal Montecuccoli, who commanded the imperial troops, to retire. This was Condé's last campaign. Being tormented by the gout, he left the service and retired to his estate of Chantilly, where he spent his latter years in the society of men of letters. Racine, Boileau, Bossuet, and Bourdaloue were often his guests. He died at Fontainebleau in 1586. His personal character has been variously represented. Bossuet is too panegyrical. The memoirs of Count Jean de Coligny, who knew him intimately, and which were published in 1799, are too unfavourable, and probably exaggerated. (*Œuvres de Lemontey*, tome 5.) Like most of the men high in office at the court of Louis XIV., their master included, Condé seems to have had but imperfect notions of moral principle. Desormeaux has written the 'Life of Condé,' 4 vols. 12mo. The narrative of his campaigns is interesting in a military point of view.

The line of Condé became extinct in 1830 by the death of the duke of Bourbon, son of the last prince of Condé, who, in the wars of the revolution, commanded a corps of French emigrants on the Rhine. The duke of Bourbon never assumed the title of prince of Condé. His only son, the young duke d'Enguien, was put to death by Bonaparte in 1804. The Duke de Bourbon himself died at Chantilly soon after the revolution of July, 1830, in a mysterious manner, which was much commented upon in the newspapers of the time.

CONDENSATION. [EXPANSION.]

CONDILLAC (ETIENNE BONNOT DE), was born at Grenoble in the year 1715, and was distinguished at an early age for his taste for metaphysical inquiries. The works of Locke chiefly attracted his attention, and were the cause of his publishing, in the year 1746, his 'Essai sur l'origine des connoissances humaines,' a work intended to promulgate principles founded on those of the English philosopher. The tendency which Locke's works had naturally produced of tracing all knowledge back to sensations, induced him to publish, in 1749, his second work, the 'Traité des Systêmes,' which was designed to oppose the theories of Leibnitz, Spinosa, and others, as based upon abstract principles, rather than what he conceived the more solid foundation of experience. His third work, 'Traité des Sensations,' is his master-piece. The author supposes a statue, which he has the power of endowing with one sense at a time. He first gives it *smell* alone, and then traces what may be the pleasures, pains, abstract ideas, desires, &c. of a being so limited with regard to its faculties; the other senses are then added, and the statue gradually becomes a complete human being. His works seem to have made but little impression on the mass in his time, but he was much sought after by those of high attainments. Diderot, J. J. Rousseau, and Duclos were among the number of his most intimate friends, and his celebrity spread so far, that he was appointed preceptor to the Prince of Parma. In this capacity he published his 'Cours d'études,' divided into 'L'Art d'écrire, l'art de raisonner, l'art de penser, and Histoire générale des hommes et des empires,' a series of works calculated to promote his own philosophical views. Having completed the education of his pupil, he retired to philosophical meditations. In the year 1768 he was admitted a member of the academy in the room of Abbé l'Olivet, though, strange to relate, he never afterwards attended the meetings of this learned body. His labours only terminated with his life, as he published his 'Logique' but a few months previous to his death, which happened in the year 1780. His 'Langue des Calculs,' a posthumous work, did not appear till the year 1798.

As a philosopher, Condillac rather deserves the term *ingenious* than profound. He has the art of developing his own views in the most entertaining manner possible; and in working out his theories he almost becomes prolix. Not satisfied with giving his statue smell alone, examining its situation in that state, and then adding the other senses, he considers it endowed with each of the other senses alone, and thus extends his 'Traité des Sensations,' which is at best but a pleasing example, to a thick volume.

Professor Stewart has justly censured the French for taking for granted that Condillac was a correct interpreter of Locke, and at the same time is somewhat severe on their Locke mania. He observes that this nation rarely takes up a system till every other nation has done with it; that it began to take Descartes in the place of Aristotle, when Newton had overthrown Descartes everywhere else; and looked upon Locke (as interpreted to them) as infallible, when England had already modified his doctrines. It is clear enough that Condillac was not a faithful interpreter of Locke. He had, perhaps wilfully, overlooked a very short chapter in the 'Essay on the Human Understanding'—'Of simple Ideas of Reflection.' Locke traced all our knowledge to sensation *and reflection;* Condillac stopped at sensation alone, and thus produced a system which cannot be surpassed in sensualism. When his statue has smell alone, he tells us, that if a rose be presented to it, it is certainly, with respect to us, a statue smelling a rose; but is, with respect to itself, nothing but the smell of the flower; the very perceiving subject is to itself nothing but an odour. And this was supposed to be a faithful exposition of the doctrines of Locke—of Locke, who allows the mind ideas of reflection, 'when it turns its view inward upon itself, and observes its own actions about those ideas it has;' and therefore can never have conceived that a perceiving being cannot divide itself in thought from the thing perceived. Some have thought that Condillac imbibed this notion, of a sensation being to the mind only a modification of itself, from Berkeley: but though Berkeley denied an inanimate substratum to our sensations, he certainly never went so far as to make the mind take itself for a self-perceiving sensation.

Condillac's opinion of the importance of words is much more akin to Berkeley's views: without them he contends we should have had no abstract ideas (in the Locke language); that we can only think of a particular image, and our thinking of any general idea, as *man*, is an absurdity; that having observed something in common to several individuals, as *Peter*, *John*, &c., we agree to call them all by the term *man*, and that the general idea is nothing but an idea of such term, or an acknowledgment that the term may fit each of the individuals equally well. Something very like this may be found in Berkeley's Introduction to his 'Treatise concerning the principles of Human Knowledge.'

The knowledge of our own and of other bodies, according to Condillac, commences with the sensation of touch. He gives his statue that sensation, and making it strike itself with its hand, states that while this hand as it were, says, on the consciousness of a sensation, '*C'est moi*' (It is I), the part touched echoes the declaration: thus the statue concludes that both parts belong to its individual self, in other words, that it has a corporeal body. On the other hand, if the statute touch an extraneous body, though the hand says '*C'est moi*,' it perceives there is no echoing sensation, and therefore concludes there is another body besides its own.

Condillac is much lauded by M. La Harpe for his ingenious views of the progress of language. He begins with the language of action, and in the absence of abstract ideas among some American tribes, who have scarcely any language but that of cries and gestures, he finds a support for his hypothesis that these ideas depend on words. The language of action, he says, preceded that of words, and this latter language still preserved much of the character of its predecessor. Thus the elevation and depression of the voice succeeded the various movements of the body. Variation of accent was so much the more necessary as the rude people, who were beginning to lay aside their language of gesture, found it easier to express their meaning by changing emphasis than inventing words. This emphatic style of speaking is in itself a sort of prosody, which insensibly leads to music, and the accompanying of these sounds by gestures leads to dancing, all of which the Greeks called by the common name μουσική, music. He then proceeds to trace the drama, rhetoric, and even the peculiarity of the Greek language by regular steps, the language of action having formed the basis of all.

On the whole, the philosophy of Condillac is a system of ultra-sensualism; by omitting reflection (in Locke's sense of the term*), he makes the mind perceive nothing but sensations, itself being to itself nothing but a combination of sensations, and thus turn which way we will, there is no escape from the world of sense.

The fullest account of Condillac's philosophy for those who do not wish to peruse his voluminous works, will be found in La Harpe's 'Cours de la Littérature:' a short account of the influence of Locke on France through his medium is given in Professor Stewart's 'Philosophical Essays;' but those who wish to hear Condillac himself without much trouble, will find his system most fully and pleasantly developed in the 'Traité des Sensations.'

CONDIMENTS. [AROMATICS.]

CONDITION. Two possible events, A and B, may be so related, that (1) when A becomes event or effect, B also shall become event or effect: (2) or so that B being already event or effect, when A becomes event or effect, B may either cease to be event or effect, or may be diminished as to event or effect, or enlarged as to event or effect. This kind of relationship may be expressed by the term, condition, and the words by which this condition is made, may be any that are free from ambiguity. In case (1) where A must happen before B can, this may be called a condition precedent. In case (2) where B, already being event or effect, is extinguished or modified by the subsequent event A, this may be called a condition subsequent. The events may be more than two, and the condition which expresses their relation may be more or less complicated, but the general nature of the relation will still subsist. The application of this principle to legal questions is simply this:—Conditions precedent are conditions annexed to any gift of an estate or interest which at law must be strictly performed, before such estate or interest can vest in the person designated by the gift. Conditions subsequent are when the estate or interest is already vested, but its continuance in the person in whom it is vested, depends on the breach or performance of the conditions.

---

* We insert this parenthesis, because the word '*reflection*' may be found in the works of Condillac, but signifying nothing more than the looking back on past impressions.

Cases may arise, and in construction of agreements and particularly of wills often do arise, in which it is not easy to say whether the condition is precedent or subsequent; but in general, the difficulty arises rather from certain technical rules of law applicable to the construction of instruments, than from the bare terms in which conditions are expressed.

Littleton's description of an estate upon condition is this: (325) 'Estates which men have in lands or tenements upon condition, are of two sorts, viz., either they have estate upon condition in deed, or upon condition in law, &c. Upon condition in deed is, as if a man by deed indented, enfeoffes another in fee simple, reserving to him and his heires yearely a certaine rent payable at one feast, or divers feasts per annum, on condition that if the rent be behind, &c., that it shall be lawful for the feoffor and his heires into the same lands or tenements to enter, &c. And if it happen the rent to be behind by a week after any day of payment of it, or by a moneth after any day of payment of it, or by half a yeare, &c., that then it shall be lawful to the feoffor and his heires to enter, &c. In these cases, if the rent be not paid at such time, or before such time limited and specified within the condition comprised in the indenture, then may the feoffor and his heires enter into such lands and tenements, and them in his former estate to have and hold, and the feoffee quite to ouste thereof. And it is called an estate upon condition, because that the estate of the feoffee is defeasible if the condition be not performed,' &c.

An estate thus given is liable to be defeated, that is, the gift upon non-performance of the condition may be resumed by the giver, or his heirs: this is a condition subsequent, that is, subsequent to the vesting of the estate in the feoffee or grantee

The following example from Littleton will show the difficulty which has been introduced into the construction of conditions by the peculiar character of the laws of England (Litt. 350): 'If land be granted to a man for term of five yeares, upon condition, that if he pay to the grantor within the two first yeares, forty markes, that then he shall have fee, or otherwise but for term of the five yeares, and livery of seisin is made to him by force of the grant, now he hath a fee-simple conditionall, &c. And if in this case the grantee do not pay to the grantor the fortie markes within the first two yeares, then immediately after the first two yeares past, the fee and the freehold is and shall be adjudged in the grantor, because that the grantor cannot after the said two yeares presently enter upon the grauntee, for that the grauntee hath yet title by three yeares to have and occupie the land by force of the same grant. And so because that the condition of the part of the grantee is broken, and the grantor cannot enter, the law will put the fee and the freehold in the grantor.'

On this Coke remarks, that many are of a different opinion from Littleton, because the fee-simple is to commence upon a condition precedent (of which class the condition in the case put by Littleton clearly is), and yet 'here Littleton, of a condition precedent doth (before the performance thereof) make it subsequent.' And yet Littleton is right, for the legal effect of the livery of seisin is to pass a present estate of freehold.

It is a rule of law that none but the grantor and his heirs can have the benefit of a condition; and that any conditions are good which are not unlawful, impossible, immoral, or absolutely inconsistent with the nature of the estate given. An instance of the last kind of condition (Littleton, 360) would be a feoffment, or a devise in fee, upon condition that the feoffee or devisee should not alien the land to any person: such a condition, being inconsistent with the estate given, is void.

Before the Statute of Westminster 2, *De Donis Conditionalibus*, if lands were given to a man and the heirs of his body, as soon as he had issue of his body, this fee-simple conditional became for some purposes, and among them, for alienation, an absolute fee-simple. The effect of this statute was to convert conditional fee-simples into estates tail. [Tail, Estates.]

Conditions in English law were of feudal origin. The rents and services of the feudatory were considered as conditions essentially annexed to his fief, and were called conditions in law, or implied conditions. The neglect of these conditions was a forfeiture of the fief to the lord of whom he held his lands. Expressed conditions, or conditions in deed, were subsequently introduced, but as we have already shown, they savoured of their origin in this, that the donor's remedy for breach of conditions was limited to him and his heirs. But the doctrine of conditions has long ago been extended to all such cases as the complicated relations of a rich and populous country require, and, as in the Roman law, so now in the law of England, conditions may form a part of every written instrument by which men regulate their mutual dealings, or dispose of their property. These conditions and the construction of them, vary with the nature of the instrument of which they form a part; and the construction of such conditions is further subject to some variations, owing to the different aspect under which they are regarded by courts of law and equity.

Those conditions which are of most practical importance, are the conditions of Bonds, Leases, Mortgages, and Wills. The last head includes conditions annexed to portions and Legacies, which have given rise to a great number of disputes, and to numerous and not always consistent judicial decisions.

As to conditional limitations of real property, and the difference between them and remainders and conditions (this being a matter purely technical), the reader is referred to Fearne's *Essay on Contingent Remainders*; and Butler's note on Co. Litt., note 94.

CONDITION (Mathematics) is used in nearly the same sense as in common life. Thus the proposition, to describe an equilateral triangle upon a given straight line, is not to describe *any* triangle, but a triangle under the following *conditions*; that it must be equilateral, and that it must have a given line for its base.

An *equation of condition* means an equation which will not always be true, but requires certain conditions to be satisfied; and is distinguished from an *identical equation*, or one which is true independently of all conditions. Thus, $x + x = 2x$ and $(a + x)\ (a - x) = a^2 - x^2$ are identical equations: they are true for all values of x and a. But $x + 2 = 3$, and $4x - x^2 = 3$ are equations of condition: the first cannot be true unless $x = 1$, nor the second unless $x = 1$, or $x = 3$.

But the term *equation of condition* has a more technical meaning in the application of mathematics to the sciences of observation. Suppose, for example, that x, y, and z are certain quantities to be found, but which cannot be observed directly: they are however connected with each other by an equation, say $a x + b y + c z = h$, where, a, b, c, and h are different at different times, or for different circumstances of observation, but still are so connected that the preceding equation must be true; and where a, b, c, and h can either be observed, or computed from observations. Let a_1, b_1, c_1, and h_1 be the results of a first observation; a_2, b_2, &c., of a second; then for n different observations, we have the n following equations:—

$$a_1 x + b_1 y + c_1 z = h_1$$
$$a_2 x + b_2 y + c_2 z = h_2, \text{ \&c.}$$

If the observations be all correct, any three of these will give the same values of x, y, and z: but if, as must happen, there be errors in every observation, the results of each triad will differ slightly from those of the rest. For the method of solving the whole set, so as to produce the most probable result, see Probabilities, Theory of, and Least Squares, Method of. This is what is called the formation of *equations of condition*.

CONDOM, a town in the department of Gers in France, situated on the river Baise, a tributary of the Garonne, about 350 miles in a direct line south by west of Paris, in 43° 58′ N. lat., and 0° 22′ E. long.

Before the revolution, this town contained several religious houses, and a college directed by the Fathers of the Oratory. There are at present two hospitals for sick children and for soldiers. The population in 1832 amounted to 3578 for the town, or 7144 for the whole commune. The town is quite surrounded with vineyards, and considerable trade is carried on in the wine and brandy that these produce; but the chief trade is in wheat and flour. The river on which Condom stands gives motion to a great number of corn-mills. A considerable quantity of leather, esteemed the best in this part of the country, is made and sent to Bordeaux; some woollen-yarn is spun, and quills are prepared for writing: cork-cutting is also an important branch of the trade of the place, and paper, tiles, and pottery are made. Several roads meet at Condom; and it has been proposed to open a further line of communication by rendering the Baise navigable between this town and Nérac, where the navigation now commences. Condom was pillaged by the Huguenots in the religious wars of the sixteenth century.

Condom was formerly an episcopal town. The bishopric was established in 1317 by a division of that of Agen. The revenue of a Benedictine abbey formed the revenue of the see, the abbot became the first bishop, and the monks (who were afterwards secularized) formed the chapter. Bossuet filled for some time the see of Condom.

Condom is the chief town of an arrondissement containing, in 1832, 71,487 inhabitants. The district of Condomois, of which it was formerly the capital, was bounded on the north by the Agenois and Bazadois, on the east by La Lomagne (a part of Armagnac), on the south by Armagnac Proper, and on the west by the district of Marsan. [CHALOSSE.] Some of our authorities comprehend the district of Marsan in the Condomois. In it were the towns of Nérac (pop. 3566 for the town, 6327 for the whole commune) and Mezin (pop. 1962 for the town, 3146 for the whole commune).

CONDOR, or CUNTUR (Zoology), one of the largest of the known *Vulturidæ*, of whose size and strength such exaggerated accounts were formerly current, and whose true history and dimensions have been ascertained only within these few years. The bird was compared to the Roc of the Arabian romance writers; nay, by some, it was considered identical with that monstrous oriental conception. In the 'Musæum Tradescantianum,' under title 'Clawes,' we find 'the claw of the bird Rock, who, as authors report, is able to trusse an elephant.' This may have been the claw of a condor, exaggerated by some of the artists who wrought extraordinary zoological forms for the collectors of the day. Near the passage quoted there is a notice of a toucan's (Aracari's) bill, and other parts of birds from Brazil and 'the West Indias.' In the old French Encyclopédie, after noticing Condamine's statement, the writer adds that it is believed that these birds exist also in the region of Sophala, of the Caffres, and of Monomotapa, as far as the kingdom of Angola, and that it is supposed that they do not differ from those which the Arabians call *rouh*.

Ray, in his Synopsis, confesses that, such was the enormous and almost incredible magnitude attributed to it, that he at one time considered the Condor the mere offspring of fiction, that he dared not insert the bird in Willughby's Ornithology, and that it was to Sir Hans Sloane, who possessed a feather plucked from the wing of one shot on the coast of Chile, and presented to him by Captain Strong, who gave him at the same time the measurement of the bird, that he first owed his belief of its existence.

Joseph Acosta, Garcilasso de la Vega, and John de Laet, all speak of this vulture. Acosta says that the birds called condors are of great magnitude, and of such strength that they are not only able to eviscerate and devour a sheep, but even an entire calf. Garcilasso enumerates among the rapacious birds those called *Cuntur*, and corruptly by the Spaniards *Condor*, and states that some of those killed by the Spaniards measured fifteen or sixteen feet from tip to tip of the extended wings. He further observes that nature, in order to temper their ferocity and strength, has denied them the crooked talons which she has bestowed on the eagle, and given them claws more like those of the gallinaceous birds; but that she has, however, endowed them with a beak sufficiently strong to perforate and tear off a bull's hide, and to rip out its entrails. Two of them, he adds, will dare to attack a cow or a bull, and will devour it; 'neither do they abstain from the human race; but will set upon and slay, single-handed, boys of ten or twelve years, and it is by a providence of nature, for the protection of the flocks and the natives, that many are not hatched; for, if they were numerous, they would cause great slaughter among the herds, and the greatest damage to the inhabitants.' The account given by John de Laet, who speaks of the 'vasta moles' of the bird, is much the same with that of Garcilasso.

In relation to the condor's alleged attack upon children, Condamine notices a story of the Indians setting up a figure of a child made of very viscous clay; on this the condors were said to pounce, and so entangle their claws that they were held fast.

Feuillée and Molina speak more moderately of the condor; and the former gives the extent of the wings as eleven feet four inches only. The latter can hardly have seen the bird, though he was a native of Chile; for he lays down false characters for the distinction of the sexes, says nothing of the singular comb, and observes that the condor does not differ from the lämmergeyer (*Gypäetus barbatus*, *Vultur barbatus*).

Abbeville assures his readers that it is twice the size of the most colossal eagle. Desmarchais gives eighteen feet as the extent of the wings, which, he says, are so enormous that the bird can never enter the forest; and he adds that it will attack a man, and carry off a stag. Linnæus seems to have drawn up his account of the habits of the bird from the writers above noticed, some of which he quotes. 'It preys,' says Linnæus, 'on calves, sheep, nay, on boys of ten years; a pair will tear up and devour a cow;' and he adds that the rushing of its wings, as it nears the earth, renders men planet-struck, as it were, and almost deafens them—'in terram devolans, susurro attonitos et surdos fere reddit homines:' he makes the alar extent from thirteen to sixteen feet. These marvellous stories were left to work upon the minds of men always prone to receive the wild and the wonderful; for, till within the last twenty-five years, one or two specimens, and those not perfect, were the only evidences of the condor in the cabinets of Europe.

The *Great Vulture of the Andes* was a striking instance of the way in which things imperfectly known are exaggerated; it was with the Condor, observes Vieillot, as it was with the Patagonians,—both shrank before examination. To the scrutiny of the Baron Von Humboldt and of M. Bonpland we owe the reduction of the bird to its proper dimensions. Nestling in the most solitary places, often upon the ridges of rocks which border the lower limit of perpetual snow, and crowned with its extraordinary comb, the condor for a long time appeared to the eyes of Humboldt himself as a winged giant, and he avows that it was only the measurement of the dead bird that dissipated this optical illusion. The grand scenery amid which it is found had a precisely contrary effect on Lieutenant Maw*, who, in describing his descent into the deep and narrow valley of Magdalena, says, 'whilst descending, several condors hovered round us, and about the rocks on which they build their nests; but so vast was the scale of the rocks and mountains, that even these immense birds appeared quite insignificant, and I doubted for a time that they were condors.'

Under the name of *zopilote*, a word derived from the Mexican word *tzopilotl*, which is said to signify 'king of the vultures,' M. Vieillot places the condor in the same genus with the bird usually termed 'the king of the vultures' (*Vultur papa* of Linnæus and others), and the Californian vulture (*Vultur californianus*, Lath. and others). His Latin name for this genus is *gypagus*. Mr. Bennett adopts this arrangement, and, as his description of the bird is accurate, and evidently made from personal observation, we give it the preference. 'The condor,' writes Mr. Bennett, whose loss is deeply felt by zoologists in general, and by the Zoological Society in particular, 'forms the type of a genus, a second species of which is the *Vultur papa* of Linnæus, the king of the vultures of British writers. They are both peculiar to the New World, but approach in their most essential characters very closely to the vultures of the Old Continent, differing from the latter principally in the large, fleshy, or rather cartilaginous, caruncle which surmounts their beaks; in the large size of their oval and longitudinal nostrils, placed almost at the very extremity of the cere; and in the comparative length of their quill-feathers, the third being the longest of the series. The most important of these differences, the size and position of their nostrils, appears to be well calculated to add to the already highly powerful sense of smell possessed by the typical vultures, and for which these birds have been almost proverbially celebrated from the earliest ages. There is also a third species, the Californian vulture, two noble specimens of which, the only pair in Europe, are preserved in the Society's museum, rivalling the condor in bulk, and agreeing in every respect with the generic characters of the group, except in the existence of the caruncle, of which they are entirely destitute.

---

* 'Journal of a Passage from the Pacific to the Atlantic,' &c.; by Henry Lister Maw, Lieut., R.N.

'In size, the condor is little, if at all, superior to the bearded griffin, the lämmergeyer of the Alps, with which Buffon was disposed conjecturally to confound it, but to which it bears at most but a distant relation. The greatest authentic measurement scarcely carries the extent of its wings beyond fourteen feet; and it appears rarely to attain so gigantic a size. M. Humboldt met with none that exceeded nine feet, and was assured by many credible inhabitants of the province of Quito that they had never shot any that measured more than eleven. The length of a male specimen somewhat less than nine feet in expanse was three feet three inches from the tip of the beak to the extremity of the tail; and its height, when perching, with the neck partly withdrawn, two feet eight inches. Its beak was two inches and three-quarters in length, and an inch and a quarter in depth when closed.

'The beak of the condor is straight at the base, but the upper mandible becomes arched towards the point, and terminates in a strong and well-curved hook. The basal half is of an ash brown, and the remaining portion, towards the point, is nearly white. The head and neck are bare of feathers, and covered with a hard, wrinkled, dusky reddish skin, on which are scattered some short brown or blackish hairs. On the top of the head, which is much flattened above, and extending some distance along the beak, is attached an oblong firm caruncle or comb, covered by a continuation of the skin which invests the head. This organ is peculiar to the male. It is connected to the beak only in its anterior part, and is separated from it at the base in such a manner as to allow of a free passage of the air to the large oval nostrils, which are situated beneath it at that part. Behind the eyes, which are somewhat elongated, and not sunk beneath the general surface of the head, the skin of the neck is, as it were, gathered into a series of descending folds, extending obliquely from the back of the head over the temples, to the under side of the neck, and there connected anteriorly with a lax membrane or wattle, capable of being dilated at pleasure, like that of the common turkey. The neck is marked by numerous deep parallel folds, produced by the habit of retracting the head, in which the bird indulges when at rest. In this position scarcely any part of the neck is visible.

'Round the lower part of the neck, both sexes, the female as well as the male, are furnished with a broad white ruff of downy feathers, which forms the line of separation between the naked skin above and the true feathers covering the body below it. All the other feathers, with the exception of the wing-coverts and the secondary quill feathers, are of a bright black, generally mingled with a greyish tinge of greater or less intensity. In the female, the wing-coverts are blackish grey; but the males have their points, and frequently as much as half their length, white. The wings of the latter are consequently distinguished from those of the female by their large white patches. The secondary quill feathers of both sexes are white on the outer side. The tail is short and wedge-shaped. The legs are excessively thick and powerful, and are coloured of a bluish grey, intermingled with whitish streaks. Their elongated toes are united at the base by a loose but very apparent membrane, and are terminated by long black talons of considerable thickness, but very little curved. The hinder toe is much shorter than the rest, and its talon, although more distinctly curved, is equally wanting in strength; a deficiency which renders the foot much less powerful as an organ of prehension than that of any other of the large birds of the raptorial order.'

Geographical Distribution.—The Andes, and the greater part of the vast mountain-chain which runs up South America, to lat. 7° N., but most common in Peru and Chile.

Habits, Nest, &c.—The condor is found most frequently at an elevation of from 10,000 to 15,000 feet above the level of the sea, and there they are to be seen in groups of three or four, but never in large companies, like the true vultures. Many of the clusters of rocks and of the elevated plateaux are named after them: *Cuntur Kahua*, *Cuntur Palti*, and *Cuntur Huacana*, for example—names which, in the language of the Incas, are said to signify, the Condor's Look-out, the Condor's Roost, and the Condor's Nest. In this rarefied atmosphere the bird breathes freely, and resorts to the plains only when impelled by hunger. Then two of them will attack the vicuna, the guanaco, the heifer, and even the puma, the lion of South America, persecuting the tormented quadruped till, overpowered, it falls beneath the wounds inflicted by their claws and beaks, groaning, and protruding its tongue. Upon this and the eyes, their favourite morsels, the condors instantly seize, and the bloody banquet is continued till they are quite gorged. Humboldt saw them after such repasts sitting sullen and sombre on the rocks; and when thus overloaded, they will suffer themselves to be driven before the hunter rather than take wing. But he has also seen them, when on the look-out for prey, and especially on serene days, soaring at a prodigious height, as if for the purpose of commanding the most extensive view. 'C'est l'oiseau,' says Cuvier, speaking of the condor, 'qui s'élève le plus haut.' With regard to the stories of their carrying off children, Humboldt never heard of an instance, although the infants of the Indians who gather snow for sale are frequently left sleeping in the open air in the midst of the haunts of these birds. He often approached within a few feet of three or four of them as they sat on the rocks, but they never manifested any disposition to attack him; and the Indians of Quito assured him that men have nothing to fear from condors: he admits indeed that two of these vultures would be dangerous antagonists for a single man to cope with; and Sir Francis Head describes a severe struggle between one of them and a Cornish miner with his usual graphic power. When the bird descends into the plains, it rarely perches on trees, preferring the ground, for standing and walking on which its toes and straight claws are better adapted.

Humboldt was assured that the eggs, which are white, and three or four inches in length, are deposited on the bare rock without any border of straw or other defence. The young ones are said to remain with the female during one year. The nestlings have no feathers; their bodies for some months are covered with a very fine curling whitish down or hair, something like that of young owls; and they are so puffed out by this envelope, that they look almost larger than adults. At the age of two years, the condor is not yet black, but of a yellowish brown; up to this time, the female has no appearance of the white ruff (*gollila* of the Spaniards), and it is owing to want of observation on this change of plumage that many naturalists and travellers, nay, the inhabitants of Peru themselves, talk of two species of condor, the black and the brown (*Condor negro y Condor pardo*). Thus Lieutenant Maw, in the sequel to the passage above quoted, says, 'There were two kinds of condors; one dark brown, the other white on the back, with half the upper side of the wings next the back, and a white ring round the neck.'

Chace.—At Peru, Quito, and in the province of Popayne, condors are taken alive with the lasso. To this end a cow or a horse is killed. Down come the condors, and are permitted to gorge themselves. Then the Indians, with their lassos, appear on the scene, and soon capture them. When one of the birds finds itself hampered, it makes incredible efforts to raise itself in the air, and succeeds, after vomiting freely. The Spaniards call this sport *correr buitres*, and it is, next to the bull-feasts, the great amusement of the country people. In other countries it is said that poisonous herbs are placed in the belly of the quadruped that serves as a bait, and then the condors appear as if intoxicated after their meal.

The tenacity of life exhibited by the condor almost rivals the account which we have given of the endurance of the grisly bear. (Bear, vol. iv. p. 88.) Humboldt relates that at Riobamba he saw some Indians first strangle one with a lasso and hang it on a tree, pulling it forcibly by the feet for some minutes. The lasso was hardly removed when the condor arose, and walked about as if nothing extraordinary had happened. At less than four paces, three balls were then discharged from a pistol at it, all of which entered its body, wounding it in the neck, chest, and abdomen: the bird still kept its legs. Another ball broke its thigh, and brought it to the ground; but the wretched creature did not die till after an interval of half an hour. Ulloa asserts that in the colder parts of Peru the skin of the condor is so closely covered with feathers, that eight or ten balls may be heard to strike it without penetrating its body.

This celebrated vulture, *Vultur Gryphus* of Linnæus, *Gypagus Gryffus* of Vieillot, *Sarcoramphus Gryphus* of Duméril, is said to possess a most exquisite sense of smelling. It may be doubted, however, whether, as in other vultures, the eye is not at least as great an assistant to the bird in discovering its prey as the nostrils are. (BIRDS, vol. iv. p. 429). Lieutenant Maw saw the condor's quill used as a pen in the Cordillera (Toulca).

The Zoological Society of London have now made this form, of which such romantic tales were told and credited, familiar to the whole population of the metropolis. It is a striking contrast, to rise from the perusal of one of these marvellous stories, and look at the living bird in the Regent's Park

[Sarcoramphus Gryphus, male.]

CONDORCET, MARIE-JEAN-ANTOINE-NICOLAS CARITAT, MARQUIS DE, was born in Picardy in 1743. His family owed their name and title to the castle of Condorcet, near Nion, in Dauphiny. His uncle, the bishop of Lisieux, who died in 1783, superintended his education, and was the means of procuring for him the most powerful patronage as soon as he was old enough to be introduced into public life. He first distinguished himself as a mathematician, and his success in this department soon opened to him the door of the Academy of Sciences.

It is on his application of philosophy to subjects connected with the happiness of mankind and the amelioration of social institutions that his fame chiefly rests. The friend of D'Alembert and of his illustrious contemporaries, Condorcet was one of the warmest and most distinguished of Voltaire's disciples. He cannot, it is true, be placed in the first rank, either as a deep thinker or original writer; nevertheless his meditative and lofty mind, his unabated zeal in the pursuit of truth, his generous ardour, which never cooled or shrunk from the difficulties which it had to encounter, his perseverance in applying himself to all sorts of useful pursuits, and the multiplicity of his labours, have all contributed to assign him a conspicuous place among those who have exercised an influence over the destinies of his country.

His philosophical views have been widely circulated, and the practical effect of them is still visible in our days. The main doctrine which he sought to inculcate, and which is contained in his 'Esquisse des Progrès de l'Esprit humain,' was the perfectibility of man, considered both in his individual and social capacity. According to him, the human frame and intellect, by the aid of time and education, would infallibly attain to perfection. This was the creed which he proposed to substitute in the place of the sanctions of morality and religion. This singular notion, with which he was so deeply imbued, has given to his philosophy a peculiar and special character, which distinguish it alike from the sceptical fatalism of Voltaire and the gloomy dogmatism of Diderot. In the philanthropic mind of Condorcet philosophical speculations were blended with the deepest sympathy for his fellow men, and the most unwearied activity in promoting all such reforms as he thought useful. Of his magnanimity and elevation of soul he gave ample proof in the heroic conduct which he pursued in the hour of difficulty and danger. Proscribed by the Convention as a *Girondin*, he voluntarily quitted the house of his friend Madame Verney, which had afforded him an asylum during eight months of the first revolution, rather than expose her to the consequences of a decree which might have made it a capital crime to harbour or conceal an outlawed deputy.

Houseless, and wandering about the country round Paris, he endeavoured to conceal himself in the numerous quarries with which its neighbourhood abounds. At last the pressure of hunger drove him into a small inn in the village of Clumart, where he incautiously betrayed himself by exhibiting a pocket-book obviously too elegant for one in so destitute a condition. He was arrested, and though exhausted by want and fatigue, and with a sore foot occasioned by excessive walking, he was conveyed to Bourg-la-Reine, and thrown into a dungeon. On the morrow (28th March, 1794), he was found dead in his cell, having put a period to his existence by swallowing poison, which he always carried about him in order to avoid the ignominy of the scaffold. His mathematical works are numerous, consisting in great part of memoirs in the Transactions of the academy. In pure mathematics he devoted himself mostly to the development of the differential and integral calculus: he lived during the time when the higher parts of that science began to assume their present powerful form; and his labours on the subject of differential equations must preserve his name in connection with their history. His applications of mathematics are,—1, the problem of three bodies, in which he had no particular success; 2, the application of the mathematical theory of probabilities to judicial decisions, at that time a new and ingenious speculation, the grounds of which are generally misunderstood, but which was treated by Condorcet with a degree of power which entitles his work to no mean rank among those which have led the way to a perception of the extensive bearings of the integral calculus. Condorcet is not in the very first rank of mathematicians, but very high in the second. As a literary author, his 'Eloges des Académiciens morts depuis 1699,' procured for him the perpetual secretaryship of the Academy of Sciences, and furthered his election to the French Academy. Though decidedly inferior to Fontenelle's 'Eloges Académiques,' both in point and simplicity, they nevertheless show Condorcet to be a pure and elegant writer, as well as a good judge of the merit of others. His Lives of Voltaire and Turgot, in which these qualities are most apparent, are moreover distinguished by the enlightened philanthropy, the philosophical zeal, and that desire for improvement, which was always the strongest feeling in the author's heart. The style in which they are written is clear, and if somewhat monotonous, is not altogether devoid of force and spirit. Besides his numerous works (of which he had not time to undertake a regular and careful revision), he contributed several articles to the papers entitled the 'Feuille Villageoise,' and the 'Chronique de Paris.' But the grand work of Condorcet was his Esquisse du Progrès de l'Esprit humain, which he wrote while he was seeking refuge from proscription, and for which he had no other materials except such as he had treasured up in his own vast and capacious memory: it is a work more remarkable for depth of thought than brilliancy of style.

Another of his most remarkable productions was his 'Plan for a Constitution,' which he presented to the Convention, at whose request he had undertaken to draw up a report on public instruction. His treatise on this subject abounds in enlarged and lofty views, and contains the justest notions on the art of expanding the faculties and forming the character.

Good-nature and kindness were the foundation of his dispositions. If he was deficient in any thing, it was in imagination. His outward deportment was cold and reserved, and characterized by a certain degree of awkwardness and timidity. Nevertheless he possessed more real warmth of feeling and greatness of soul than those unacquainted with him would have suspected. D'Alembert used to characterize him as a volcano covered with snow. His private as well as public conduct was firm, disinterested, and straightforward; and being fully satisfied that a system of equality was the only one compatible with the happiness and real interests of mankind, he made no account of his own rank, title, or fortune, but was willing to sacrifice them all to promote the darling object of his hopes and wishes.

Under the old régime, he refused the request of the Academy in 1777 to pronounce an éloge on the Duc de la Vrillière, minister of Louis XV. He subsequently resigned the place which he held under the administration, that he might avoid being brought into contact with M. Necker, whom he suspected of having intrigued against his friend Turgot. In the earlier period of the Revolution, Condorcet used every effort to bring about those changes which he had so often desired to see accomplished for the good of his country, and became an active member of the Comité des Subsistances.

It was on the occasion of being summoned, in 1789, by Louis XVI., to deliberate upon the best mode of providing for the wants of Paris, that he was forcibly struck with the intelligence displayed by the king in the discussion of this difficult and important question. 'After listening to him,' says Condorcet, 'we all looked at each other with astonishment, and felt at once that the course which he advised was in fact the only real one.'

Being called to the Convention, after the fall of the monarchy, he rallied round the Girondins in order to oppose that portion of the Assembly known by the name of Montagnards from their occupying the highest seats in the Convention.

In his efforts to found a republic in France upon a philosophical basis, Condorcet sacrificed his life to his opinions. The purity and benevolence of his intentions, and his magnanimous devotion of himself to the cause in which he had embarked, are the imperishable records of his fame. His wife, who was of the family of Grouchy, and one of the most beautiful women of her day, distinguished herself by a correct and elegant translation of Adam Smith's 'Theory of Moral Sentiments.'

Condorcet's works have been collected and published in 21 volumes 8vo.

CONDOTTIE'RI, a word in the Italian language signifying captains, chiefs, or leaders, but most usually employed to designate soldiers of fortune, who raised corps of cavalry and infantry at their own expense, and engaged with princes and governments for their services as mercenaries. The practice of employing these mercenaries, which commenced in the early part of the fourteenth century, originated in the Italian princes and republics commuting the personal services of their subjects in war for pecuniary payments, with which they were enabled to hire mercenaries. As early as 1225, Genoa took the Count of Savoy into pay with 200 horse. Florence retained 500 French lancers in 1282. After the expedition of the Emperor Henry VII. in 1310, many soldiers of fortune remained in the service of Milan, Florence, and other states. Pisa appears, in 1343, to have disbanded a corps of German mercenaries, whose leader, Guarnieri, refusing to lay down his arms, levied contributions throughout the Italian states. In 1353, a band under the command of Fra Moriale, afterwards of Conrad Lando, called the Great Company, appeared in Italy, and extorted money from many of the Italian states. During the long and bloody wars between our Edward III. and France, foreigners from different parts of Europe, attracted by his fame and liberality, and allured by the hope of plunder, flocked to his standard. They were for the most part men of desperate fortunes, or unable to live at home according to their wishes. At the conclusion of the treaty of Bretigni in 1364, which restored peace to England and France, these soldiers, unable to relinquish a course of life to which they were accustomed, and being without other means of subsistence, were dispersed into the several provinces of France, where they possessed themselves of castles and fortresses, and associating themselves with the banditti of their vicinities, levied contributions on all within their power, and under the names of *companies* or *companions**, they became the terror of the peaceable inhabitants of the country. These ruffians formed altogether a body of 40,000 men, and were headed in many instances by some of the most experienced leaders of the time. They fought pitched battles with the troops of France, in which they gained victories. The misery which they occasioned only served to increase their numbers; for poverty and despair drove their victims to their standard. Even their excommunication by the Pope produced no abatement in their ferocity and rapine. At length, the war between Henry de Transtamare and Peter the Cruel for the succession to the crown of Castile furnished an opportunity to rid France of this scourge. Du Guesclin proposed to Charles V., King of France, to enlist these companies into his service and lead them into Castile. They accordingly engaged in this expedition, and in their way forced the Pope, then residing at Avignon, to give them a sum of money. From this time war became a trade in many parts of Europe, particularly in the Italian states, in which needy and desperate adventurers raised forces either by their pecuniary means or by their personal influence and reputation for conduct and courage, and engaged them for hire without the least consideration for the real or supposed justice of the cause in which they embarked. These forces were recruited from the refuse or the vagabonds of every state in Europe. The idle and profligate found in joining their bands a way of life which flattered their indolence and gratified their rapacity. The mode adopted for assembling them was by contracts with nobles who had authority over the loose and disorderly inhabitants of their estates, with captains whose address or bravery could allure adventurers to their banners, or with individuals whose poverty or choice made them offer themselves to princes or governments. In their discipline, though it was far from exact, and in courage and conduct in war, they were superior to the troops which could be then raised under the powers of the feudal system. Besides the profit which they gained on the ransom of their prisoners, their pay, according to the then value of money, appears to have been high (assuming them to have been as well paid as the other troops), and that of the private soldiers to have been at a much higher rate in proportion to the commanders and officers than in modern times. At the siege of Calais, in 1346, Edward Prince of Wales, for himself and retinue, for his wages of war, had 20*s.* a day. The pay of Henry Earl of Lancaster, for his 'wages of war,' was 6*s.* 8*d.* a day; 11 bannerets, 4*s.* a day; 193 knights, 2*s.*; 512 esquires, 1*s.*; 46 men-at-arms and 612 archers on horseback each 6*d.* a day. From the known rapacity of these mercenaries, it is not likely that they would have accepted lower terms than the other troops engaged in the same enterprize. According to Villani, they frequently demanded and received double pay with a premium or bounty-money of a month's pay on their engagements. It is difficult to state what was the exact amount, but it is conjectured that the pay of a private cuirassier was more than that of a subaltern officer of the present day. But their chief inducement to serve was the plunder of the towns or castles which they took, the contributions they levied, and the ransom of the prisoners. From this motive they were induced not only to spare their own men as much as possible, but to give quarter to their enemies. This rendered some of their battles nearly bloodless, a ludicrous instance of which occurred in one of the Italian wars. Piccinino advanced to attack Florence with an army of several thousand men. The place was defended by Capponi with another body, principally composed of mercenaries. The two armies engaged at Anghiari, a short distance from Florence. The battle lasted four hours. Piccinino was totally defeated, and fled to Borgo San Sepolcro with about a thousand men. The rest were made prisoners; only one man was killed, and this owing to the accident of his falling from his horse and being trodden under foot. Capponi, however, was unable to follow up his success, and his troops refused to advance till they had secured their plunder. Several other battles, equally bloodless, were fought in the wars of this period.

The Condottieri were notorious for bad faith in their engagements with the states they served. Their rapacity was equal to their bad faith; besides their pay, they exacted gratifications for every success. Such was the terror they inspired, that some of the Italian states paid them large sums not to pass through their territories. With the improvement of artillery and the introduction of musquetry the condottieri declined; but it is difficult to state the period of their extinction. Our countryman, Sir John Hawkwood, is said to have been the last, as he was beyond comparison the most eminent for his skill in military affairs. Sir John died at Florence in 1393 at an advanced age, and was buried with great pomp by the Florentines. There is a cenotaph to his memory in the church of Sible Hedingham, Essex, where he was born. (Froissart, Villani, Machiavelli, Aretin).

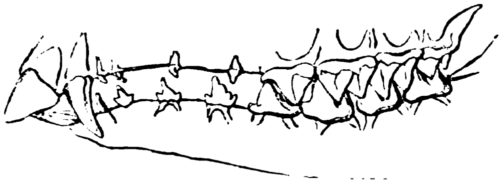
---

* They were sometimes called cotelli, probably a corruption of coltelli, from their bearing knives, or large daggers.

CONDYLURA (Zoology), Illiger's name for a genus of insectivorous mammifers, founded on the *sorex cristatus* of Linnæus. Cuvier observes that Desmarest was the first who made the dentition of the genus known.

Generic character.—*Body* thick, furry; *muzzle* much elongated, bordered with membranous crests, disposed star-like round the opening of the nostrils; no external *auricles; eyes* extremely small; *anterior feet* short, large, with five toes, furnished with robust claws proper for digging; *posterior feet* slender, with five toes; length of tail moderate.

Dental formula: incisors $\frac{2}{4}$, canines $\frac{1-1}{1-1}$, molars $\frac{8-8}{7-7}=40$.



[Teeth of Condylura cristata. F. Cuv.]

Lesson observes that the generic name rests on an error made by La Faille, who had represented the radiated mole with knotty swellings on the tail; but it is generally received by zoologists, and will be retained. The genus is analogous to the Moles and to *Scalops*.

Geographical distribution.—Entirely confined to North America, as far as is known at present. Speaking of some specimens of *Condylura longicaudata* in the Museum of the Zoological Society, obtained from Moose Factory, Hudson's Bay, Dr. Richardson says, 'They were not accompanied by any account of their habits, or notice of the exact locality where they were killed; but, as the most southern fur posts depending upon Moose Factory are situated upon the borders of Lake Superior, it is probable that they came from that quarter. Pennant's specimen was received from New York.'

The known species are not numerous. Example:—*Condylura macroura* (Harlan). *Thick-tailed, star-nose.* The following is Dr. Richardson's description of a specimen presented to him by the unfortunate Mr. David Douglas, and which the latter had procured on the banks of the Columbia River.

'The *head* is remarkably large; the body is thick and short, and becomes narrower towards the tail, and the hind legs are consequently nearer to each other than the fore-ones. The nose is rather thick, and projects beyond the mouth; it is naked towards its end, is marked with a furrow above, and terminates in a flat surface, which is surrounded by 17 cartilaginous processes, with two more anterior ones situated above the nostrils, and a pair of forked ones immediately below the nostrils. The surfaces of these processes are minutely granulated. Some white whiskers spring from the side of the nose, and reach about half the length of the head. There are others not so long on the upper and under lips. The *fur* on the body is very soft and fine, and has considerable lustre. It is longer than the fur of the other two known species. Its colour on the dorsal aspect is dark umber brown, approaching to blackish-brown. On the belly it is pale liver-brown. When the fur is blown aside, it exhibits a shining blackish-grey colour towards its roots. It is longer on the hind-head and neck than on the belly. The *tail* is narrow at its origin, but it suddenly swells to an inch and a half in circumference; it then tapers gradually until it ends in a fine point, formed by a pencil of hairs, about half an inch long. It is round, or very slightly compressed, and is covered with scales about as large as those on the feet, and with short, tapering, acute hairs, which do not conceal the scales. The hairs covering the upper surface of the tail are nearly black; those beneath are of a browner hue. The *extremities* are shaped almost precisely like those of the *Condylura longicaudata*. Only the palms and toes of the *fore-feet* project beyond the body. The palms are nearly circular, and are protected by a granulated skin, like shagreen. The sides of the feet are furnished with long, white hairs, which curve in over the palms. The five toes are very short, equal to each other in length, and, together with the back of the hands, are covered with hexagonal scales. The *fore-claws* are white, nearly straight, broadly linear, and acute, convex above and flat beneath. The palms turn obliquely outwards, which causes the fourth claw to project rather furthest; but the third one measures as much, the second is shorter, and the first and fifth are equal to each other, and a little shorter than the rest. The *hind-feet* are also turned obliquely outwards, and are scaly, with a few interspersed hairs above, and granulated underneath. The sides are narrow, and present a conspicuous callous tubercle, posterior to the origin of the inner toe. The hind legs are very short, and are clothed with soft brown hair, a tuft of which curves over the heel. There are no hairs on the sides of the hind-feet, like those which form a margin to the fore ones. The hind toes are longer than the fore ones, and are armed with more slender claws, which are white, awl-shaped, curved, and acute. They have a narrow groove towards their points underneath. Length of the head and body, 4 inches 3 lines; of the head, 1 inch 6 lines; of the tail, 2 inches 6 lines, including the pencil of hairs at its extremity, 3 inches 3 lines; naked part of the nose, exclusive of the awl-shaped processes, 2½ lines,' &c. (*Fauna Boreali-Americana*, vol. i., p. 284.)

Dr. Godman observes, that though the external ear in *Condylura cristata* is destitute of auricle, it is very extensive, and is situated at a short distance from the shoulder, in the broad triangular fold of integument connecting the fore-arm and head.

[Condylura Macroura.]

N.B.—M. Latreille has employed the term *Condylura* to designate a genus of *Branchiopoda*. [BRANCHIOPODA, vol. v. p. 340.]

CONE (Mathematics). In the most general sense, a cone is a surface formed by the motion of a straight line indefinitely extended in both directions, and which always passes through one given point (called the vertex). Any curve in space may be a guiding line (or directrix) through which the moving straight line may be made to pass.

But in common language the term cone is only applied to those general cones in which the directrix is a circle. Of these there are two kinds: the *oblique* cone, when the vertex is not in the axis of the directing circle (the axis being the perpendicular drawn to the plane of the circle through its centre); the *right* cone, in which the vertex is in the axis. The most prominent distinction between these two kinds of cones is this: that the oblique cone has two distinct sets of circular sections, whose planes are not parallel to each other [SUBCONTRARY], while the right cone has only one set of circular sections, all parallel to the directing circle.

The right cone is an infinitely extended surface, or consists of two cones (according to the most common notion) joined together by the vertex: but out of mathematics a portion of such cone is called a cone contained between the vertex and the directing circle, then called the *base*. In the rest of this article we shall use this meaning of the word.

The surface of a cone is one half the circumference of its base multiplied by the distance from the vertex to the circumference of the base (called the *slant side*). Thus the diameter of the base being 10 inches, or the circumference 31·416 inches, and the slant side being 20 inches, the surface of the cone is $\frac{1}{2} \times 20 \times 31\cdot416$, or 314·16 square inches. The cone unrolled gives a sector of a circle, the angle of which, in theoretical units (see ANGLE), is the circumference of the base divided by the slant side. Thus in the preceding instance 31·416 ÷ 20 or 1·5708 is the angle of the unrolled cone, which is a right angle.

The solidity of a cone is one third of the product of the area of the base and the perpendicular distance of the vertex from the axis. In the preceding instance the perpendicular aforesaid is

$$\sqrt{(\text{slant side})^2 - (\text{rad. of base})^2}, \quad \text{or } \sqrt{400 - 25}.$$

or $\sqrt{375}$, or 19·3649 inches. The area of the base is 3·1416 × 25, or 78·54 square inches: and this multiplied by one third of 19·3649, or 6·455, is 506·976, the number of cubic inches in the cone. The centre of gravity of a cone is in the axis, at a distance from the centre of the base equal to one fourth the distance of the vertex.

CONESSI BARK, the produce of Wright's anti-dysenterica, an apocynaceous plant, native of the coasts of the peninsula of India, especially in Malabar.

CONFARREATION. [MARRIAGE.]

CONFEDERATION OF THE RHINE. [BONAPARTE, p. 134.]

CONFERENCE at Hampton Court, was held on the 14th, 16th, and 18th January, 1604, in the presence of King James I., who took a leading part in the discussion, between nineteen bishops and inferior clergymen of the Church of England, and four Presbyterian or Puritan divines, to argue certain objections to the doctrine and discipline of the Church, respecting which the Puritans had petitioned his Majesty. It was followed by no result.

CONFERVÆ, a name sometimes considered synonymous with Algæ. [ALGÆ.] It is limited in systematic botany to a section of Algæ, consisting of simple tubular jointed species inhabiting fresh water.

CONFESSION means a solemn acknowledgement of some principle or fact. Hence the early Christians, who suffered imprisonment and other penalties from the Roman magistrates for having publicly declared their belief in the gospel, were called confessors. Others, in later times, acquired the same title from having embraced a life of austerity, or retired to some solitude or convent to do penance for their sins. Confession thus became synonymous with penitence, in which sense both words are understood by the Roman Catholics. The practice of confessing one's sins either in public before the congregation of the faithful, or privately to a priest, dates undoubtedly from the earliest ages of the church. In those times the Christians, scattered about the Roman world, and exposed to persecution, formed many small communities, living under the discipline of their presbyters, who knew every individual of their respective flocks, the members of which watched carefully over each other's conduct. Any gross irregularity or any compliance with heathen rites by one of the flock was sure to be known to the rest, and the offender was thereby subject to interdiction from Christian worship and communion. If he wished to be re-admitted to the communion of the church, he must publicly acknowledge and repent of his guilt, and submit to the penance imposed by the presbyter. This appears to have been the original mode of confession. It does not seem to be clearly determined when the practice of private, or 'auricular,' was substituted for public, confession. Cyprian, who lived towards the middle of the third century (*Epist.* Rom. 12), defines several kinds of sins for which penance ought to be done before the transgressor could be admitted to the communion; and in his treatise *De Lapsis in Persecutionibus*, he exhorts those who have fallen into heathen practices to confess their sins to the ministers of God, and thus unburthen their souls of their weight, 'because this satisfaction and the remission by the priest are acceptable to God.' Tertullian, who lived at the beginning of the same century, says (*De Pœnitentiâ*, ch. ix.) that penitence consists of three parts, confession, contrition, and satisfaction. In the eastern churches the custom of confessing sins before the assembled congregation was prevalent down to the fourth century, but the practice having led to scandal, especially on the occasion of a lady revealing that she had been seduced by a deacon, Nacterius, patriarch of Constantinople, abolished the custom, and removed the pœnitentiarius or priest ('qui præpositus erat pœnitentiæ') by whose advice the revelation had taken place. (Sozomen, *Histor.*, lib. vii.) Some passages of Chrysostom have been urged against the obligatory practice of confession. In Homily 11, he says, 'God commands that to him alone we should give account of our conduct, and to him we should confess;' which agrees with the principle and practice of the Protestant and reformed churches. Yet in his Homily of the Samaritan woman, he says, 'He who blushes now to reveal his sins to a man, and will not confess, at the last day will be arraigned not before one or two persons, but before the whole world.' In the fifth century, Pope St. Leo I., called the Great (*Epist.* Rom. lxxx. ch. 5), says that the priests ought not to enforce 'public confession of secret sins,' but that it is enough if the penitent confess them privately to a priest. This passage seems to throw some light on the transition from public to private confession. When and under what circumstances, confession, either public or private, was deemed absolutely necessary for the remission of sins, is another subject of controversy. Innocent III., in the fourth Lateran council, A.D. 1215 (Canon 21), made confession (meaning auricular or private) obligatory upon every adult person once a year, and that continues to be one of the rules of the Roman Catholic church to the present day, which numbers penitence among the sacraments. The Council of Trent, in its Catechism, defines it to be 'a declaration by the penitent of his sins, made to a priest in order to receive the penance and absolution.' Penitence therefore consists of four parts, confession, contrition, absolution, and penance; and it is a positive doctrine of the same church, that without the concurrence of all these parts or conditions, the sacrament is null and void. The penitent is also obliged to confess all the sins that he can recollect having committed and not confessed before, at least all the mortal sins, for Roman Catholic dogmatists draw a distinction between mortal and venial sins. By contrition it is meant that the penitent should fully repent of his guilt, and form at the same time a firm resolution not to sin again, without which repentance and resolution the absolution of the priest is of no avail, being always conditional upon a corresponding disposition on the part of the penitent. It is not therefore true, as it is often erroneously stated, that the priest can absolve from any sins by merely pronouncing the words, 'Ego te absolvo,' &c.; it is the penitent who, by his contrition and trust in the merits of the Saviour only, can give effect to the words of the priest, and in this respect the principle is common to all the Christian churches, except the formula of the absolution, which differs in some, while others omit it altogether. [ABSOLUTION.] The indispensable condition for obtaining absolution is often explained and inculcated from the pulpits and chairs of theology in Catholic countries, though it happens of course that ignorant or weak people overlook or misconceive the absolute necessity of inward contrition, and think that by merely confessing their sins and reciting the formula of repentance with their lips, they have acquitted themselves of their part, and that the priest can do the rest. Again, the priest absolves 'à culpâ, sed non à pœnâ;' he removes the guilt, but not the punishment, here or hereafter; and accordingly Roman Catholics admit a purgatory. The penance which the priest imposes consists generally of satisfaction to be given if the penitent has injured any one in his property, honour, &c., in a manner that can admit of reparation, and also of prayers, abstinence, or other religious practices to be performed. A really virtuous and enlightened confessor can often effect much good in this manner, and restore peace and happiness to families. The secrecy imposed on confessors is strict and unconditional; whatever be the crime of which a penitent may accuse himself, they are solemnly bound to keep it secret, under the most severe denunciations and penalties, both here and hereafter, that of excommunication ipso facto included. Notwithstanding the number of individuals who have exercised the office of confessors all over the Catholic world, and the manifold temptations to which they are exposed, there are few authenticated instances of their having betrayed their trust. That there may be other inconveniences likely to result from private confession, is another question, which it is not our business to discuss. Every priest is not a confessor, although every incumbent of a parish is. The qualifications of age, studies, character, &c. required in a candidate for the office of confessor, the solemn engagements he enters into, and the formalities with which he is consecrated by the bishop, may be seen in the professional works of discipline of the church of Rome, and, among others, in the *Bibliothèque Sacrée* des Pères Richard and Giraud. Paris, 1825, art. 'Confession' and 'Confesseur.'

The box in which the priest sits in the church to hear the penitent is called a confessional. But the act of confession may be performed out of church, in private houses, in the field, in any place in short, provided it be not within hearing of any person except the priest and the penitent.

The Greek church retains the practice of auricular confession, but differs from that of Rome in the form of the absolution. The Protestant and reformed churches, including those of England and Scotland, do not admit the practice, but recommend every one to confess his sins to God, and to repent in order to obtain forgiveness.

Confession is also the name given to the solemn profession of faith of various Christian churches which dissent from that of Rome, such as the Lutheran [AUGSBURG, CONFESSION OF]; that of the reformed churches of France, in 40 articles, signed by Henry, king of Navarre, the prince of Condé, Coligny, and others, and presented to Charles IX. in 1561; that of the Helvetic reformed churches proclaimed in 1566 [ZUINGLI]; that of the churches of the Netherlands, consisting of 37 articles, and published in 1562, afterwards approved and signed by the members of the synod of Embden, in 1571, and lastly examined and confirmed in 1619 by the synod of Dordrecht [ARMINIUS]; and also that of the Protestant churches of Poland, printed in 1570 at Dobrzin, and afterwards approved at the synod of Sendomir.

Some sepulchres of martyrs have been styled by antiquaries confessions; for instance, the subterraneous chapel, in which are the sepulchres of St. Pêter and St. Paul, under St. Peter's at Rome, is called 'the Confession of St. Peter.'

CONFESSION OF AUGSBURG. [AUGSBURG.]

CONFIRMATION is, according to the Church of England, 'the rite of laying on of hands upon those who have been baptized, and are come to years of discretion.' Such only are qualified to be confirmed as can say the Creed, the Lord's Prayer, the Ten Commandments, and the Church Catechism; to the end that children having learned what their godfathers and godmothers promised for them in baptism, they may themselves ratify and confirm the same; acknowledging themselves 'bound to believe and to do' all which those persons undertook for them. It is affirmed in the sixtieth canon of the Anglican church, that confirmation is 'a solemn, antient, and laudable custom in the church of God, continued from the apostolic times.' On the other hand, among the Protestant Dissenters it is regarded merely as the remnant of a Popish ceremony; with the assertion, that there is no more authority for that which is retained of it than for that which is rejected. The passages of scripture which are always adduced in support of this episcopal imposition of hands are the three following; namely, Acts viii. 14-17, Acts xix. 6, and especially Hebr. vi. 1, where ἐπίθεσις χειρῶν, 'the imposition of hands,' appears to be mentioned as an important rite of the Christian religion. But Dissenters disallow this mode of proving the propriety of the imposition of episcopal hands. They deny it to be a legitimate inference from the miraculous act of inspired Apostles to the act of modern bishops. What warrant, they ask, has a bishop to declare that God has given unto an assemblage of several hundreds of individuals 'the forgiveness of all their sins,' because they can say the Church Catechism? (See on this question, Towgood's *Letters on Dissent*; De Laune's *Plea for the Nonconformists*,' &c.) Dr. Whitby observes that, unless the Apostles laid hands on all who were baptized, it makes nothing for confirmation; and that if they did, then Simon Magus received the Holy Ghost. The early fathers certainly believed the Holy Ghost to be indeed conveyed by the imposition of hands. 'When we come out of the water,' says Tertullian (*De Baptismo*, c. 7, 8), 'we are anointed with the holy chrism (perunguimur benedicta unctione), then we have the imposition of hands, which calls down the Holy Ghost (tradit Spiritum Sanctum Paracletum).' *De Resurrec. Carnis*, c. 8; Hieron. *advers. Lucif.*, tom. ii., p. 47; Cyprian, *Epis. 73-74 ad Jub.*, and 72 *ad Steph.*) Confirmation was originally thus administered immediately after baptism, of which it formed the concluding rite or complement, and was called βεβαίωσις; that is, confirmation; nor was there any exception to this time of administering it in the case of baptism in infancy. In the Greek church, and in Asia, it still accompanies baptism. The remonstrance of the Protestants at the Reformation caused the rite to be discontinued to infants, and to be administered only to adults; and afterwards the Council of Trent altered the time for confirmation to the seventh year.

The earliest mention, by the Fathers, of the use of chrism or sacred ointment in confirmation is believed to be in the passage of Tertullian *de Baptismo*, already quoted (Bingham, b. xii., c. 3); but the church of Rome adduces the authority of the Epistle of James, ch. v., v. 14. The anointing the forehead with this holy unction, which was composed of oil and balsam, constituted the first act of the ceremony of confirmation. The consignation, or signing with the sign of the cross, was the second; and the third and last was the imposition of the bishop's hands with the invocation of the Holy Ghost. The person was then qualified to partake of the eucharist. Confirmation in the Greek church is named *μυρὸν*, 'ointment'; *χρίσμα*, 'unction'; *μυρὸν τοῦ χρίσματος*; *σφραγὶς*, 'the seal'; and *ἐπισφράγισμα*. In the Roman church this rite is one of their seven sacraments, and it consists in the bishop's anointing the forehead of the person, saying, 'A. B., I sign thee with the sign of the cross, and confirm thee with the chrism of salvation, in the name of the Father, and of the Son, and of the Holy Ghost.' The bishop then gives a slight blow on the cheek, and concludes with pronouncing the words Pax tecum, 'Peace be with thee.'

Lord King, in his *History of the Primitive Church*, p. 91, has shown that confirmation was originally the same thing as absolution, and that it was frequently repeated on the same individual. On the reiteration of the rite, see also Morinus *de Pœnitentiâ et Ordinatione*, l. 9.

The Puritan contempt for the hierarchy occasioned confirmation to become greatly neglected after the Protestant Reformation in England (Hooker, l. 5, 66; Bishop Hall's χειροθεσία); but subsequent to that period the church of England has observed the rite with much more strictness than the Lutheran or any other church.

Du Pin (*Study of Divinity*, p. 216) gives a numerous list of writers on the subject. (Bingham's *Origines Ecclesiasticæ*, vol. iii., p. 286, *et seq.*; Hammond *de Confirmatione*; Bishop Parker *on Confirmation*; Goar's *Euchologia*, p. 368; Gratian, *Concordantia Discordantium*, part. iii.)

CONFIRMATION (in law). [DEED.]

CONFUCIUS. The real name of Confucius was Koongfoo-tse: the Jesuit missionaries gave it the latinized form in which we use it. According to some authorities, he lived five centuries and a half, and, according to others, only four centuries and a half, before the Christian æra. There is a difference of opinion as to the place of his birth, but that honour is now generally given to the state of Loo, within the district now called Keo-fow Hien, a little to the eastward of the great canal in Shan-tung province, where he was educated, and where he married in the nineteenth year of his age. He was the only son of a woman of illustrious birth. His father, who had several other sons by another wife, held a high government office, but dying some three years after his birth, seems to have left the future philosopher very indifferently provided for. Marvellous stories are told of his love of study when a child, and of his early proficiency in learning and philosophy. The Chinese also record a little fact that may interest phrenologists, namely, that Confucius's head was remarkable for the elevation of its crown. His object in acquiring knowledge was to turn it practically to the purposes of good government, and he accordingly devoted himself exclusively to moral and political science. He divorced his wife after she had borne him a son, 'in order,' say the Jesuits, who excuse this part of his conduct, 'that he might attend to his studies with greater application.' When he thought himself sufficiently qualified to instruct the barbarous age in which he lived, he quitted his solitude for the courts of princes. China was not then united under one emperor: this union did not take place until two or three centuries after the philosopher's death. But when Confucius began his mission, there seem to have been as many independent kings in China as there were in England under the Saxon heptarchy. From the vast extent of the country, each of these states or kingdoms was probably as large as all England put together. The Chinese were not then more pacific than the rest of mankind: the neighbouring states made war upon each other, and every part of the Celestial Empire was in its turn deluged with blood. Not long before the birth of Confucius, the horrors of internal warfare had been augmented by some of the belligerents calling in the foreign aid of the Tartars; but when the philosopher commenced his travels, a powerful international confederacy had been formed, under which the whole of China was comparatively tranquil. He journeyed through these various states in a condition of simplicity and poverty, devoting himself to the instruction of all ranks in his precepts of virtue and social order. His proselytes gradually increased, and he at length reckoned as many as 3000 disciples, of whom 72 were more particularly distinguished by their devotion to their master, and 10 were so well grounded in all sorts of knowledge that they were called, by way of excellence, 'the ten wise men.' In his visits to the different princes he endeavoured to prevail upon them to establish a wise and peaceful administration. His wisdom, his birth, his popularity, recommended him to the patronage of the kings, but his laudable designs were frequently thwarted by envy and interest. After many wanderings and disappointments, he became prime minister, with a recognized authority to carry his theories into practice in his native country Loo. At this time he was 55 years old. In three years he is said to have effected a thorough change in the moral condition of the kingdom. The happiness and prosperity created by the philosophic prime minister excited the jealousy of the neighbouring kings; the sovereign of Loo was soon induced to abandon his benefactor, and Confucius was obliged to flee to the northern parts of China. He was subsequently repulsed at three different courts, to which he applied for office in order that he might render the people happy; and, after sustaining many other sorrows, he withdrew to the kingdom of Chin, where he lived in great poverty. His doctrines, however, had taken root, and it was at this time of adversity that his disciples were most numerous. He went again to Loo, his native country, but vainly solicited to be re-employed in the government.

According to some authorities he enjoyed a few glimpses of royal favour in his latter days, being sought after by the rulers of several states, and employed in high offices, which matured his knowledge and experience: but it seems more certain that his rigid principles, and the firm uncompromising manner in which he carried them into practice, always made him many enemies. His zeal endangered his life more than once, but he regarded death with a stoical eye. At length, full of years, if not of honours, he retired from the world, in company with a few of his chosen disciples, to write or complete those works which became the sacred books of the Chinese, and which have survived twenty-two centuries. He died in his seventy-third year. His sepulchre was raised on the banks of the Soo river, and many of his disciples, repairing to the spot, deplored the loss of their great master. The envy and hatred of his contemporaries soon passed away. When peace was restored, and the empire amalgamated, his writings, which had largely contributed to that happy issue, were looked upon as of paramount authority in all matters; and to mutilate, or in any way to alter their sense, was held to be a crime deserving of condign punishment. Unfortunately, however, the obscurity of the language, and the difficult involved nature of the written character of the Chinese, rendered involuntary alterations and mistakes of the sense numerous and inevitable.

Though Confucius was left to end his life in obscurity, the greatest honours and privileges were heaped upon his descendants, who have existed through sixty-seven or sixty-eight generations, and may be called the only hereditary nobility in China. They flourish in the very district where their great ancestor was born; and in all the revolutions that have occurred their privileges have been respected. In the earlier part of the eighteenth century, under the great emperor Kang-hy, the total number of descendants amounted to eleven thousand males. In every city, down to those of the third rank, styled Hien, there is a temple, dedicated to Confucius. The mandarins, all the learned of the land, the emperor himself, are bound to do him service. This service consists in burning scented gums, frankincense, tapers of sandal-wood, &c., and in placing fruit, wine, flowers, and other agreeable objects before a plain tablet, on which is inscribed,—'O Confucius, our revered master, let thy spiritual part descend and be pleased with this our respect, which we now humbly offer to thee.' The ceremony is precisely the same as that which every man is enjoined to observe in the hall of ancestors to his parents, &c.

'It was the great object of Confucius,' says a recent writer, 'to regulate the manners of the people. He thought outward decorum the true emblem of excellence of heart: he therefore digested all the various ceremonies into one general code of rites, which was called Le-ke, or Ly-king, &c. In this work every ritual in all the relations of human life is strictly regulated, so that a true Chinese is a perfect automaton, put in motion by the regulations of the Ly-king. Some of the rites are most excellent: the duties towards parents, the respect due to superiors, the decorum in the behaviour of common life, &c., speak highly in favour of Confucius; but his substituting ceremony for simplicity and true politeness is unpardonable. The Ly-king contains many excellent maxims, and inculcates morality, but it has come to us in a mutilated state, with many interpolations.' (Gutzlaff, *Sketch of Chinese History, antient and modern.*)

In the writings of Confucius the duties of husbands towards their wives were slightly dwelt upon. On the other hand, the duties and implicit submission of children to their parents were extended to the utmost, and most rigidly inculcated. Upon this wide principle of filial obedience the whole of his system, moral and political, is founded. A family is the prototype of his nation; and, instead of the notions of independence and equality among men, he enforces the principles of dependence and subordination—as of children to parents, the younger to the elder. (Dr. Morrison.) By an easy fiction, the emperor stands as the father of all his subjects, and is thus entitled to their passive obedience; and, as Dr. Morrison observes, it is *probably* (he might say *certainly*) this feature of his doctrines which has made Confucius such a favourite with all the *governments* of China, whether of native or Tartar origin, for so many centuries. At the same time it should be observed that this fundamental doctrine has rendered the Chinese *people* slavish, deceitful, and pusillanimous, and has fostered the growth of a national character that cannot be redeemed by gentleness of deportment and orderliness of conduct.

Confucius was a teacher of morals, but not the founder of a religion. His doctrines constitute rather a system of philosophy in the department of morals and politics than any particular religious faith. (Davis.) Arnauld and other writers have broadly asserted that he did not recognise the existence of a God. (Bayle, *Philos. Dict.*, in art. 'Maldonat'). In his physics Confucius maintains, that 'out of nothing there cannot possibly be produced anything; that material bodies must have existed from all eternity; that the cause (*lee*, reason) or principle of things must have had a co-existence with the things themselves; that, therefore, this cause is also eternal, infinite, indestructible, without limits, omnipotent, and omnipresent: that the central point of influence (*strength*) whence this cause principally acts, is the blue firmament (*Tien*), whence its emanations spread over the whole universe; that it is, therefore, the supreme duty of the prince, in the name of his subjects, to present offerings to *Tien*, and particularly at the equinoxes; the one for obtaining a propitious seed-time, and the other a plentiful harvest.' He taught his disciples that the human body is composed of two principles,—the one light, invisible, and ascending; the other gross, palpable, and descending: that on the separation of these two principles the light and spiritual part ascends into the air, whilst the heavy and corporeal part sinks into the earth. The word *death* never enters into his philosophy; nor, on common occasions, is it employed by the Chinese. (Barrow.) When a person dies they say, 'he has returned to his family.' The body, it was difficult to deny, resolved itself into its primitive elements, and became a part of the universe; but, according to Confucius, the spirits of the good were permitted to visit their antient habitations on earth, or such ancestral halls or other places as might be appointed by their children and descendants, upon whom, while they received their homage, they (the dead) had the power of conferring benefactions. Hence arose the indispensable duty of performing sacred rites in the hall or temple of ancestors; and all such as neglected this duty would be punished, after death, by their spiritual part being deprived of the privilege of visiting the hall of ancestors, and of the supreme bliss arising from the homage bestowed by descendants. A belief in good and evil genii, and of tutelar spirits presiding over families, houses, towns, and other places, inevitably arose out of this system. It does not appear however that either Confucius or any of his followers attached the idea of a *personal being or form* to the Deity; nor have the true Confucians ever represented the *Great First Cause* under any image or personification whatsoever. The images and idols of China belong to other faiths. It was soon found that the notions of Confucius were too abstract and ideal for the mass of his countrymen; who, like the rest of mankind in nearly all ages and all countries, required something material to fix their attention and excite their devotion.

The moral doctrines of Confucius include that capital one, which, however neglected in practice, has obtained, in theory, the universal assent of mankind: he taught his disciples 'to treat others according to the treatment which they themselves would desire at their hands.' In his doctrines there is an evident leaning to predestination or fatalism, and to fortune-telling, or predicting events by the mystical lines of Fo-shee. With all his defects and omissions, Confucius was, however, a most wonderful man. His system, without making any pretension to a divine legation, still continues to prevail throughout the most extensive empire in the world. Some religions may have lasted as long, or longer, but we believe no philosophic code can claim anything like such a lengthened period of active practical existence. The Tibetan, the Buddhist, and other religions, have divided and still divide influence with it, but have never overthrown its empire. The superstitious and the vulgar of all classes, from the emperor on the throne to the poor sailor on board the junk, may burn gilt paper and offer sacrifices to wooden idols, practise incantations, and offer up prayers to the 'invisible mother of heaven,' but at the same time they all revere the name of Confucius, and the more enlightened pretend to be wholly guided by his merely philosophical code. The body of his laws and instructions is still followed, not only by the Chinese, but by Coreans, Cochin-Chinese, and other people who, taken collectively, are estimated at 400,000,000 of souls.

The classical or sacred works written and compiled by Confucius and his disciples, are nine in number; that is to say, the 'Four Books' and the 'Five Canonical Books.' The first of the Four Books is the *Ta-heo*, or 'The School of Adults;' the second the *Choong-yoong*, or 'Infallible Medium;' the third the *Lun-yu*, consisting of the conversations and sayings of Confucius, recorded by his disciples, and which, according to Mr. Davis, is 'in all respects a complete Chinese *Boswell*;' and the fourth the *Meng-tse*, which contains the additions and commentary of *Meng-tse*, or Mencius, as he is called by Europeans, who lived about a century after Confucius. The Five Canonical Books, all said to be written or compiled by Confucius himself, are, the *Shy-king*, or Book of Sacred Songs; the *Shoo-king*, which is a history of the deliberations between the antient sovereigns of China; the *Ly-king*, or Book of Rites and Ceremonies, which is considered as the foundation of the present state of Chinese manners, and one of the causes of their uniform unchangeableness; and lastly, the *Chun-tsieu*, which is a history of the philosopher's own times, and of those which immediately preceded him. (J. F. Davis—*The Chinese; a General Description of China and its Inhabitants*, London, 1836; Gutzlaff—*Sketch of Chinese History, antient and modern*; *Travels of the Jesuit Missionaries*, Bell (of Antermony), Barrow, Staunton, &c.)

CONGE' D'ESLIRE, a term in Norman French, literally signifying 'leave to elect,' which is appropriated to the king's writ or license to a dean and chapter to elect a bishop, at the time of the vacancy of the see. The right of nominating to bishoprics was in most countries of Europe enjoyed by the temporal sovereigns, with little opposition from the ecclesiastical authorities, until the eleventh century, when a contest began between the popes and the monarchs of Europe, which, in the next century, ended in the latter being compelled to surrender this important privilege to the clergy. Father Paul (*Treatise of Benefices*, c. 24), says that between A. D. 1122 and A. D. 1145, it became a rule almost everywhere established, that bishops should be chosen by the chapter. In England, by the constitutions of Clarendon, A. D. 1164, the election was vested in the chapters, subject to the king's approbation of the object of their choice. The right of election was afterwards formally surrendered to the chapters by a charter of King John, by which however he reserved to himself, among other things, the right of granting a congé d'eslire, and of confirming the choice of the chapter. This grant of freedom of election was expressly recognised in Magna Charta, and also by a subsequent statute, 25 Ed. III., stat. 6, which was passed for the purpose of preventing the popes from interfering with the elections to dignities and benefices in England.

So the law stood until the passing of 25 Henry VIII., c. 20, which, though repealed in Edward the VI.th's reign, was afterwards revived, and by which episcopal elections are regulated at the present day. By this Act it is provided that upon every avoidance of an archbishopric or bishopric the king may grant to the dean and chapter a license under the great seal to proceed to the election of a successor, and with the license a letter missive containing the name of the person whom they are to elect. If the dean and chapter delay their election above twelve days after receiving the license, the king may, by letters patent, nominate any person whom he pleases to the vacant see; if they delay the election beyond twenty days, or elect any other person than the candidate recommended by the king, or do anything else in contravention of the Act, they incur the penalties of a præmunire. Bishoprics in Ireland are donative by letters patent, without a congé d'eslire. (*Irish Stat.*, 2 Eliz., c. 4.)

CONGER. [MURÆNIDÆ.]

CONGESTION, a preternatural accumulation of blood in the capillary vessels of the sanguiferous system, attended with disordered function of the organs in which such an accumulation takes place. It has been shown [ARTERY, CAPILLARY, CIRCULATION,] that the main functions of the sanguiferous system are performed by the ultimate divisions of the blood-vessels, called, from their hair-like minuteness, *capillaries*; the office of the main trunks and the larger branches of the blood-vessels being merely to convey to the capillaries the material acted upon by them in the various processes which they perform. In the natural and healthy state of an organ, the arterial capillaries in which the arterial trunks that supply it with arterial blood terminate, receive a certain quantity of blood; retain that blood a given time; and then transmit it with a given impetus into the venous capillaries, which in their turn convey it into the larger venous branches, and these to the heart with a given degree of velocity. Upon this transmission of the blood to and from the organs in a given quantity and a given time, depends the balance of the circulation; upon the due balance of the circulation depends the healthy condition of the organic processes; and upon the healthy condition of the organic processes depends the sound performance of the animal functions.

Of the mode in which the balance of the circulation is disturbed by the preternatural accumulation of blood in the capillary vessels, some conception may be formed by observing the phenomena that take place when a mechanical or chemical irritant is applied to a transparent part of the animal body; and when such a part is brought under the field of the microscope, so that the circulation in the minute vessels can be distinctly seen. In this case, the first phenomenon observable is a quickened circulation in the part, and the consequent determination to it of a greater quantity of blood; next, after a time, the blood-vessels are seen to dilate and to become turgid with blood; and in the third place, the flow of blood through these distended vessels is manifestly retarded; and ultimately, if the irritating cause continue to operate with a certain degree of intensity, the circulation is wholly stopped. The quickened circulation, the first phenomenon that takes place, is occasioned by the action of the contractile power inherent in the coats of the capillary vessels, excited in an inordinate degree by the application of the unusual stimulus. The dilatation of the capillary vessels, the subsequent event, arises from a diminution of the vital power of the coats of the vessels, from the over-excitement produced by the irritating cause

The blood-vessels in this state are commonly said to have lost their tone; to be debilitated or weakened. The consequences of this loss of vital power in the living tissues that form the walls of the blood-vessels, are the engorgement of the vessels, the impeded, retarded, or abolished circulation of blood through them, and the disordered or suspended function of the part affected.

From the preceding statement, a distinct conception may be formed of that morbid condition of the blood-vessels, to the designation of which the term congestion is commonly applied. How greatly such a condition of the blood-vessels must disturb their natural functions, and consequently how powerful an agent it must be in the production of disease, it is also easy to conceive. But pathologists have hitherto made but slight progress in determining with precision the nature of the morbid changes which take place, either in the blood-vessels themselves, or in the tissues in which, as a consequence of this affection, an alteration of structure is sometimes ultimately superinduced.

From an observation of the phenomena connected with the state of congestion, it is usually distinguished into passive and active. When there is merely an accumulation of blood in the distended and debilitated capillaries, without any other manifest morbid phenomenon, the state is called simple congestion; and this state of congestion is commonly said to be passive. But when to this accumulation of blood there are superadded certain phenomena which accompany and which characterize another morbid state, namely, inflammation, the congestion is termed active. In active congestion, the blood-vessels themselves are in a state of excitement; the preternatural quantity of blood they contain is determined to them by their own inordinate activity; they are in a condition not of diminished but of exalted vital energy. In passive congestion, on the contrary, the coats of the vessels are destitute of their natural tonic, vital resistance; yield readily to the current of blood which is determined to them, or unable to pass on the current they receive, the blood accumulates in them and distends them. Active congestion, according to this account, however, can be distinguished by no certain and even no appreciable character from inflammation, a state which is always supposed to be different from congestion. It is certain that the state of congestion has a peculiar tendency to pass into the different state of inflammation, and it is this very tendency that renders congestion so dangerous and fatal a malady. But in what the two states differ, we are at present wholly ignorant. When the link that connects these two states with each other shall be supplied, a clear and bright light will be shed over the nature of some of the most important diseases at present involved in profound darkness. The labours of pathologists, conducted as they now are, with a precision and skill never before exemplified, should be sustained and animated by the prospect of the inestimable practical advantages which must result from the success of their investigations.

The tissue of the body in which the state of congestion is most apt to occur, is the cellular, and more especially in the lax and little cohesive condition in which this tissue forms the parenchyma of the different internal organs, as the brain, the lungs, the liver, the spleen, the kidneys, and so on. A congested state of their blood-vessels is also peculiarly apt to occur in the mucous membranes, and more especially in the mucous membranes of the bronchi and air vesicles of the stomach and the alimentary canal, and of the ovaria and uterus. But besides these, other and less yielding structures, as the serous and fibrous membranes, the skin, and even the muscles, may be affected with congestion, after the operation of causes which have exhausted the vital energies of the system in general, or which have diminished the vital cohesion of these structures in particular.

Congestion, when present to any considerable extent, and when continuing for any length of time, disorders the function of the organ in which it takes place. The signs of this disordered function are signs from which it is inferred that congestion is present. If, for example, the blood-vessels of the brain be in a state of congestion, the activity and energy of the cerebral functions will be diminished, indicated by dulness, heaviness, forgetfulness, inaptitude for mental labour, giddiness, lethargy, and so on: and if the congestion be in great intensity, it may produce all the symptoms of coma and even of apoplexy. [COMA and APOPLEXY.] If the blood-vessels of the liver be in a state of congestion, the secretion of bile will be disordered; altered in quality, diminished in quantity, or entirely suppressed. If the blood-vessels of the mucous membrane of the air passages be in a state of congestion, it will occasion uneasiness in the chest, difficulty of breathing, cough, &c.

Congested states of these and other organs are exceedingly apt to occur in the progress of other diseases, more especially in the different types of fever, the character of which they modify, and the severity and danger of which they always greatly increase. There are fevers indeed, and those of the very worst kind, that is, the most intense and the least under the control of any known remedies, in which a high degree of congestion of the blood-vessels of the brain, of the lungs, of the liver, or of the mucous membrane of the intestines, is among the very first appreciable morbid conditions of the system; but in general such a congested state of the blood-vessels is consequent upon preceding morbid conditions of the organs; conditions by which the vital energies of the blood-vessels have been exhausted.

The appearances presented by congested parts after death, vary with their structure and with the degree and duration of the affection. The capillary arteries and veins are turgid with blood; the blood they contain is of a darker colour than natural; hence the colour of the organ, the seat of the congestion, is darker in proportion to the intensity of the affection; it is also commonly more or less swollen, and the cohesion of its tissues is diminished, so that they are more readily torn than when in a healthy condition. In some organs, indeed, as in the liver and the spleen, when the congestion is in an extreme degree, the cohesion of the component tissues is so much lessened that the organs are broken down on the slightest pressure.

Anything may be the cause of congestion which diminishes the vital energy of the capillary vessels; or which changes, beyond a certain limit, the quantity and quality of the blood they contain. If the vital energy of the capillaries be diminished, they cannot maintain the tension necessary to prevent distension of their parietes, and a consequent preternatural accumulation of blood. If the quantity and quality of the blood they contain be altered, their natural stimulus may be so deficient as not to excite, or so excessive as to exhaust them.

There is no morbid state of the system over which human art has so little control as that of congestion when the affection is extensive and severe. When, however, it is seated only in a single organ, and is not very intense, there are remedies which have a powerful tendency to relieve it; but there is scarcely any disease of the body the treatment of which requires to be conducted with so much caution and discrimination. The adoption of a wrong course, or the too vigorous application of a well-chosen remedy, has, in this case, a more than ordinary tendency to turn the balance between life and death, on the side of death. If the congestion be what is termed active, general blood-letting is sometimes indispensable; on the other hand, there are many cases of passive congestion, in which the abstraction of blood from the system in the smallest quantity, would be certain to extinguish life. In cases in which general depletion would be pregnant with danger, local blood-letting is often safe, and when employed with cautious decision, is the most efficient of all remedies. Its effect is sometimes greatly promoted by external local derivatives, as blisters, and by internal remedies which tend at once to stimulate the heart's action and to equalize the circulation, such as what are termed the diffusible stimulants, and diaphoretics. Emetics and purgatives are also auxiliary remedies, in general safe, and often remarkably efficient.

CONGLETON, a market town and borough in the county of Cheshire. It is in the parish of Astbury, in the eastern extremity of the hundred of Northwich, on the Staffordshire border; 42 miles nearly due east from Chester, in a straight line, and 162 N. N. W. from London. It appears to be a place of great antiquity, and is supposed to have been a military station of the Romans. The present town is a mile in length, and contains many of the antient houses of Cheshire, which are constructed entirely of timber frame-work and plaster. It is beautifully situated in a deep and picturesque valley on the banks of the river Dane. At the west end are numerous detached mansions of the opulent manufacturers of the place, surrounded with shrubberies and ornamental gardens. In the antient part is the guildhall, a commodious brick building, with a piazza for those who attend the market. The general appearance of the town is neat and respectable, and it bears a character for remarkable healthiness. The Macclesfield canal, and the great road from Lichfield and Stafford to Manchester, pass through it. The population in 1831 was 9352, of whom 4474 were males, and 4878 females. At this time there were 27 families employed in agriculture, and 1644 families employed in the silk manufacture, which of late years has greatly increased. The silk-mills erected on the banks of the river are very extensive. Ormerod, in his history of Cheshire, speaks of twenty-eight in the year 1819, for ribands and other kinds of silk fabric (vol. iii. p. 20). The manufacture of Congleton is almost wholly confined to black silks. In thrown-silks it exceeds the manufacture of Macclesfield, though in fancy-silks, and in the whole amount of business, it is much inferior. It is observed in the 'Report on the Municipal Corporations' (1835), that no new works have been erected since 1825, and that the state of the manufacture is not such as to offer encouragement to any additional speculations. It is added that the silk goods are greatly exposed to depredations; detection being difficult in consequence of the smallness of the bulk in proportion to the value. There is no cotton manufactory within the boundary of the borough, but there are several immediately beyond it. There are also some tanneries and manufactures of leather. This town was formerly celebrated for tagged leather laces, called Congleton points. The borough of Congleton is co-extensive with the township of Congleton, which is one of several constituting the parish of Astbury. It is divided into three wards, with six aldermen and eighteen councillors. The living is a perpetual curacy subordinate to the rectory of Astbury; but though the chapelry extends over an area of 2500 acres, the stipend is only about 140*l.* a year. The dissenting chapels are numerously attended, including one of Catholics. The Methodists and Independents have schools each, with several hundred scholars. There is a free grammar-school, with sixty-eight scholars, who are taught Latin and Greek; also several Sunday-schools, an infant-school, and several endowed charities. The licensed public-houses are very numerous—there are 50, and 52 beer-shops within the space of 300 yards. (*Municipal Corp. Rep.*, p. 2657, part 4.) The market-day is on Saturday; and fairs are held on Thursday before Shrovetide, May 12, July 5, and November 22, for cattle and pedlars' wares. (*Boundary Report; Municipal Corp. Report; Population Report; Report on Charities;* Lysons' *Mag. Brit.*; Ormerod's *Cheshire*.)

CONGLOMERATE, the generic term for coarse sand or rounded fragments of stone, of various kinds, cemented into a mass. It is sometimes called pudding-stone. Conglomerates differ in their nature, and vary in the size of their component parts according to the process by which they have been brought into the form of conglomerate. The mechanical convulsions of the earth, great floods, and other agents, more or less powerful, having carried the primary materials into places favourable to the process, and rubbed off their sharp and angular parts, they are united into solid masses by a posterior formation. Along the base of the Maritime Alps the rivers, with few exceptions, are now forming conglomerate and sand. (Lyell's *Geology*). Near Nice the mud, pebbles, and portions of rock brought down by the torrents form beds of shingle; but the greater part are swept into the deep sea, where they form strata of inclined conglomerate, about 1000 feet in thickness and seven or eight miles in length. Volcanic eruptions also tend to the formation of conglomerate by uniting masses of rock together. Conglomerates, as already observed, to whatever causes owing, are characterized by being manifestly a congeries of fragments of rock, of various sizes, which have undergone the process of attrition, and consequently have been formed by fragments of various rocks that have been carried considerable distances. [BRECCIA.] Many of these conglomerates are sometimes so well compacted as to form a hard rock, capable of receiving a considerable degree of polish, as we observe in two colossal fragments of heads in the British Museum, the faces of which are tolerably smoothed by Egyptian art, while the broken parts exhibit a conglomerate consisting of irregular-sized rounded grains, and masses of quartz and other rocks.

CONGO. This name, in its most extensive application, as explained under the word ANGOLA, comprehends the whole of the region lying along the western coast of Africa, which is more correctly divided into the four kingdoms or districts of Loango, Congo Proper, Angola, and Benguela. In this large and loose sense it extends from Cape Lopez Gonsalvo, in lat. 0° 44′ S., to Cape Negro, in lat. 15° 40′ S. Congo, properly so called, however, at least according to its modern limits, (for it is said to have been more extensive formerly,) does not stretch to the north beyond the river Zaire (otherwise called the Congo), in about lat. 6° S., which separates it from Loango, nor to the south beyond the river Dando, in lat. 8° 20′ S., which separates it from Angola. It is believed to extend a considerable distance into the interior; but we have no distinct information respecting its limits in that direction, and they are probably not very definitely marked. The country immediately to the east of Congo appears to be that of the Giagas, a race of bushmen whose ferocity is much dwelt upon in the old accounts, and seems to be still the terror of their more peaceable neighbours.

The first European who reached Congo was the Portuguese navigator, Diogo Cam, who made his way thither from Elmina, in 1484. Diogo revisited the country in 1489, making his voyage on that occasion from Portugal. The following year another armament arrived from Portugal, under the command of Ruy de Souza. After this the king of Congo, and many of his subjects, made profession of Christianity, and the Portuguese formed considerable establishments in the country. It was in the course of the seventeenth century, however, that the most strenuous endeavours were made in the work of converting the natives. Ample accounts of the proceedings of the Portuguese missionaries, of the opposition and difficulties of various kinds they had to contend with, and of the wonderful success which, notwithstanding, is asserted to have crowned their persevering labours, are given in the Voyage of Michel Angelo di Gattina and Dionisio Carli di Piacenzo, two Capuchin friars, who set out to join the mission in Congo in 1666; and in that of Geronimo Merolla di Sorrento, another Capuchin father, who joined the same mission in 1682. There are French and English translations of both these voyages, which were originally published in Italian; and they are incorporated in Labat's 'Relation Historique de l'Ethiopie Occidentale,' 5 vols., 12mo. Paris, 1732; along with a translation, also from the Italian, of Father Cavazzi de Montecucculo's description of the kingdoms of Congo, Angola, and Matamba. A relation of the earlier attempts to christianize the people of Congo, beginning with the first introduction of Christianity into the country, may be found in an account of Congo and the neighbouring countries, first drawn up in Italian, in 1589, by Filippo Pigafetta, from the journals and verbal information of Duarte Lopez, a Portuguese captain, who had spent about ten years in Congo, and was eventually sent to Madrid and Rome, on a sort of embassy from the king, for priests, missionaries, and warlike assistance against his enemies. Pigafetta's book was early translated into English and Latin.

The earliest English account of Congo is that published by Purchas under the title of 'the Strange Adventures of Andrew Battel, of Leigh, in Essex, sent by the Portuguese prisoner to Angola, in which kingdom and the adjacent regions he lived eighteen years.' Battel, whose relation is very curious, was detained in this part of Africa from 1589 till 1607. An English navigator, of French descent, James Barbot the younger (so called to distinguish him from his father of the same name, also a writer of voyages), made a voyage to Congo in 1688, the journal of which was published along with the voyages of his uncle, John Barbot. There are translations or abstracts of all these early voyages in the 4th and 5th volumes of Prevost's 'Histoire Générale des Voyages.' Some of them are also in Hackluyt and Purchas; and most of them in Churchill, Harris, Osborne, Pinkerton, and the other English collections. In Labat's book, already mentioned, the accounts of several Portuguese voyagers are added to those of the missionaries. The country is also described, from personal acquaintance, in Olfert Dapper's 'Description of Africa,' first published in Dutch, at Amsterdam, in 1670, but of which there is a French translation, fol. Amst., 1686. The Abbé Proyart has collected the most important particulars mentioned in these voyages in his 'Histoire de Loango, Cacongo, et autres Royaumes d'Afrique,' 1776, of which there is an English translation in the 16th vol. of Pinkerton's collection, pp. 548—598.

According to the old accounts, the native division of Congo is into the six provinces of Bamba, Sogno (or Sonio), Sondi, Pango, Batta, and Penda. The Portuguese however appear to have divided the country into what they called the metropolitan province of San Salvador, the duchy of Bamba, the duchy of Sondi, the marquisate of Pemba, and the county (or earldom) of Sogno, thus omitting altogether Pango and Batta, or comprehending them under some of the other names. The Portuguese province of San Salvador is a part of the native province of Pemba, the marquisate of Pemba being the remainder. It is placed along a portion of the left bank of the river Congo, immediately to the north-east of Sogno, which occupies the angle formed by the river and the sea-coast. In this province is the capital, said to have been antiently called Banza, which appears however to be merely a name signifying a chief town, the residence of a king, or even of a subordinate ruler. The Portuguese having established a settlement here, gave the place the name of San Salvador. It is described as situated about 150 miles from the sea, and about a third of that distance from the river, in a hollow on the south-east side of a lofty mountain, having on the summit a plain of about ten miles in circuit, which is covered with towns and villages. The palace of the native sovereign and the Portuguese part of the town are each surrounded by an inclosure of about a mile in circumference; but the suburbs of the Portuguese town are described as also of considerable extent. The principal ornaments of San Salvador were, a cathedral and nine or ten other churches, all built of stone, although, with the exception of that of the Jesuits, roofed only with thatch. The religious establishment consisted of a bishop and chapter, a Jesuit college, a convent of capuchins, &c. It appears however that even before the end of the seventeenth century the ravages of war had almost ruined San Salvador, and the native sovereign had transferred his residence to another place, called Lemba, in the province of Bamba, and nearer the sea-coast.

For details as to the history, the religion, the customs, the arts, and the former general condition of the people of Congo, we must refer the reader to the missionary accounts, in which these matters are treated at great length. There is probably however a good deal of fiction in these accounts, the prevailing aim of which evidently is to exaggerate the importance of the country and its inhabitants. At all events, now that both the show of Christianity and the very thin sprinkling of civilization, of which this region of Africa may at one time have had to boast, have nearly disappeared, these old descriptions would certainly be found very inapplicable to the present state of Congo.

The most authentic information we possess respecting the modern state of Congo, is derived from the 'Narrative of an Expedition (sent out by the English government) to explore the river Zaire, usually called the Congo, in 1816, under the direction of Captain J. K. Tuckey, R. N.,' 4to., London, 1818. Captain Tuckey and his companions, of whom out of 56, the whole number, no fewer than 21 perished in this disastrous expedition, including Tuckey himself, and all the scientific persons whom he took along with him, made their way up the river to a point about 280 miles from its mouth; and in the course of their navigation they both saw and conversed with many of the natives, and made some excursions a short way into the interior of Congo. Their actual inspection of the country however was of course confined to the portion along the bank of the river; and the only record we have of the information they obtained, consists of the journals of Captain Tuckey and Professor Smith, the botanist attached to the expedition, hastily drawn up at the time, and which the writers had no opportunity of revising and extending at leisure. Their account therefore can scarcely be safely assumed as applicable to more than a very small part of the whole region comprehended under the name of Congo. It is, in fact, principally an account of the lower part of the great river up which the expedition sailed.

The Congo, even till of late years, was supposed by some persons to be the embouchure of the Niger; but long before this point was settled, the soundest geographers were of a different opinion, although Captain Tuckey's expedition was undertaken with the view of ascertaining the matter; and in the official account of the voyage, the identity of the two rivers is elaborately contended for by a writer, who declares that 'the hypothesis which makes the Niger to pour its waters into the gulf of Benin is entitled to very little attention.' The Congo is not properly called the Zaire, it seems, as Diogo Cam was led to suppose, that being merely a word signifying any great river, but the Moienzi Enzaddi, which means the river that swallows up all other rivers. The old accounts represent the velocity with which it rushes into the sea to be so great, that it preserves its stream unaffected by the salt water for twenty leagues or more. This description Captain Tuckey found reason to believe considerably exaggerated. It had been usually stated that the Congo was always full of water; but when he entered it, in the beginning of July, he found it from eight to eleven feet lower than the point which from the marks on the rocky banks it appeared to have reached at other seasons. The tide also was very perceptible at 140 miles up the river. The velocity of the current at the mouth of the river was found nowhere to exceed 4½ or 5 knots an hour, and in many places it was not more than 2½. The accounts of some preceding navigators make it flow at the rate of six or seven knots; and so it very possibly may do, when the channel is more full of water. The depth however in the middle of the stream here was very great, no bottom having been found with a line of 160 fathoms; so that when the river is at high flood the mass of water which it pours forth must be immense. Its breadth for some distance from the sea is not less than five or six miles; it is then divided by a number of islands into several streams: at the distance of 140 miles from the mouth the Narrows commence, and continue for about 40 miles, during which it forces its way between two opposite barriers of steep rocks, not more than from 300 to 500 yards asunder. Many ledges of rocks stretch across this part of the river, the most formidable of which however, called the Great Yellala, or Cataract, has only a fall of about 30 feet in 300 yards, and would be more appropriately designated by the term Rapid. Above the Narrows, which terminate at a place called Inga, the river expands to the breadth of two, three, and even four miles. Tuckey ascended it for about 100 miles beyond this point, and he was assured by the natives that after this there was no impediment to its continued navigation for a great distance. Its direction, according to their account, continued to be nearly in a straight line towards the north-east; and Tuckey appears to have felt convinced that it must have its source in some vast lake or chain of lakes several degrees to the north of the equator. Much surprise was experienced at finding that it did not receive the water of any other stream in the whole distance along which the survey extended; and both Captain Tuckey and Professor Smith were inclined to believe that it must receive accessions of water by some underground communication. The old delineations of the river, it is to be observed, also represent it as without any tributaries in this part of its course; but they make numerous rivers to flow into it higher up. The torrents that pour down in the rainy season however through the ravines between the hills on both sides of it, probably bring it a considerable supply. In the lower part of its course the Congo spreads out into extensive swamps, which are covered with mangrove and palm trees, as are also the islets by which it is here interrupted; above the swampy region, hills, none of which much exceed 2000 feet, rise all the way that the survey extended at a short distance from the channel, or the rocks between which it is confined. Up to the great cataract of Yellala these hills are stony and nearly barren, and the rocks at the Narrows are composed of masses of micaceous slate; but beyond this point the rocks are of limestone, and the country is described as fertile and beautiful. Even below this however, between the hills and the water, vegetation is in many parts very luxuriant, and numerous villages are to be seen both in the hollows and even on the flat summits of the mountains. The old maps make five or six smaller rivers fall into the sea between the Congo and the Dando.

With regard to the products of Congo, the information acquired by this expedition accords sufficiently with the accounts of the Portuguese missionaries. Although so many of the members of the expedition were cut off by a fever, which appears to have been brought on by fatigue and exposure to the night air, and to have been of a contagious character, the climate of Congo is described as neither disagreeable nor in ordinary circumstances unhealthy. The range of the thermometer in a period of a month, from about the middle of July to the middle of August, was never below 60° during the night, nor above 80° during the day; the common noon-day heat was 76°. Among the vegetable products (for many of which the natives must have been indebted to the Portuguese) are manioc or cassava, yams, maize, sweet potatoes, pumpkins, millet, calavanses, cabbages, spinach, pepper, capsicum, the sugar-cane, and tobacco. Of fruits they have the banana, the papaw, the orange, the lime, and the pine-apple, which last Captain Tuckey found growing in the open places at the extreme point to which he penetrated. If, as is supposed, the pine-apple be indigenous only in the New World, the plants must have been carried thither by the natives, for certainly no European settlements had ever been formed so far from the sea-coast. Their only prepared beverage is a wine made from the juice of the palm-tree, which was found by the members of the expedition to be both an agreeable and a wholesome drink. Of domestic animals there are goats, hogs, fowls, ducks, and pigeons, as well as a few hairy sheep. There were also some horned cattle, to which however little attention seemed to be paid; no beasts of burthen were seen. Of wild animals, the country abounds with elephants, leopards, lions, buffaloes, large monkeys, antelopes, wild hogs, &c. Guinea fowl and red-legged partridges are described as abundant, large, and fine, and wild pigeons, of three or four species, as very plentiful. Bees are in great numbers; the flea and the bug were the only insects that were found troublesome. The lower part of the river abounds in different species of fish, which form an important part of the subsistence of the people; it also, especially above the Narrows, swarms with hippopotami and crocodiles.

The native sovereign of Congo, Captain Tuckey was informed, was called Lindy, or Blindy N'Congo, and resided at a place called Banza Congo, six days' journey southward from the river. This is, in all probability, the San Salvador of the Portuguese, who were affirmed by the natives to have soldiers and white women there. Under the king are the Chenoos. 'The Chenooships,' says Captain Tuckey, 'improperly named kingdoms by Europeans, are hereditary fiefs, passing in the female line, that is, on the decease of the Chenoo the succession, instead of passing to his son, goes to his brother, or uterine uncle or cousin.' In other words, to secure the certainty of the blood royal, the successor must descend from the same female ancestor with the deceased chief, and must be the nearest male descended, either immediately or through a line of females, from that common female ancestor. Of the inferior officers, the chief is the Mafook, or collector of the customs, who is generally qualified to act as an interpreter to the European visitors of the coast. These functionaries also often amass considerable wealth by giving their services as agents to the slave traders, Portuguese and piratical, who still resort to Congo. A place called Embomma, on the north bank of the river, and about fifty miles from its mouth, appears to be the great slave mart. It may be observed that Captain Tuckey represents the dominions of Congo as comprehending a small territory to the north of the river included within a line drawn from below Malembo, a town on the sea coast about fifty miles north from the mouth of the river, to Banza N'Inga at the termination of the Narrows.

The natives of Congo, although they have thus an established government, and have arrived at the agricultural state, cultivating regularly two crops of Indian corn in the year, must be considered as sunk in the same barbarism with the other nations of the west coast of Africa. Rights of property are well understood among them, and are carried so far that a fowl or a pig will sometimes have three or four proprietors. But their houses are mere huts constructed of a few posts stuck in the ground and interwoven with reeds, and they go naked, with the exception of a small apron, generally of grass-matting, tied round their loins. They seem to be a timid and unwarlike race, and both their indolence and their sensuality are extreme. Their women are their drudges in all kinds of laborious work, and, not excepting the sisters, daughters, and wives of the highest personages, are eagerly offered by them for a trifle to a white man of any grade. Their sense of the whites being a race of beings altogether distinct from themselves seems to be complete. They scarcely appear to have gained a step towards civilization by their intercourse with the Portuguese. Even the Christianity introduced among them by their European conquerors has, as in such circumstances might be expected, retained very little resemblance to what is commonly understood by that name. Captain Tuckey was visited, when near the coast, by a Christian priest, who had been taught to write his own name and that of Saint Antonio, and could even read the Romish litany in Latin, but who boasted that he had a wife and five concubines, and stoutly maintained that this kind of polygamy was not at all prohibited in the New Testament. Both this man and the other Christians, as they called themselves, who came along with him, were tattooed all over like the rest of the natives, and had the two upper front teeth filed away, in deference to the prevalent notion of beauty in Congo.

It is a curious circumstance that the language of Congo, which is merely a dialect of that of Angola, Benguela, and the other neighbouring districts, appears to be also radically the same with that spoken by the natives of the east coast of Africa, which is separated by thirty degrees of longitude from the coast of Congo. This fact was first noticed by the late Mr. Marsden (the author of the 'History of Sumatra,'), and has been confirmed by the lists of Congo words collected by Captain Tuckey.

Since the publication of Captain Tuckey's Voyage, an account of a visit to Congo and the neighbouring countries, by M. Douville, has appeared in the transactions of the French Geographical Society. This voyage, unfortunately for those who profess to be geographers and have given credit to it, turns out to be the fiction of an ignorant and unprincipled adventurer. Douville afterwards published a separate book, with plates. The plates on the face of them are good for nothing.

CONGREGATION most commonly signifies an assembly of persons for the purpose of public worship and religious edification. It denotes more particularly a number of ecclesiastics constituting a legislative and executive body; and in this acceptation it is applied chiefly to certain Boards of administration consisting of cardinals and of prelates, or aspirants to the cardinalship in Rome. These congregations serve as a check on the papal authority: for though their proceedings are usually sanctioned by the pope, he cannot, without alleging the weightiest reasons, put a veto on them. The whole number of these congregations is twenty-one that is, fifteen for spiritual and six for temporal purposes. Congregation is also used to designate a company, society, or fraternity of monks forming a subdivision of an order, as the congregation of the Oratory, or of Cluny among the Benedictines. The congregation of the Lord' was an appellation assumed by the Scotch Presbyterian Reformers, who called the church of England the congregation of Satan. They appeared first in 1557, under the earl of Argyle, and were subsequently led by John Knox.

Congregationalists are those who compose the congregations which assume an independence not only of the ecclesiastical control of the established hierarchy, but of all authority extraneous to the constituency of the congregation itself. They may therefore in general be said to be identical with the Independents. They are said by some to have appeared first in 1616, under the conduct of Mr. Jacob. (Evans's '*View*.') But they are generally considered to be of the same origin as the Brownists, who appeared in 1600. [BROWNISTS.] The real founding of the sect is attributed to Mr. Robinson, in 1640, and the following passage from his 'Apology,' c. 5., p. 22, is adduced as their leading maxim. 'Cœtum quemlibet particularem esse totam, integram et perfectam ecclesiam, ex suis partibus constantem immediatè et independenter sub ipso Christo.' It is said that they adopted the name of congregational brethren, and congregational churches, to avoid the odium of sedition and anarchy which was charged upon them as the Puritan regicides of Charles I. Cromwell made use of them as a political check on the Presbyterian party. (See 'Declaration of the Faith and Order owned and practised by the Congregational Churches in England,' 1658.) In the six New England States of North America, which were colonized by the English Puritans, the Congregationalists are very numerous; and in several other parts of the union their numbers are much larger than those of other sects. Their creed and the rules of their democratic government are given fully in their 'Platforms of Discipline.' They believe in 'The Trinity; Predestination; Total Depravity; Particular Redemption; Effectual Grace and Final Perseverance;' and maintain that 'Every congregation of visible saints, furnished with a pastor, is under no other ecclesiastical jurisdiction whatever.' (Mosheim, vol. v., p. 398; Neal's *Hist. Puritans*, vol. ii., p. 107; vol. iii., p. 547; vol. iv., p. 187; Burnet's *Hist. Own Times*, vol. i., p. 16; Adam's *Dict. of Religion; Reasons against the Indepen. Gov. of Congregations.*)

CONGRESS, AMERICAN. [UNITED STATES OF N. AMERICA.]

CONGREVE, WILLIAM, was the second son of Richard Congreve of Congreve in Staffordshire, and born at Bardsa, near Leeds, in Yorkshire. His father, who held a commission in the army, took him over to Ireland at an early age, and placed him first at the Great School at Kilkenny, and afterwards under the direction of Dr. St. George Ashe, in the University of Dublin. After the revolution in 1688 he returned to England, and was entered as a student in the Temple. His first play, written at the age of nineteen, was the 'Old Bachelor,' which was produced with great applause at Drury-Lane in 1693; and Dryden is said to have remarked that he had never seen such a first play. The next year he produced 'The Double-Dealer,' and in 1695, joining with Betterton, they commenced their campaign at the new house in Lincoln's Inn Fields with a new comedy written by Congreve, called 'Love for Love.' In 1697 he produced his tragedy of 'The Mourning Bride,' and two years afterwards the comedy of 'The Way of the World.' The indifferent success of this last play disgusted him with the theatre, and he determined to write no more for the stage. Through the friendship of his patron the Earl of Halifax, he was first made one of the commissioners for licensing hackney-coaches, then presented with a place in the Pipe Office, and after that with one in the Customs, worth 600*l.* per annum. On the 14th of November, 1714, he was appointed commissioner of wine licences, and on the 17th of December, in the same year, nominated secretary of Jamaica. The last twenty years of his life were spent in retirement, and towards its close he was much afflicted with the gout and with blindness. Being overturned in his chariot on a journey to Bath, he received, it is supposed, some internal injury, and, gradually declining in health, died on the 19th of January, 1729, at his house in Surrey Street in the Strand, London, aged 57, and was buried on the 26th of January, in Westminster Abbey. Mr. Congreve was also the author of a romance called 'The Incognita, or Love and Duty reconciled,' written at the age of seventeen; 'The Judgment of Paris,' a masque; 'Semele,' an opera, and several poems. His merit as an *original* writer Johnson pronounces to be of the highest kind, as he 'borrowed neither the models of plot, nor the manner of his dialogue.' Of his plays, he remarks, that his characters are commonly fictitious and artificial, with very little of nature, and not much of life. His scenes exhibit not much of humour or passion; his personages are a kind of intellectual gladiators—every sentence is to ward or strike; the contest of smartness is never intermitted; his wit is a meteor, playing to and fro with alternate coruscations. 'His comedies, therefore,' observes the critic, 'have in some degree the operation of tragedies—they surprise rather than divert, and raise admiration oftener than merriment.' His only tragedy, 'The Mourning Bride,' although very successful, is a piece of unrelieved bombast. 'Love for Love' is the only play of Congreve's which has still possession of the stage, and even that is rarely acted, as its wit cannot atone for the exceeding grossness of much of the dialogue.

CO'NI, or more generally **CU'NEO**, a province and town of the Sardinian states in the south-west part of Piedmont, near the foot of the Maritime Alps, which divide it from the county of Nice and from France. The province of Cuneo is bounded on the north by the province of Saluzzo, east by that of Mondovi, south by that of Nizza, and west by the French department of Basses Alpes. It is a country of valleys, which slope down towards the great valley of the Po, and in which the Grana and the Macra, affluents of the Upper Po, the Stura and its affluents, and several of the affluents of the Tanaro have their source. The valleys, which are naturally fertile, are improved by the excellent system of irrigation. The principal products are corn, wine, hemp, hay, and silk. The south and west borders of the province lie among the Alps, the lower slopes of which are covered with chestnut trees, and the upper parts afford summer pasture. The length of the province west to east from the sources of the Stura to the borders of the province of Mondovi near Chiusa, is about forty miles, and its greatest breadth from north to south from Fossano to the Col di Tenda, is about thirty miles. The population is reckoned at 143,000. (Serristori, *Saggio Statistico.*) The province contains several considerable towns: 1. Cuneo, the capital, and a bishop's see, has a royal college, and 18,000 inhabitants, and is the residence of the intendente and of the military governor. It was formerly a place of great strength, and sustained several sieges; but its fortifications were razed in 1801. A navigable canal runs from Cuneo to Carmagnola, uniting the Stura with the Po. The high road from Nizza to Turin by the Col di Tenda passes through Cuneo. 2. Fossano, with 12,500 inhabitants, and a bishop's see, situated in a fine plain near the Stura, has a royal college, and a college for boarders, kept by the Fathers Somaschi. 3. Demonte, in the valley of the Upper Stura, on the road leading to the Col de l'Argentiere, has 6400 inhabitants, and a grammar-school kept by the Scolopj. The mineral baths of Vinadio, a few miles above Demonte, have considerable reputation. 4. Dronero, in the valley of the Macra, has 6700 inhabitants, and a college. 5. Caraglio, 5800 inhabitants, and a college. 6. Busca, on the road from Cuneo to Saluzzo, 8000 inhabitants, and a college likewise. 7. Boves, 7700 inhabitants, and a grammar-school. 8. Chiusa, 5500 inhabitants, and a grammar-school. 9. Centallo, on the road from Cuneo to Turin by Savigliano, has 4400 inhabitants. 10. Limone, at the foot of the Col di Tenda, has 3400 inhabitants, many of whom are employed with their mules in carrying goods and passengers over the mountain. There are besides in the province of Cuneo several other small towns, of between 2000 and 3000 inhabitants. (*Calendario Generale dei Regj Stati*, Torino, 1824.) These valleys were in antient times inhabited by the Vagienni, a tribe of the Ligures. The Roman colony of Pedona is believed to have stood where Borgo San Dalmazzo now is, a few miles south of Cuneo. Augusta Vagiennorum stood farther north, near Fossano. All traces of those colonies became lost in the middle ages, and it is believed that they were destroyed by the Saracens, who from their stronghold of Frassineto near Nizza infested and devastated these valleys in the tenth century of our æra. (Jacopo Durandi, *Delle Antiche Città di Pedona, Caburro, Germanicia, ed Augusta de' Vagienni.*)

CONIA. [CIRRHIPEDA.]

CONIC SECTIONS, the curves formed by the intersection of a circular cone and a plane, the former being either oblique or right.

Though the name of conic sections still remains, yet the interest which attaches to these curves, and the method of treating them, has no longer any reference to the accident from which they derive their name. The Greek geometers, in pure speculation, occupied themselves with the different methods in which a cone may be cut, simply because the conical surface (with the cylindrical and spherical) came within the restrictive definitions under which they had placed geometry. [GEOMETRY.] The works of APOLLONIUS and ARCHIMEDES are the first in which these sections were treated; and their history is nothing but that of the addition of a few remarkable properties, till the discovery that the path of a projected body in an unresisting space is a parabola, and that of a planet round the sun, an ellipse. [GALILEO, KEPLER.] Since that time we might as well attempt to write the history of mathematics and physics as that of conic sections in their results and consequences: and from that time we have nothing to say of them merely as *conic sections*.

Some sections of a cone are considered in elementary geometry, for a plane may meet a cone in a point, or in a single straight line, or in two intersecting straight lines, or in a circle. But the curves which are peculiarly conic sections, are the oval made by a plane which cuts the cone entirely on one side of the vertex, called the ELLIPSE: the indefinitely extended modification of this when the plane becomes parallel to any one slant side of the cone, called the PARABOLA: and the curve which is partly on one side, and partly on the other of the vertex, formed by a plane which cuts both surfaces of the cone, called the HYPERBOLA. To these names we refer for the specific properties of the sections.

Algebraically considered, the *conic sections* are the *curves of the second degree*, meaning the curves belonging to such equations between co-ordinates are of the second degree. Thus x and y being co-ordinates, oblique or rectangular, the general equation

$$ax^2 + bxy + cx^2 + dy + ex + f = 0,$$

may, by properly assuming a, b, c, &c. be made the equation of every possible section of a cone by the plane in which the co-ordinates are measured. As very many elementary works do not fully discuss the conditions under which the preceding equation represents the different sections, we subjoin the following from the 'Camb. Phil. Trans.', vol. v. p. 89. In the following list θ means the angle made by the co-ordinates. [The notation has reference to the table in SURFACES OF THE SECOND DEGREE.]

$$\text{Let } V_1 = a + c - b\cos\theta \qquad V_2 = 4ac - b^2;$$

$$W' = \frac{cd^2 + ae^2 - bde}{b^2 - 4ac} + f,$$

and in the case where V_2 and $cd^2 + ae^2 - bde$, are both $= 0$, let

$$W'' = \frac{4af - d^2}{4a} = \frac{4cf - e^2}{4c}.$$

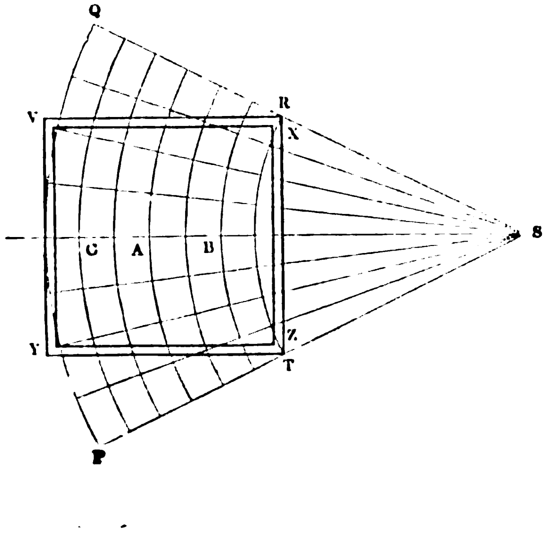
In the following table, p means either sign, + or −, but in the same line, n means the other sign; a dotted line means that the sign of the expression at the head of the column need not be considered. The word line by itself means straight line.

W'	V_2	W''	V_1	Name of the Section.
p	+		p	Impossible.
p	+		n	Ellipse.
....	−		....	Hyperbola.
0	0		....	Parabola.
0	+		....	Point.
0	−		....	Intersecting lines.
$0 \div 0$	0	p	p	Impossible.
$0 \div 0$	0	p	n	Parallel lines.
$0 \div 0$	0	0	....	Line.
$0 \div 0$	0	α	....	Line.

Thus if W' and V_1 both have the same sign, and V_2 be positive, the equation cannot be satisfied at all; but if W' and V_1 be of different signs, and if V_2 be positive, the equation is that of an ellipse. We may add that $V_1 = 0$, indicates an equilateral hyperbola. [HYPERBOLA.]

The general properties of the sections are numerous and interesting, but we shall only mention one, because it is the most convenient as a general definition of the curves, combining them at once with each other, in a manner to which algebra is easily applied. If a point move in such a way that its distance from a given point (called the *focus*) always is the same fraction of its perpendicular distance from a given right line (called the *directrix*), then the curve traced out is an ellipse, parabola, or hyperbola, according as the given fraction is less than, equal to, or greater than, unity. We are convinced that no method of deducing the properties of these curves can be very successfully applied in the case of beginners, unless it involve the foci in the definition. The properties of these points do not readily show themselves either in the deduction from the cone, or from the general algebraic equation.

CONICAL PROJECTION. A method of describing a representation of a part of sphere upon a plane. A sphere cannot be unrolled into a plane, as can every cone or portion of a cone. If a cone be described which touches a sphere in a small circle, and if the several points of the sphere be then projected upon the cone by lines drawn through the centre, the parts adjacent to the small circle of contact will be projected into figures very nearly similar to the originals. If the degrees of latitude, which are very nearly equal, be made actually equal, no injurious effect will be produced on the map. Suppose, for instance, it is required to draw the map of a country contained between two given longitude circles, and two given parallels of latitude.



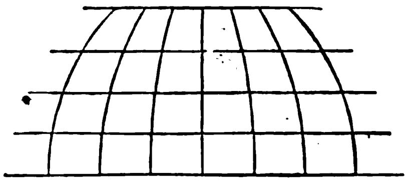
Take any radius for the sphere, and let S A be the radius × cotangent of the middle latitude of the map. From A set off A B, A C, &c., equal to the arc of one degree (or whatever the distance may be between the parallels which it is desired to draw) on the great circle of the sphere chosen. Let L° be half the total longitude contained between the extremities of the map, and take the angles A S P and A S O, equal to L° × the sine of the middle latitude. Divide the angle Q S P into as many parts as there are degrees (or other required intervals of longitude lines) in L: then Q R T P is the map required, and V X Y Z such a portion as is usually exhibited on a sheet of paper.

If instead of the tangent cone, it be required to project upon the cone formed by the revolution of the chord which joins the two extreme points of the map on the sphere, let l and l' be the least and greatest latitudes, and let

$$SR = \text{radius} \times \cos l' \div \sin \tfrac{1}{2}(l + l')$$
$$SQ = \text{radius} \times \cos l \div \sin \tfrac{1}{2}(l + l')$$

the rest is as before.

There are two modifications of this principle which it will be convenient here to notice; the projection used by Flamsteed, and that adopted by the French government in their recent maps. In Flamsteed's projection the degrees of latitude are equal, and the parallels of latitude are perpendicular to the middle longitude circle, which is a vertical right line. But the degrees of longitude are made in every parallel to bear the same proportion to the degree of latitude as on the globe: so that the meridians are, in fact, curves, the ordinates of which are as the cosines of the abscissæ.



In the French government maps, the same plan is adopted, with this exception, that the parallels of latitude are the circles of the conical projection, and the degrees of latitude are all equal (the oblateness of the earth may be allowed for, if thought necessary); the degrees of longitude are then set off on the parallels of latitude in the same proportion as in Flamsteed's projection.

CONI'FERÆ, a natural order of Gymnospermous exogens, consisting of resinous, mostly evergreen, hard leaved trees or shrubs, inhabiting all those parts of the world in which arborescent plants can exist. Under this name are collected the various races of fir trees, pines, cedars, junipers, cypresses, and the like, which, however dissimilar they may at first sight appear, correspond not only in their universally terebintaceous sap, but in the following points of organization:—They all branch from numerous buds, proceeding from the side of a main stem. Their wood consists of tubes of nearly equal diameter, among which are here and there fistular cavities which receive the resin that exudes from the wood. The sides of the woody tubes are marked by circular disks, which, when highly magnified, appear as if consisting of a smaller internal and a large external circle; the nature and use of these disks is unknown. The following cut represents highly-magnified sections of a piece of deal; A shows the nearly equal size of the woody tubes when viewed transversely. B is a perpendicular section with the disks seen on the sides of the tubes.

The leaves are articulated with the stem, and very often are linear, veinless, and sharp-pointed; but in some cases, as Salisburia adiantifolia, *fig.* 1, and Podocarpus asplenii-folia, *fig.* 2, the leaves become broad, and then they are filled with veins, which are all of the same size, and branch by repeatedly forking; a mode of veining known only in

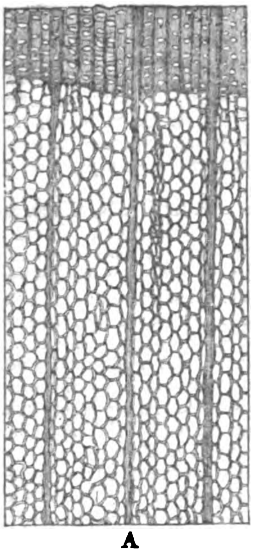


Fig. 1.

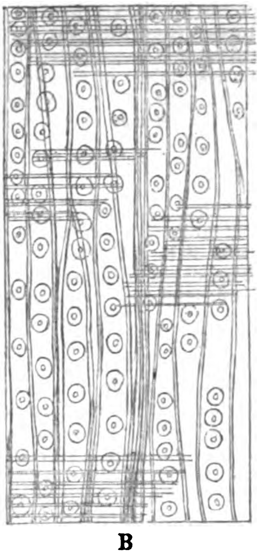

Fig. 2.

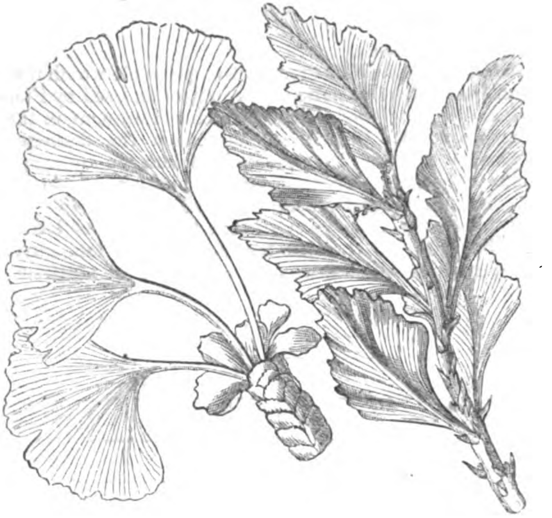


[Salisburia adiantifolia.] [Podocarpus aspleniifolia.]

these plants and in ferns. The flowers are collected in little scaly cones; males in one cone, and females in another. The females have no pericarpial covering, but consist of naked ovules, to which fertilization is communicated directly from the pollen, without the interposition of a style or stigma. When the fruit is ripe it consists of a certain number of scales collected into a cone, and inclosing the naked seeds in their axils. Sometimes such scales are thin as in the larch, or hard and long as in the pine, or even succulent as in the juniper, whose berries, as they are named, are small cones with succulent consolidated scales.

Coniferæ are among the most useful of all plants, firstly, for their resinous secretions, such as pitch, turpentines of different kinds, Canada balsam, and similar substances; secondly, for their timber, which under the names of deal, fir, pine, red cedar, Sandarach wood, &c., is most extensively used in building; and thirdly, because of the screen which their compact, evergreen leaves oppose against cold, in barren, bleak situations, where few other trees will grow. [ABIES, PINUS, CUPRESSUS, THUJA, JUNIPERUS, ARAUCARIA, &c.]

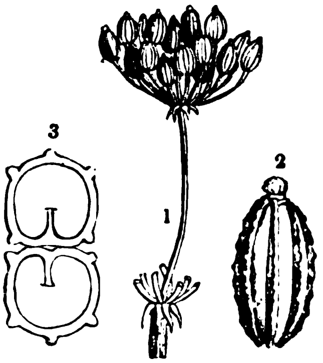
CONILIRA. [ISOPODA.]

CONILITES. [ORTHOCERATA.]

CONIPORA. [POLYPIARIA MEMBRANACEA.]

CONIROSTRES (Zoology), the third family of Cuvier's Passeres, comprising those genera which have a strong bill, more or less conical, and without notches. Cuvier says that they live more or less exclusively upon seeds, in proportion as their bill is more or less thick. The *Conirostres* form one of the five tribes of the order *Insessores* of Mr. Vigors. [BIRDS, vol. iv., p. 431.]

CONI'UM MACULA'TUM, or HEMLOCK, is a wild umbelliferous plant, possessing highly narcotic and dangerous qualities, but used medicinally as a remedy against nervous affections It has a white fusiform biennial root; an erect, branched, bright green, spotted stem, from five to ten feet high, on which are planted so many smooth, finely cut, large, fern-like leaves. When very healthy and growing in a spot where it is neither injured by storms nor disfigured by dust, the hemlock is one of the most noble of all wild plants. Its little greenish white flowers, arranged in umbels after the manner of its order, have a minute involucre of several leaves at the base; and the partial umbels have also three or four short oval leaflets on one side. The fruit is globular, each half having five projecting angles which are slightly crenelled, without either vittæ or appendages or projections between them. It grows in wild places, sometimes by the sides of ditches in meadows, but more frequently in light upland pastures, flowering in June and July. It is almost the only wild umbelliferous plant whose fruit is destitute of vittæ, and consequently not aromatic.



[Fruit of Conium maculatum.]

1. A partial umbel loaded with fruit, natural size. 2. The back view of a fruit, much magnified. 3. A transverse section of the same, showing the ridges, the absence of vittæ, and the involute albumen.

It is necessary to pay the greatest attention to the botanical characters of Conium maculatum, in order that the genuine one may be collected. Sometimes plants resembling it are collected, which are almost or entirely inert when employed as a medicine, or plants possessed of greater potency are used in its stead, from which fatal results have followed. It is a 'well-known cirumstance that the greatest discrepancy prevails among medical men as to the activity of hemlock, not merely as a remedy but also as a poison.' This discrepancy admits of satisfactory explanation on several grounds. The activity of the plant—even supposing the proper one to be collected—depends greatly upon its place of growth, the kind of season, the time when collected, and the means employed to dry it or form it into an extract, on the temperature and dryness of the place where it is preserved, and on the length of time it has been kept. In the south of Europe it is much more energetic than in the north, owing to the greater intensity of light: even in the southern provinces of France it is more powerful than in the northern. The wild plant, growing in well-exposed situations, is always to be preferred to a cultivated one; the kind of season markedly influences its power, which is greatest in a dry sunny season, and least in a wet gloomy one. The leaves during the first year of growth possess little potency; nor do they possess much during the early period of the second, till the flower-stem is developed, and the flowers are about to expand. If this period, which is the fittest time for collecting the leaves, is allowed to pass, it is better to wait two months longer and collect the fruits instead, as they become the recipient of the active principle. The leaves should be dried quickly, but not by the application of a high temperature; they should never be powdered till the time when it is intended to use them, but preserved meanwhile in a cool dry place. If an extract be formed which requires much care in the preparation, it can rarely be kept beyond twelve months. A fresh supply of leaves, fruits, or extract, should consequently be procured every year, and the former thrown away, as the action of time or heat volatilizes the active principle (Conia), and renders the residue nearly inert. When these precautions are attended to, hemlock is a medicine of great power, and unquestionable value.

The fresh leaves are dark green, shining; odour strong, stupifying, unpleasant, resembling that of mice, or the urinous odour of fresh Spanish flies; when dried the colour is lighter, a greyish green; the taste is disagreeably saline, nauseously bitter, and at last somewhat acrid. The expressed juice is green.

The active principle of hemlock appears to be an alkaloid termed *conia*, which, unlike most vegetable alkaloids previously known, is not fixed and crystalline, but volatile and oleaginous. It has been obtained both from the leaves, and fully developed but still green fruits. Its activity is increased by union with acids, both mineral and vegetable; a circumstance which shows the impropriety of giving vinegar as an antidote in cases of poisoning by hemlock, when any of the substances is yet present in the stomach. Conia is sparingly soluble in water, to which it imparts its odour and taste. It also combines with about a fourth of its weight of water to form a hydrate of conia. When exposed to the air it quickly contracts a dark brown colour, and is slowly resolved into a resinous matter, with the disengagement of ammonia. This change takes place more promptly under the co-operation of heat; but even at common temperatures it is so apt to ensue, that unless the alkaloid be kept very carefully excluded from the air, discolouration will take place in a few hours. Though conia exists in the plant in combination with some acid, which may render it less alterable, yet its proneness to decomposition is so great, that either by time or the application of a considerable degree of heat, it may be entirely dissipated; which accounts for the inertness of old leaves, and of most extracts which have not been prepared with the greatest care. Geiger says that the dried leaves do not contain conia; a statement which, if correct, leads to the conclusion that conia, though the most powerful, is not the only efficient agent in hemlock.

Conia appears, from the experiments of Geiger and Christison, to be a deadly poison to all animals. It acts with the most extraordinary rapidity; but if it fail to kill, its injurious action passes quickly away, and perfect recovery follows. It acts through every texture of the body where absorption is readily carried on. It acts as a local irritant; but its ultimate and fatal energy is chiefly exerted on the spinal chord, to which its influence is conveyed by entering the blood and producing on the inner membrane of the blood-vessels a peculiar nervous impression, which is instantly conveyed by sympathy along the nerves to the organ remotely and ultimately affected. 'It exhausts the nervous energy of the spinal chord, producing general muscular paralysis and asphyxia from relaxation.' The heart however is exempt from this general paralysis, contracting vigorously for a long time after all motion and respiration and other signs of life are extinct. It is therefore extremely probable, as suggested by Dr. Christison, that where a dose is not so large as to produce immediate death, the carrying on of artificial respiration and administering vital stimulants, might save the life of the patient, especially as the action of the poison is so transient, and incapable of producing a permanently injurious impression.

In what way hemlock proves useful as a remedial agent in many diseases is by no means clear, unless it be by allaying irritability in the diseased parts, and giving an opportunity to the vital powers to recover their healthful action. That it lessens irritability in many diseased organs is certain, from the effects of the administration of even a few doses, especially in many cases of scrophulous affections, and above all from allaying the irritation of the lungs during the formation of tubercles, and indeed during all the subsequent stages of consumption. Even when inhaled along with the vapour of warm water the same good effect is said to follow, but this is rather doubtful. Its beneficial influence over external ulcers is however open to observation; and John Hunter remarked, that under the combined action of conium and cinchona-bark, many obstinate buboes, which resisted every other mode of treatment, soon took on a healing process. Many irritable or painful ulcers are soothed and improved by a hemlock poultice. Rheumatic pains, and those attending nodes, are most effectually allayed by conium and ipecacuan. From the very decided sedative action of conia on the spinal chord, Dr. Gordon has suggested that it will prove a useful remedy in tetanus, and other spasmodic diseases. The catalogue of diseases in which it has been found useful might be greatly extended, but enough has been advanced to prove its value, and consequently the propriety and necessity of attending to the above-mentioned rules to obtain it in an efficient state. When the fresh leaves cannot be obtained, owing to the season of the year, the extract may be used. Dr. Christison states, that from an alcoholic extract he obtained the greatest quantity of conia: he was therefore disposed to consider this the most powerful form of preparation. But a carefully prepared watery extract which has subsequently been submitted to trial by him, was found to be, in equal doses, as powerful as the alcoholic.

Dr. Christison is of opinion that the Conium maculatum of the present day is not the plant which furnished the poison employed to dispatch Phocion and Socrates.

For many important particulars in this article we are indebted to Dr. Christison's 'Memoir on the Poisonous Properties of Hemlock and its Alcaloid, Conia.' (*Trans. of Royal Society of Edin.*, vol. xiii.)

CONJEVERAM, so called from a highly venerated pagoda built there, and dedicated to Vishnu Conjee, is a populous and flourishing town, in the district of Chingleput, in the Carnatic, in 12° 49′ N. lat., and 79° 41′ E. long. The town, which stands in a valley, is built in a straggling manner, being more than five miles long: the houses, many of which are handsome, are separated by extensive gardens and plantations of cocoa-nut trees. The town is surrounded by a hedge of the Agave Americana, a plant formerly much used in India as a defence against the incursions of bands of horsemen, who were accustomed to commit depredations upon defenceless places. The valley in which the town is placed is watered by the small river Wegawutty. Besides the pagoda above mentioned, there is a very large and lofty temple, dedicated to Siva, the view from which is very magnificent. Considerable manufactures of cotton goods, chiefly red handkerchiefs and turbans, are carried on in the town, where the weavers set up their looms under the shade of the trees. Conjeveram is celebrated in the antient history of the country, and is well known to Europeans as having been the frequent seat of military operations during the Carnatic wars: the town is forty-eight miles S.W. from Madras. (Heyne's *Historical and Statistical Tracts on India.*)

CONJUGATE. This word is used in several branches of mathematics in a sense which (with one exception, and that might easily be abolished) may be described as follows: two points, lines, &c., are called conjugate, when they are considered together in any property in such a manner that they may be interchanged without altering the way of enuntiating the property. Thus if A C be to C B as A D to D B, C and D are conjugate points with regard to this property.

If we write D where C now is, and C for D, the property is still expressed in exactly the same way. We have other instances in conjugate diameters, conjugate hyperbolas [ELLIPSE, HYPERBOLA], conjugate foci. [LENS, MIRROR.]

The instance of exeption is the conjugate point of a curve, meaning a single point lying by itself, whose co-ordinates satisfy the equation of the curve, without its actually being on any continuous branch of the curve. [CURVES, THEORY OF.] It would be better to call this point *conjunct* than use a term which destroys the generality of language. But the best term, in our opinion, would be *evanescent oval*. [See the article already cited.]

CONJUGATION of a verb is a term in Grammar denoting the addition of suffixes or prefixes to the crude, or elementary form of a verb, for the purpose of denoting respectively, person, number, time, state, mood, and what is generally understood by voice. In the English language, prefixes are commonly used for these purposes, and these prefixes are not printed in connexion with the verb, though the voice presents them in one mass. Thus *I shall have heard*, as pronounced, is not less one word than the Latin *audi-v-er-o*. In this example therefore, *I*, *shall*, *have*, are virtually prefixes, and the letter *d*, a contraction from *ed*, is a suffix attached to the simple verb or crude form *hear*. In the ancient languages, such as Greek, Latin, and Sanscrit, suffixes are commonly but not exclusively preferred.

The suffixes which denote the *persons* are the personal pronouns more or less corrupted. Thus in Latin, *egomet* is the full form of the pronoun which signifies *I:* but as three syllables would be too long for a term in such frequent use, and this inconvenience in the present instance would be aggravated by an appearance of egotism, the word was shorn of its exterior letters, and at the utmost the three middle letters, *ome*, were attached to the verb. We see them in the Greek form *tupt-ome-s* or *tupt-ome-n*, 'we strike.' In the Latin, the vowels were corrupted, so that instead of *ome*, either *umu* or *imu* occur, as in *s-umu-s*, 'we are;' *poss-umu-s*, 'we are able;' *scrib-imu-s*, 'we write.' The old German has nearly the same suffix in *war-ume-s*, 'we were;' *bir-ume-s*, 'we be.' Again the three letters, *ome*, deprived of the last vowel, became *om*, as Greek *tupt-om-ai*, 'I strike myself;' *um*, as Latin, *s-um*, 'I am;' *poss-um*, 'I am able;' or *on*, as Greek, *e-tupt-on*, 'I was striking.' But the first vowel might disappear instead of the last. Thus *me* is the form which appears in the Greek *es-me-n*, or *es-me-s*, 'we are;' *mi* is used in *es-mi*, *e-mi*, *ei-mi*, 'I am;' *di-do-mi*, 'I give,' &c. Sometimes the *m* is all that appears, as *scribeba-m*, 'I was writing.' In Greek, this final *m*, by a principle constantly observed in that language, becomes an *n*, as *e-n*, 'I was;' *etetuphei-n*, 'I had struck.' Another form of the suffix is *o*, instead of *om*, which is common both in the Greek and Latin, as Greek, *tupt-o*, 'I strike;' Latin, *scrib-o*, 'I write.' Finally, all trace of the pronoun at times disappears, and the defect ceases to mislead because the other persons have their characteristic terminations. Thus the Greek tenses, *etupsa*, 'I struck;' *tetupha*, 'I have struck;' and *etetuphea*, 'I had struck,' contain no remnant of the pronoun. In the English language there are some slight traces of the personal suffixes, which existed in full perfection in some of the older forms of the Teutonic languages. The word *am* has a remnant of the first person suffix in its final *m*.

The second person in the Greek and Latin languages, was *su* or *tu*, in German, *du*, and in English, 'thou.' Accordingly we find a sibilant attached to the verb to denote the second person, as in the Greek, *es-si*, 'thou art;' *ois-tha*, 'thou knowest;' *tupt-es-ai*, 'thou strikest thyself;' in the Latin, *scrib-is*, 'thou writest,' and in the English termination *est* in *knowest*, *strikest*. But as the Latin form has a *t* instead of an *s*, *tu* not *su*, so the *t* occasionally appears as in Greek, *tupt-ete*, 'you strike;' Latin, *scribiti-s*, 'you write;' and in the English, '*art*,' 'thou art.'

The third person is an indefinite term; and the suffix which denotes it is derived from *to*, signifying *this*, which is the full form of the Greek article, and again appears, on the one hand in Latin, in the derivatives, *tam*, *talis*, *tantus*, *tot*, *tum*, and on the other in the English, *the*, *this*, *to-day*. It is therefore as general as the English article *the*, and may denote indifferently, the *man*, *the woman*, *the thing*, in other words, *he*, *she*, *it*. It appears as a suffix in the Greek, *es-ti*, 'he is' (Sanscrit, *as-ti*); *tupt-et-ai*, 'he strikes himself;' in the Latin, *es-t*, 'he is,' *scrib-it*, 'he writes;' and in the obsolete form of the English language, *walk-eth*, now corrupted into '*walks*.'

Suffix of *number*. If a sign be employed to denote plurality, the absence of that sign will be a sufficient indication of the singular. Now the suffixes of plurality in English are *s* and *en*, as in *dogs*, *oxen*. The same are employed in Greek and Latin, as, first person, Gr., *tupt-ome-s* or *tupt-ome-n*, Lat., *scrib-imu-s;* second person, Lat., *scribiti-s*. The Greek has dropped the *s*, as in *tuptete*, a corruption probably of *tupteti-s*, just as the Latin imperative *scribite*, must be looked upon as reduced from *scribitis*. In the third person the mark of plurality appears to have been prefixed to the pronoun suffix, as in the Greek, *pha-n-ti*, 'they say;' *tupt-on-ti*, 'they strike;' Lat., *scrib-un-t*, 'they write.'

Time or tense (Fr. *temps*) divides itself into past, present, and future, where again the idea of present time will not require any peculiar distinction, if the ideas of past and future have their proper symbols. The past time appears to have had for its characteristic, either the prefix, *e*, or the suffix, *sa*, *ha*, or *a*. The former appears in the Greek, *e-tupt-on*, 'I was striking;' *e-tup-sa*, 'I struck;' *e-tetuphea*, 'I had struck.' The second appears in two of the Greek forms just enumerated, and in the Latin, *scribeb-a-m*, 'I was writing;' *er-a-m*, 'I was.' A very distinct example of a future suffix appears in those European languages which are derived from the Latin. Thus in the French, *écrir-ai*, we have really two distinct words, the infinitive, *écrire*, and *ai*, the present tense of *avoir*, forming altogether, *écrir-ai*, 'I have to write,' *i. e.*, 'I shall write.' This origin of the French future is placed beyond a doubt by a comparison with the Spanish and Italian.

By the term *state*, which stands fourth in the series of suffixes which have been included in the definition of conjugation, it was intended to denote the notions of perfect and imperfect action. Here again one suffix is sufficient, and the notion of completeness is variously marked:—1st. By a doubling of the verb upon itself. The purest example of this is presented in the Gothic, as *laia*, 'I laugh;' *lailō*, 'I laughed;' *stauta*, 'I strike;' *staistaut*, 'I struck.' The Greek have perfects formed upon this principle in *te-tupha*, *ge-grapha;* the Latin in *te-tul-i*, *de-d-i*, *spo-pond-i*, (for the less easily pronounced *spo-spond-i*.) And in our own language there is strong reason for believing that such is the origin of *did*, the perfect of *do*. Out of the same principle grows the formation of the perfect by a long vowel, *vēni* being probably a contraction from *vĕ-vĕn-i*. 2nd. By affixing the letter *s*, which is probably a corruption of the verb *es*, to be; a supposition strengthened by the fact, that the past perfect *scrips-eram*, and the future perfect *scrips-ero*, are undoubtedly formed by the addition of *eram* and *ero* from that verb. The same would also be found on investigation to be the case in the Greek *etetuph-ea*, 'I had struck;' and lastly, in our own language the same verb is used for this purpose in such phrases as '*I am recovered*.' 3rd. By the letter *v*, which may possibly be a remnant of the auxiliary verb *habe*, 'have,' in accordance with the practice of nearly all the languages of modern Europe. Examples of this suffix are abundant in Latin, as *ama-vi*, 'I loved.'

The suffixes of the *moods* could not be placed in a distinct point of view without a detailed investigation. It may be sufficient to point out that *to* is distinctly observable as a suffix in those parts of the so-called Latin imperative, which strictly deserve that title; for the forms which do not contain the syllable in question, are at the same time devoid of the notion to command. That the suffixes of the potential, subjunctive, and optative moods, in the Greek and Latin, were originally distinct words, and perhaps verbs, like our own *may*, *can*, &c., is probable from general principles, and is confirmed by the appearance of the separate particles *ken*, *ke*, *an*, in the Greek language, which are used in connexion both with the indicative and other moods.

The last suffix for consideration is that which denotes the *voice*. The Greek grammarians acknowledge a middle or reflective voice; but the Latin language in fact possesses the same, as for instance in *accingo-r*, 'I gird myself for the contest;' *nito-r*, 'I support myself;' *lavo-r*, 'I wash myself,' 'I bathe.' And in both languages the middle voice is the parent of the passive. This may be illustrated by such phrases as the French *les bas se vendent ici*, 'stockings sell themselves here,' *i. e.*, 'are sold;' the Italian *si dice*, 'it is said,' strictly *it says itself*. Now the suffix of the Latin passive appears in the various forms *ur*, as *monet-ur*, *er* as *moneri-er*, *r* as *moneo-r;* but the attentive Latin student is ever ready to suspect when he meets with an *r*, that an older form of the word contained an *s;* and in fact we find an *s* in the form *moner-is*, where moreover the first part *moner* is another example of the corruption in question, for it supplies the place of *mones*. If then *s* is the original consonant of this suffix, we are forthwith directed to the reflective pronoun *se;* nor ought we to be stopped by the fact that this pronoun in Latin is confined to the third person. In the Russian and other Sclavonic languages, the connexion of which with the Teutonic languages and with those of Greece and Rome is indisputable, the reflective pronoun, containing in fact the very same root as *se*, is applicable alike to all the persons; and indeed there was nothing in the nature of things to limit the Latin pronoun as to *person*, when it is confessedly unlimited as to *gender* and *number*.

The division of verbs into several conjugations depends upon the last vowel or consonant of the verb in its simple or crude state. Thus in the Latin language all verbs ending in *a* are said to be of the first conjugation, all that end in *e* of the second, those in a *consonant* or *u* of the third, and those in *i* of the fourth or last; for it accidentally happens that the Latin language possesses no verbs in *o*, except the fragmentary forms *gnovi*, *gnotus*, *potus*, *ægrotus*, which appear to imply the existence of stems in *o*, viz., *gno* (in English, 'know'), *po* (compare the Greek *pe-po-ka*), *ægro*. The Greek language is not without a class of verbs having *o* for the final letter, as *doulo*, enslave, &c. The division of verbs into conjugations is founded upon the fact that the union of the final letters in the crude form of the verb with the initial letters in the suffixes leads to changes dependent upon these letters.

CONJUNCTION and OPPOSITION (Astronomy). Two heavenly bodies are said to be in conjunction with respect to a third, when they have either the same longitude (measured on the ecliptic of the third) or the same right ascension (measured on its equator). But as it is the second position which is usually meant by conjunction, the first is called the ecliptic conjunction. Thus in every eclipse of the sun, there is a conjunction of the sun and moon, both equatorial and ecliptic, not however at the same moment, unless the eclipse be perfectly central. There is also a conjunction at every new moon.

Opposition (equatorial or ecliptic) is when the bodies are exactly of opposite right ascensions or opposite longitudes, that is, when their longitudes or right ascensions differ by 180°. Thus there is always an opposition of sun and moon at every full moon, and both oppositions are at the same moment in the middle of a central eclipse.

The conjunction of a planet with the sun prevents its being observed, as it is then always in the brightest part of the heavens: it is nevertheless an important element in the theory of the planets. But at the opposition (an equally important point in theory) the planet is always in the darkest part of the heavens. Both therefore in theory and practice, comparisons of observations and theory near the opposition are desirable: and accordingly astronomical ephemerides usually give very close computations for these periods.

Apparent conjunction and opposition take place when the right ascensions are the same, or opposite to the spectator or the earth's surface: *true* conjunction, &c., refers to a spectator supposed to be at the earth's centre. [APPARENT.]

CONJUNCTIONS. Under this term grammarians commonly include several classes of words which have little similarity of meaning, and which, in their etymological origin, may be verbs, substantives, adjectives, or prepositions. The old definition of a conjunction, that it was a word which connected sentences together, will certainly not apply in all cases, if at least the word 'and' is to be included. It is true, as Horne Tooke observes, that "the sentence 'You and I and Peter rode to London' may be resolved into three: 'you rode,' 'I rode,' 'Peter rode.' But try some other instances: 'two and two are four;' 'AB, BC, and CA form a triangle;' 'John and Jane are a handsome couple.'—Does AB form a triangle?—Is John a couple?—Are two four?" (*Diversions of Purley*, Taylor's edition, i., p. 210.)

On the etymological origin of conjunctions, which is a distinct question from their use, some remarks will presently be made; in reference to their employment in the construction of a simple or compound sentence they may perhaps be divided into the following classes: 1. Conjunctions which unite either individual words, or phrases, or sentences, without, in the last case, implying any subordination of one sentence to the other. Such are the words: *and, or, nor;* or the double forms: *both—and—, either—or—, whether—or—, neither—nor—.* With respect to this class it may be useful to point out the great advantage which the Greek and more particularly the Latin language possessed in the variety of their forms for *and:* as *και, τε* in the former, *et, que, atque* or *ac* in the latter. This superiority over modern languages, simple as it is in itself, gave to the longest Latin sentence a perspicuity of arrangement, which in a great measure superseded the necessity for a cumbersome punctuation. (*Journal of Education*, vol. iv., p. 135.) 2. Conjunctions, which in themselves simply meaning *this*, being prefixed to a secondary sentence or phrase, direct the attention to that secondary phrase as a unit, and thus prepare it for subjection to some preceding word. This usage of the pronoun is as nearly as possible equivalent to the use of the bracket or vinculum in algebra, which connects the separate elements of any compound or polynomial term, and subjects it as a new unit to the algebraical operation, the sign of which is attached to the vinculum. Horne Tooke, in his remarks upon the so-called conjunction *that*, furnishes many examples: as, 'I wish you to believe that I would not willingly hurt a fly,' which is resolved by him into 'I would not willingly hurt a fly; I wish you to believe *that*.' A mathematician would have expressed it by 'I wish you to believe [I would not willingly hurt a fly],' where the words within the brackets must be considered as a compound accusative or object after the verb *believe*. The Latin *ut* and *quod* in their origin are merely neuters of the relative, and the original meaning of the relative, it must be recollected, was *this*. [ARTICLE.] Hence they too are used in the same way as the English *that;* for example: *suadeo ut abeas*, 'I recommend *this*, you should go away;' *lætatur quod redieris*, 'he rejoices at *this*, you have returned.' Other examples may be found in the use of the Greek ὁτι, which is again the neuter of a relative, as: λεγω ὁτι τεθνηκε, 'I say *this;* he is dead.' In Greek there is sometimes a double accusative after the verb, one of which simply denotes the object of the verb, and the other points to the condition or state of the object, as explained by the words that follow it: thus, ὁρω σε ὁτι κακως πασχεις, literally, 'I see you *this*, (that) you are suffering.' This employment of the pronoun is more particularly to be noticed after prepositions. Thus, in the Latin language, if a simple noun be the object of a preposition, all that is required is to put that noun in a certain case, as *post cœnam*, 'after dinner;' but if a verb with its accessories is to be subject to a preposition, it is common to interpose the vinculum *quam*, 'this,' as, *postquam cum fratre suo cœnaverat*, 'after he had supped with his brother.' Even in English we might say: 'after that he had,' &c. Examples of this usage are abundant in the forms *antequam, præterquam, extra quam, præter quod, prout;* and the word *this* is sometimes doubly expressed, as in *pro eo ut, ad-eo ut, propter-ea quod, ex eo quod, præter quam quod.* The German idiom agrees precisely with the Latin, as may be seen in *nach-dem, in-dem*, &c., as opposed to the employment of the simple prepositions *nach, in*, &c. The French, too, have their *pendant-que*, &c., *puis-que*, &c., and the English their *besides that*, &c., *now that*, &c., and the old phrase *being that*, &c. 3. The pronoun in the several languages thus employed as a vinculum is frequently attached as an enclitic to the preceding word, and grammarians, not observing the distinction between the governing word and the pronoun, have often given the name of conjunction to the compound, as *postquam* in Latin, διοτι in Greek, *puisque* in French, *nachdem* in German. 4. The vinculum, however, is not essential in those forms, and is therefore frequently omitted; but in case of this omission the governing word must immediately precede the phrase which is dependent upon it. This governing word, which expresses the nature of the connexion between the subordinate and the superior sentence, is also called a conjunction, but here the term is used in a different sense. The words which signify *this*, of which we previously spoke, found their claims to the title of a conjunction upon the fact that they unite the several elements which follow into a whole. When the governing particle is so called, it is because it binds the one sentence to the other. 5. There is a class of words which correlate with conjunctions: such as *so* in connection with *as* or *that, yet* with *although, therefore* with *since* or *because*. These words are often called adverbs, but as they too serve to connect sentences, they deserve like the rest the name of conjunctions. They bear, in fact, the same relation to the other conjunctions that the so-called antecedent does to the relative.

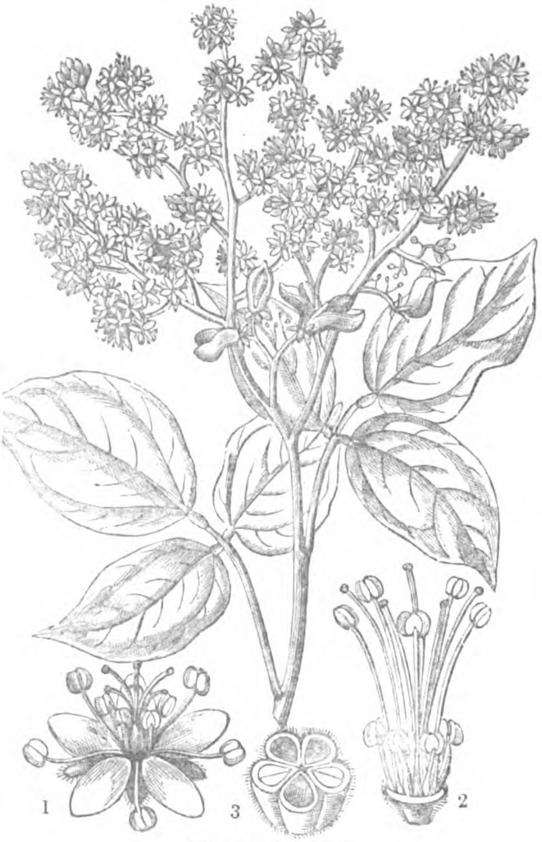
We have already said that conjunctions belong in their origin to all the leading parts of speech. Examples of verbs so employed are seen in the English *if*, formerly written *gif*, i. e. *give*. (Horne Tooke as before, p. 103, &c.) The Latin *licet*, 'although,' is evidently a verb signifying 'it is allowed.' So too *vel*, 'or,' appears to be an derivative of *volo*, 'choose;' and *si*, as well as the Greek ει, 'if,' have much resemblance to the imperative moods of the verb 'to be.' The English *while* and the Latin *dum* of the same meaning are substantives signifying 'time.' 'Either' and 'whether' are of course pronominal adjectives, and 'or' is a corruption from 'other,' as is evident from the German equivalent *oder*. And a similar analogy seems to lead to the derivation of the Latin *aut—aut*, from *alterum—alterum*. Conjunctions of a participial and prepositional character have occurred in the examples already quoted; but the relative form appears to be specially fertile in the production of this class of words, as, in the Latin, *quam, quando, quamquam, quamvis, ubi, unde, ut, quia, quod;* and the English *when, how, as, where*. In fact the relative itself has the power of a conjunction, as explained under the second head. [ARTICLE.]

Many of the conjunctions defy all attempts at analysis, and certainly Horne Tooke, notwithstanding the acuteness and truth of his general views, has occasionally erred in the details of derivation.

CONN, LOCH, a large lake, 3½ miles from Ballina, in the county of Mayo in Ireland; it is 11 miles in length, with a coast of 53 miles and a surface of 14,000 acres. It is situated 27 feet above the level of the sea at Killala Bay, in which it discharges its water through the river Moy. The water power which could be procured from Loch Conn is estimated at equal to half the power of all the steam-engines in Glasgow. Loch Conn is a double lake; its southern half is called Loch Cullin.

CONNAMARA. [GALWAY.]

CONNARA'CEÆ, tropical trees or shrubs, with pinnated alternate leaves having no stipules, polypetalous flowers having ten unequal hypogynous stamens, and a fruit consisting of one or more one-seeded follicles. Their seeds are remarkable for having the embryo at the end most distant from the hilum. The species are much alike in habit, not numerous, and possess no known properties that deserve to be mentioned.



[Connarus Asiaticus.]

An expanded flower, much magnified. 2. Its stamens and styles. 3. A section across the ovary.

CONNAUGHT, a province of Ireland, containing the counties of Galway, Mayo, Roscommon, Leitrim, and Sligo. It lies between 52° 52′ and 54° 25′ N. lat., and between 7° 33′ and 10° 15′ W. long. The latitude is about that of Yorkshire and Lincolnshire; but from its proximity to the ocean, the climate is much more moist and variable. It is bounded on the north and west by the Atlantic Ocean; on the east by the river Shannon and the counties of Cavan, Fermanagh, and Donegal; and on the south by the county of Clare. Clare was at one time a part of this province, to which it would appear naturally to belong; but it is now annexed to Munster. The greatest length of Connaught, from Scariff on the borders of Clare on the south, to Mullaghmore Head on those of Donegal on the north, is 85 Irish, or 108 English miles; and its greatest breadth, from the boundary of Leitrim on the N.E. to Slyne Head on the S.W., 93 Irish, or 118 English miles. It is estimated to contain 3,660,451 statute acres; but this calculation probably falls much short of the actual amount, which cannot be ascertained till the completion of the Ordnance Survey of Ireland, now in progress.

The mountain-ranges are distributed round the coast. From their inland declivities the province has a comparatively level surface to the Shannon. This river thus becomes the main drain of the intermediate country. Its chief feeders in Connaught are the Suck and the Gara; the latter discharges the waters of Loch Gara and Loch Key, and the former, a large river, is navigable from its confluence with the Shannon to Balliforan, a distance of about 20 miles. The streams which flow to the ocean are much more numerous, but the body of water brought down by them is not so great. They take their rise chiefly in lakes, which are distributed through the mountain districts of Galway and Mayo. Of these, Lochs Corrib, Mask, and Carra discharge their united waters southward by Galway; and Loch Conn, Loch Arrow, and Loch Gilly, northwards by Ballina, Ballasadera, and Sligo respectively. The rivers which flow westward from the lakes of Connamara and Erris are short and rapid in their course, and comparatively inconsiderable in the quantity of water; so that, with reference to its rivers, the province may be divided generally into three districts: that of the Shannon, that of the basin of Loch Corrib, and that of the basin of Loch Conn. The neighbourhood of Ballihannis in Mayo, about the centre of the province, forms the summit level from which these principal slopes diverge; and lines drawn from this point to Scariff on the south-east, Sligo on the north-east, and Westport on the west, will be found to mark pretty nearly the boundaries of each.

The limestone field of Connaught is very nearly co-extensive with the low district between the Shannon and the western elevations. The mountain-groups that inclose this plain present towards the inland field successive elevations of sandstone, clay-slate, granite, and quartz, corresponding pretty nearly with the development of the same strata on the opposite side of the island. The limestone field is very much encumbered with bog, which in Ireland is almost always found to rest on limestone gravel. An immense tract of ground in Galway, Roscommon, and Mayo, is thus rendered of little or no value; for the borders only of these bogs (some of them of twice the extent of the bog of Allan) are available for purposes of turbary. The remainder of the province is more mountainous than any other district of equal extent in Ireland; so that Connaught, in produce and population, is far behind the other provinces. An estimate may be formed of the condition of Connaught, as to religious and other instruction, by referring to TUAM. Its history, antiquities, and local description will be found under the heads of its separate counties.

Connaught was formerly a kingdom of the Irish Pentarchy. Its kings were of the race of O'Connor. It enjoyed a comparative independence until the year 1590, when it was made shire-ground under the 11th Eliz. c. 39, and divided into six counties, viz., those above enumerated and Clare, which had formerly been part of Munster. In 1602 Clare was re-annexed to the latter province, yet so late as 1792 remained on the Connaught circuit. In the various rebellions down to the end of the seventeenth century, Connaught was the refuge of the fugitive and dispossessed Irish. The Irish language is still very prevalent; and the condition of the poorer classes to this day attests the miserable circumstances which brought the population together. Employment is here more difficult to be obtained than in any of the other provinces. The average of wages is 7d. per day, and the average of employment for labourers is only 125 days in the year. Multitudes of the peasantry, especially from the counties of Mayo, Leitrim, and Sligo, annually emigrate in search of employment: a great part of every harvest of England and Lowland Scotland is reaped by these wanderers.

Numerous projects have been formed for the improvement of this province and the development of its great resources. It has been proposed to run a railroad from Dublin to Blackrod Bay on the western coast through the county of Mayo; and to Roundstone Bay in Connamara through the county of Galway; also to Sligo through the county of Roscommon, all by way of Athlone. Canals have also been proposed, as an extension of the Royal Canal to Loch Conn and Killala, and an extension of the Grand Canal from Ballinasloe to Loughrea. It is at present in contemplation to connect the lakes of Galway and Mayo, so as to form a line of navigation from Galway to Killala, through Lochs Corrib, Mask, Carra, Castlebar, Cullin, Conn, and the river Moy to Ballina, a distance of eighty miles, through a district susceptible of immense improvement. To con nect these lakes it would require a series of cuts only seventeen miles in length, the remainder of the navigation already existing in detached lakes and parts of rivers. The line of navigation would pass through a country abounding in limestone, marble, compact granite, sandstone flags, marl, and brick and potters' clay, with an inexhaustible supply of turf fuel, all which are at present valueless from not being accessible.

The produce of Connaught which comes to market consists chiefly in black cattle, which are sold in immense quantities at the fair of Ballinasloe. There is a pretty brisk export of grain from Sligo and Ballina, but, generally speaking, the resources of the province remain quite undeveloped.

The progress of population has been rapid, as will be seen from the annexed table. Still it falls far short of that of the island at large. In the number of houses and inhabitants to a square mile, Connaught bears to the other provinces a proportion of little more than 2 to 3.

Population of Connaught. *No Return under Act of* 1812.

CONNECTICUT, one of the United States of North America, is bounded on the south by Long Island Sound, which separates it from Long Island; by Rhode Island on the east; by Massachusetts on the north, and by the State of New York on the west. It has a sea coast of about ninety-five miles along the Sound, which is indented by several good harbours, of which New London, New Haven, Bridgeport, and Norwich, are the chief. The form of Connecticut is nearly that of a parallelogram, which is about eighty-five miles long from east to west, with a mean width of sixty miles from north to south. The area is about 5000 square miles, or about one-eighth less than that of Yorkshire.

Hartford, the capital, near the centre of the state, on the left bank of the Connecticut river, is in 41° 46′ N. lat., and 72° 45′ W. long. The surface of the country is generally uneven, but there are no lofty mountains. The principal ranges of high ground run from north to south in the direction of the Housatonick and the Connecticut, the two principal rivers of the state. The Lyme range on the east side of Connecticut river separates the lower basin of the Connecticut from the Thames. A range of high land of moderate elevation, called the Middleton Mountains, runs from Hartford on the Connecticut, past Middletown, to New Haven. The Housatonick mountains run along the western margin of the state, on the west side of the Housatonick river.

The Housatonick rises in Berkshire county, Massachusetts, in a fine plain 1000 feet above the sea, and running a general southern course through a picturesque valley, enters the Sound at Milford Point, after a course of about 120 miles.

The Connecticut, which is a considerable river, rises in Lower Canada, about 45° 20′ N. lat., and its sources are supposed to interlock with those of the Androscoggin, Kennebeck, Chaudiere, and St. Francis. Its general course is S. by W. and then S.W. to the point where it breaks through one of the Appalachian ranges, and receiving the Passamsick, descends over the Barnet falls from the high valley in which it hitherto flows, into a lower basin. From the junction of the Passamsick it continues, as it did before, to form the boundary between New Hampshire and Vermont, and after a course of about 140 miles, it is deflected for a short distance to the S.E. by some high land. Resuming its general southern course, it enters Massachusetts. Below the confluence of Miller's river (which joins it on the right bank in Massachusetts about twelve miles south of the boundary between New Hampshire and Massachusetts), the river again abruptly bends to the west a few miles above Greenfield. It makes several other bends in Massachusetts, which state it leaves about five miles below Springfield. Its general southern course continues to Middletown in Connecticut, where it is deflected to the S.E. by some high land, and continuing this direction it enters the Sound. The whole course of the river is probably not less than 400 miles. The Connecticut is in many respects a very remarkable river. Its general course, as already described, is nearly due S.: though it receives numerous streams, they are comparatively of small importance. The river basin above the junction of the Passamsick, is about thirty miles wide: below this point it widens to about forty; the whole surface of the basin is calculated at about 9300 square miles. The river generally flows in a deep and often narrow valley, bordered by high lands, which, where they recede from the river, leave fine alluvial plains. One of these alluvial plains stretches uninterruptedly for forty miles from a little above Middletown, in Connecticut, to South Hadley, in Massachusetts. The sources of the Connecticut lie in a region with a mean elevation of at least 1200 feet above the sea, and four degrees north of the outlet of the river in Long Island Sound. These circumstances cause a considerable contrast in the climate of the different parts of the Connecticut basin, and, combined with the circumstance of the narrowness of the river valley, help to account for the dreadful inundations to which the alluvial tracts on the river are exposed. In September, 1828, the river rose at Hartford twenty-four feet above low-water mark, and did immense damage. The river is navigable for vessels drawing ten feet water to Middletown, which is at the head of tidewater, and thirty-six miles from the Sound; vessels drawing seven feet and a half ascend to Hartford, fifteen miles above Middletown. Though this river is much obstructed by rapids, falls, and shoals, it has been made navigable for boats of considerable size to the Fifteen Mile Falls in New Hampshire, a total distance of 250 miles.

The only canal in the state that is yet completed, is the Enfield canal, five miles and a half long, which was made to avoid the falls of the Connecticut. The Farmington canal, which is to connect Northampton in Massachusetts, with New Haven in Connecticut, will be seventy-eight miles long, when completed.

The soil of Connecticut is only of a medium quality, except in the river valleys, some of which contain rich alluvia. Agriculture is generally in a good state, and the pastures on the low lands are particularly fine. The minerals are iron, copper, lead, cobalt, plumbago, and coal.

The state is divided into eight counties, subdivided into 120 townships: the population is 297,675. Hartford, on the Connecticut, near the centre of the state, has a population of near 10,000. Newhaven, which stands on a bay on Long Island Sound, has a considerable trade, and a population of about 10,700. The legislature meet alternately at Hartford and Newhaven. Middletown, on the Connecticut, has manufactures of cotton, woollen, and arms, and a population of about 6900. New London, at the mouth of the Thames, with a population of about 4400, has some vessels engaged in the whale fishery. Norwich, with a population of about 5200, is a manufacturing town.

Yale college, in Connecticut, which is an old foundation, has a president and fourteen professors and tutors, with a library and a large collection of minerals. There is also a law and medical school connected with the college. Washington College, at Hartford, was founded in 1826. Hartford also contains a very well regulated asylum for the deaf and dumb. The Wesleyans have a university at Middletown. The State of Connecticut possesses large resources for education. The interest of the school-fund, which amounts to 2,000,000 dollars, is appropriated to the support of elementary schools.

---

* Exclusive of the town of Galway, not calculated.

The legislative body is composed of a senate, consisting of twelve members, and a house of representatives, consisting of 208 members. The present constitution was adopted in 1818, up to which time the state was governed by the colonial charter granted by Charles II. in 1662. Connecticut sends six members to the House of Representatives at Washington, and two senators to the Senate.

CONNELL, SIR JOHN, was admitted an advocate of the College of Justice in the year 1788, and soon afterwards married the daughter of President Campbell. In March, 1796, he was made sheriff of Renfrewshire, and on Mr. Robertson's elevation to the bench he was elected procurator to the church of Scotland, May, 1806. In the end of the year 1815 he published the first edition of his 'Treatise on Tithes,' and in July following was advanced to be judge of the admiralty in Scotland. In May, 1818, he published his 'Treatise on Parishes,' and had afterwards the honour of knighthood. In July, 1830, the high court of admiralty and his office of judge-admiral were abolished by act of parliament. He died suddenly the following year.

CONNOR, a bishop's see in the archdiocese of Armagh, in Ireland; the chapter consists of dean, chantor, chancellor, treasurer, archdeacon, and four prebendaries. This diocese is very nearly co-extensive with the county of Antrim. It extends in length from N. to S. 57 miles, and in breadth from E. to W. 30½ miles. It contains 72 parishes, constituting 47 benefices: of these parishes, three and a part of a fourth are in the county of Derry, and a part of one is in Down. In 1792 the numbers were—76 parishes, 40 benefices, and 43 churches of the Establishment. In 1834 the numbers were—churches of the Establishment, 51; Roman Catholic ditto, 45; Presbyterian ditto, 96; and other houses of Protestant and Dissenting worship, 41. In the latter year the gross population of the diocese was 361,618; of whom there were 66,888 members of the Established Church; 95,545 Roman Catholics; 193,261 Presbyterians; and 5924 other Protestant Dissenters; being the proportion of one member of the Established Church, and three Presbyterians and Dissenters, or four Protestants of whatever denomination, to $1\frac{4}{9}$ Roman Catholics; or as $2\frac{7}{9}$ to 1 nearly, from which it appears that Connor is the most Protestant diocese in Ireland. There were at the same time in this diosese, 562 schools, educating 32,938 young persons, being in the proportion of $9\frac{11}{100}$ per cent. of the entire population under daily instruction, in which respect Connor stands tenth among the 32 dioceses of Ireland. Of these schools, 86 were in connexion with the Board of National Education, being in the proportion of one to six and a half.

Connor, from which the diocese takes its name, is an inconsiderable village situated on the Glenwhippy river, in the barony and county of Antrim. It was a place of some note in 1315, at the time of the invasion of Edward Bruce, by whom it was taken, after the defeat of the English under Richard, Earl of Ulster, before its walls. It is supposed to have gone to decay after the irruption of the expelled Irish in 1333. There are now no traces of an episcopal seat; a large Presbyterian meeting-house is the chief object in the village.

The bishopric of Connor was founded by Aengus, the son of Nissa, usually known as Saint Macnish, who died A. D. 514. He was the disciple of Olcan, who was the disciple of Patrick. Of his successors little is known until the time of Malachy O'Morgair, who was advanced to this see A. D. 1124. Prior to this time the diocese had fallen into a very barbarous state.

Its inhabitants are represented by Bernard of Clarevalle, who has written the life of Malachy in Latin, as being 'Christians in name, but Pagans in practice; caring neither for the rites of marriage nor of baptism; paying neither tithe nor first fruits; in fine, little better than beasts of the field.' Yet, such was Malachy's success in reclaiming them, that on his translation to the see of Armagh, in 1134, he is said to have left this diocese, which he had found sunk in iniquity, engaged in the practice of all the virtues. At this time the diocese was known indifferently as Connor and Dalnaruigh, or Dalaradia. Shortly after we find Reginald, bishop of Connor, subscribing witness to a charter of John De Courcy, the conqueror of Ulster. In the beginning of the fifteenth century the diocese appears to have relapsed into a barbarous condition: numbers of the people were without baptism; and one family, the clan Gillmore, of which Hugh Mac Adam Mac Gillmore was the chief, being in a state of civil and ecclesiastical outlawry, committed many atrocious sacrileges. Mac Gillmore himself is said to have destroyed no less than forty religious houses. He was at length put to death, 1407, by a party of the clan Savage, in the Franciscan Church at Carrickfergus, where he had taken sanctuary. Soon after, in 1442, one John, being bishop of this diocese, prevailed on Pope Eugene IV., contrary to the wishes both of the Irish primate and the court of England, to unite the sees of Down and Connor, which have so continued ever since. By the 3rd and 4th William IV., c. 37, sec. 121, the united bishopric of Down and Connor becomes augmented by the diocese of Dromore.

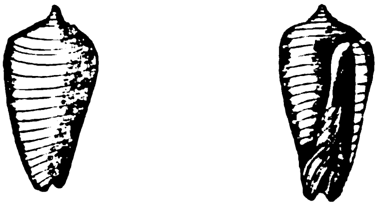
(Ware's *Bishops*; Beaufort's *Memoir of a Map of Ireland; Reports of Commissioners.*)

CONODYCTIUM. [POLYPIARIA MEMBRANACEA.]

CONOELIX, CONŒLIX, or CONOHELIX, a genus of turbinated shells, established by Mr. Swainson for a group which, in his opinion, 'form a beautifully defined link connecting the *Cones* with the Volutes, strictly so termed'—with the following generic character. 'Shell conform. Spire very short. Outer lip simple. Columella or pillar plaited. Aperture linear, narrow, longer than the spire. Generic type, Conœlix lineatus.' (Swainson.)

The animal, which is doubtless a gastropod, is not known.

Geographical Distribution.—Mr. Swainson (*Zoological Illustrations*) figures three species, and mentions that several specimens are in the Banksian collection from the Pelew islands. To one of these species in that collection, Taheite, usually called Otaheite, is given as a locality. Mr. Cuming brought home another species, *C. Virgo*, which Mr. Swainson considers as representing *Conus Virgo*, from the reefs at the island of Rietea. It was in shallow water. Mr. Swainson says, in the work above quoted, that Mr. Humphrey informed him that he had at different times seen five or six other species besides those figured by Mr. Swainson, all of small size. Example. *Conoelix lineatus*. 'Shell smooth, whitish, with transverse capillary fulvous lines. Spire depressed, the apex prominent. Pillar six-plaited. Inhabits the South Seas?' (Swainson.) The figures, which are of the natural size, are copied from the accurate drawing in the *Zoological Illustrations*. All the other known species are comparatively small.



[Conoelix lineatus.]

De Blainville divides the genus *Mitra* into five sections, and makes his fifth consist of 'Imbricaria, Schum., and Conœlix, Sow.,' meaning Sowerby; but the genus is Swainson's, and is generally adopted.

CONOID (like a cone), a term sometimes applied, but in this country only, to the surface generated by the revolution of a conic section about its axis. [SPHEROID, HYPERBOLOID, PARABOLOID.]

CONON (Κόνων), an Athenian general, was the son of Timotheus. The first time he is mentioned in history is B.C. 413, in the eighteenth year of the Peloponnesian war, when he had the command at Naupactus on the Corinthian gulf. (Thucyd. vii. 31.) Conon was the chief of the ten generals who were appointed to the command of the Athenian fleet, when Alcibiades and Thrasybulus were removed from office, and, though at first beaten in a sea-fight by Callicratidas [CALLICRATIDAS] the Lacedæmonian general, he afterwards gained a signal victory at Arginusæ. Lysander being appointed a second time to the command of the Spartan fleet, engaged with Conon at Ægospotami, and defeated him, B.C. 405. Immediately dispatching to Athens the sacred ship Paralus with the news of the defeat, Conon himself fled to Salamis in Cyprus, where the friendship of the king, Evagoras, sheltered him from the obloquy or punishment which he would have encountered at home.

Isocrates has given us a pleasant picture of the intimacy which subsisted between the Athenian general and the

Prince of Salamis during Conon's residence in Cyprus. Here for a time he kept aloof from action, watching attentively the progress of affairs: the negotiations, which he soon commenced with the Persian satrap Pharnabazus, terminated in a speedy union of the Persian and Athenian forces with those of Evagoras, with the view of stopping the progress of the Lacedæmonians. Evagoras, Conon, and Pharnabazus together, raised a powerful fleet, in the command of which Pharnabazus was materially assisted by the experience of Conon. Falling in with the enemy's fleet near Cnidos, they gained a complete victory, B.C. 394: the galley of the Spartan general, Peisander, being driven on shore, most of his crew escaped; but Peisander disdained to save himself by flight, and was killed on board his ship. The consequences of this victory were of great importance to the interests of Athens; and Isocrates (*Philip.* §§ 94, 95) represents Conon as having completely destroyed the Lacedæmonian empire. Of the Grecian islands, some surrendered at once, and others showed a readiness to renew their old alliance. This was a juncture too favourable to be lost sight of, and accordingly Conon and Pharnabazus hastened to follow up their success by an invasion of the Thracian Chersonese. Town after town submitted to them, and the people abandoned their lands. Sestos and Abydos still held out, but the approach of winter at last put an end to the attempt at reducing them, and the satrap and Athenian admiral began to prepare for the operations of the ensuing spring, at the commencement of which they proceeded without delay to the coast of Laconia, and ravaged the country in various parts, B.C. 393. Conon seized the opportunity, which the flush of their present success afforded, for obtaining from Pharnabazus many important favours for his country. The satrap allowed him the use of his fleet for recovering the payment of tribute from the islands, and not only gave a large sum of money towards the rebuilding of the long walls at Athens, which had been demolished by the Spartans at the close of the Peloponnesian war, but sent men to assist in the work. At this time Conon appears to have returned to Athens, amidst the joy and congratulations of his countrymen: his portrait, which with that of Evagoras was placed beside the statue of Zeus Soter, was a slight memorial of their gratitude.

At the time when Antalcidas was sent on an embassy from Sparta to conclude a peace with the Persian king, Conon, the Athenian ambassador, was one of those who refused to give their assent to such terms as were proposed for their acceptance. The result was that he was imprisoned by the Persian minister Teribazus, on pretence of his adopting measures detrimental to the great king. What became of him afterwards we have no certain information. Nepos says, that according to some he was brought up before the king himself and put to death; while others affirm that he escaped from confinement. Xenophon, who relates his imprisonment, says nothing of his death. Lysias (*On the Property of Aristophanes*, §§ 635-646) gives an account of Conon's property, which was of considerable amount in Cyprus, and states that it was disposed of after his death; and Mitford (chap. xxv. § 6) has conjectured with good reason, that he escaped to Cyprus out of the hands of Teribazus, and died there. The words of Lysias (§ 640) certainly imply that he died a natural death, and was not murdered. He appears to have died about B.C. 388. (Clinton, *Fast. Hel.*) He had a wife in Cyprus at the time of his death. (Isocrates and Lysias, as cited above; Xenophon, *Hellenica*, i. 4-7; iv. 3-8; Diodorus Siculus, xiii. 48, 77, 78; xiv. 39, 79, 83, 84, 85, 86; Nepos, *Life of Conon;* Plutarch, *Life of Lysander*, and of *Artaxerxes*.)

CONON, of Alexandria, a friend of Archimedes, mentioned in his writings as having a great knowledge of geometry. He was the proposer of the spiral which bears the name of Archimedes. [SPIRAL OF ARCHIMEDES.]

CONOVULA. [MELAMPUS.]

CONRAD I., count of Franconia, was elected king of Germany A.D. 911, on the death of young Ludovic IV., the son of Arnulf, and the last of the Carlovingian dynasty in Germany. He was chiefly engaged during his reign in making his authority respected by the turbulent dukes or great vassals, his electors; among whom Henry, duke of Saxony and Thuringia, was the most powerful and most troublesome. The Huns too attacked Germany, and pushed their depredations as far as Bavaria. Conrad went to oppose them, and received a mortal wound in battle, A.D. 919. In his last moments he exhibited a wise policy. Knowing the ambition and power of Duke Henry, he recommended to his brother Eberhard and his other relatives the propriety of renouncing their own views, and of electing the Saxon duke; a measure which he looked upon as necessary to the salvation of Germany. His advice prevailed, and Henry, called the Fowler, was elected after his death by the title of Henry I. Conrad was never crowned emperor or king of Italy, the Italians having chosen a separate king, Berengarius, marquis of Friuli.

CONRAD II., called the Salic, duke of Franconia, was elected king of Germany after the death of Henry II., A.D. 1024. He annexed the vast dominions of Burgundy to the German confederation, forced the king of Poland to do homage for Silesia, and ceded the duchy of Schleswig to Canute, king of Denmark, as a fief, on the same condition. The great feudal nobles of Italy were at variance among themselves and with the towns. They had acknowledged the princes of the House of Saxony for their kings, and Conrad their successor crossed the Alps to enforce a like submission. He was crowned king of Italy at Monza by Heribert, archbishop of Milan, in 1026, after which he convoked a general diet of Lombardy in the plain of Roncaglia, near the Po, not far from Piacenza. In this diet he regulated the feudal legislation of Italy, the jurisdiction of the great feudatories, the successions, &c. He then proceeded to Rome, where he was crowned by Pope John XIX. as emperor and king of the Romans, with the titles of Cæsar and Augustus, A.D. 1027. Gisela, Conrad's wife, was crowned empress at the same time. Two kings, Rudolf III. of Burgundy and Canute of Denmark, were present at the ceremony. On Conrad's return to Germany, he was obliged to repress the insubordination of the great vassals.

Rudolf of Burgundy having died in 1033, the crown of that kingdom devolved upon Henry, Conrad's son, and Rudolf's nephew by his mother; but it was not without a war that Conrad secured his son's inheritance. About 1035 there was a general rising in Lombardy of the vassals, or sub-feudatories, against the great lords, secular and clerical, and especially against the archbishop of Milan. A battle was fought between Milan and Lodi, in which the archbishop was defeated, and the bishop of Asti was killed. In 1036 Conrad came down into Italy with an army to quell the disturbances; he deposed Heribert and imprisoned him, but the people of Milan rose in favour of their archbishop, and resisted all the forces of the emperor. During the two years that Conrad passed in Italy he visited Rome and Monte Casino, deposed Pandolfo, prince of Capua, and gave the principality to his brother. A pestilence having spread among the imperial troops in 1038, Conrad returned into Germany, and in the following year died at Utrecht. He was succeeded by his son, Henry III.

CONRAD III., of the House of Hohenstauffen, Duke of Franconia, and nephew of Henry V., was elected king of Germany in 1138, after the death of Lotharius II., who had succeeded Henry. Conrad had already been proclaimed king of Italy during the life of his uncle. Henry the Proud, of the House of Welf, Duke of Saxony and of Bavaria, who had married Lotharius's daughter, and whose sway extended from the Baltic to the Alps, had also pretensions to the imperial crown. Conrad, assembling a diet at Würzburg, stripped Henry both of Bavaria, which he bestowed on Leopold V., margrave of Austria, and of Saxony, which he bestowed on Albert the Boar, who was descended from the antient dukes of that province. A civil war was the result: Henry the Proud preserved Saxony, but dying in the midst of the war, his rights descended to his infant son Henry, afterwards styled the Lion. Welf, brother of Henry the Proud, expelled Leopold from Bavaria. A battle was fought at Winsberg in Suabia, between Welf and Conrad, which was lost by the former, and is memorable as having given rise to the distinctive names of Guelphs and Guibelines, which became the rallying words of two opposite parties that desolated Germany and Italy for centuries. At the battle of Winsberg, the war cry of the Saxons and Bavarians was that of their leader 'Welf;' and that of the imperial troops was 'Waiblingen,' a town of Würtemberg, the patrimonial seat of the Hohenstauffen family. The two names were originally applied to the respective adherents of the Saxon duke and of the emperor; but that of Welf soon became extended to all the rebels or disaffected to the imperial authority. The Italians, adopting the distinction long after, named Guelphs all the opponents, and Guibelines the supporters, of the imperial authority in Italy. Owing to the constant jealousy between the church and the empire, the popes and their adherents were generally found on the side of the Guelphs. For the moment however peace was made in Germany: Henry the Lion was acknowledged Duke of Saxony, and gave up Bavaria to the margrave of Austria. Albert the Boar was indemnified for the loss of Saxony by the erection of Brandenburg into an independent margravate, which his own successes over the Sclavonic tribes bordering on the Baltic soon raised to an equal rank with Saxony, Bavaria, Suabia, and the other great provinces of the empire. Having thus given peace to Germany, Conrad was induced by the preaching of St. Bernard to assume the cross. He set out with a numerous host for the East, by the way of Constantinople. In conjunction with Louis VII. of France, he penetrated into Syria, and besieged Damascus and Ascalon, but without success. Conrad having lost most of his followers, returned disappointed to Germany, which he found again distracted by the intrigues of Welf. He defeated Welf, and died in 1152, as he was preparing to set out for Italy to receive the imperial crown from the hands of the pope. He was succeeded by his nephew, Frederic of Hohenstauffen, Duke of Suabia, surnamed by the Italians 'Barbarossa.'

CONRAD IV., son of Frederic II. emperor of Germany, and king of Italy and of Sicily, was elected king of the Romans in his father's life time; but at the death of Frederic, A.D. 1250, he found a competitor for the crown of Germany in the person of William of Holland, who was supported by all the influence of Innocent IV. The pope excommunicated Conrad, as the son of the excommunicated Frederic, and released all his subjects of Germany and Italy from their allegiance. This was an epoch of the greatest animosity in Italy between the Guelphs and the Guibelines. The popes were bent on the destruction of the house of Hohenstauffen, the great leaders of the Guibelines, and who had stoutly resisted the universal temporal sovereignty which was assumed by the see of Rome. Naples, Capua, and other towns of Apulia and Sicily, revolted against Conrad, but Manfred, the natural son of Frederic, who had been left regent of the kingdom in the absence of his brother, brought back most of them to their allegiance, and laid siege to Naples.

In 1251 Conrad, on arriving in Italy, was well received by the Guibeline party, which was strong in Lombardy, especially at Verona, Pavia, Cremona, Piacenza, Tortona, Pistoia, and Pisa. In 1252 Conrad passed into Apulia, and on receiving the oath of allegiance from many of the barons, he asked the pope for the investiture of the kingdom of Sicily and Apulia; but the pope maintained that all Conrad's rights were forfeited through the rebellion of his father against the authority of the church. Conrad, strengthening his army with the Saracen colonists who had been removed from Sicily by his father and settled in Apulia, at Lucera, and in the neighbourhood, took Naples after an obstinate defence, and razed the walls of that town. Meantime the pope was offering the crown of Sicily, first to Richard of Cornwall, afterwards to Edmund III., son of Henry Crookback, of England, and, lastly, to Charles count of Anjou, who accepted it. In 1254, while Conrad was preparing to return to Germany to oppose William of Holland, he was taken ill at Lavello, in Apulia, and died soon after. The Guelphs spread a report that Manfred had poisoned him in order to possess himself of the crown of Sicily and Apulia, as they had already accused him of having hastened the death of his father Frederic; but these reports are deserving of little notice. [Manfred.] Conrad left one only son, called also Conrad, who, on account of his tender age, was styled by the Italians Conradino, or little Conrad. Berthold of Hohenburg was left tutor of the young prince, who was brought up in Germany, and Manfred remained regent of the kingdom of Sicily and Apulia in the name of his nephew. For the Guibeline version of all those transactions, see Raumer's *Geschichte der Hohenstauffen*, and for the Guelph part, the numerous Italian writers, and Sismondi's *Histoire des Républiques Italiennes*.

CONRADIN, CONRADI'NO, son of Conrad IV. and of Elizabeth of Bavaria, was an infant when his father died in 1254. He was acknowledged as duke of Suabia, but his father's splendid inheritance of Sicily and Apulia passed into the hands first of Manfred and afterwards of Charles of Anjou, by the battle of La Grandella, A.D. 1265, in which Manfred was killed.

In the autumn of 1267 Conradin, when only 16 years of age, set out for Italy at the head of a few thousand men. At Verona he was well received by the great Guibeline leaders of N. Italy. He entered Rome without opposition, the pope being then at Viterbo, and thence took the road of the Abruzzi. He met his opponent, Charles, at Tagliacozzo, near the lake of Celano, on the 23rd of August, 1268. The battle was long contested; the Germans had at first the advantage, and, elated with success, were pursuing the French, when Charles, who had been lying in wait, came up with his reserve and completely routed them. Conradin escaped from the field of battle with his cousin Frederic Duke of Austria and others, and descending from the mountains reached the village of Astura, on the sea coast near the Pomptine marshes, expecting to find some means of reaching the fleet of his allies the Pisans, which was in the neighbourhood. But John Frangipani, Lord of Astura, seized upon him and delivered him up to Charles for a sum of money. He was taken to Naples, tried, and, notwithstanding the protest of a celebrated jurist, Guido da Luzzano, and others, he was condemned and beheaded in the market-place on the 29th October, 1268, together with Frederic of Austria and several of their followers. The story of the glove, said to have been thrown down by Conradin from the scaffold, to be delivered to Peter of Arragon, the husband of Constance, daughter of Manfred, does not seem sufficiently authenticated. A chapel was raised on the place of the execution. The chapel no longer exists; but in the vestry of the new church of Santa Croce al Mercato, built opposite to it, is a small column of porphyry, which once stood on the very spot of the scaffold, with a Latin distich commemorative of the event. (Valéry, *Voyages en Italie*.) Conradin's mother hastened from Germany to ransom her son. Coming too late, she used the money in founding the great convent Del Carmine, where the remains of Conradin and Frederic of Austria were deposited behind the great altar.

CONSALVI, E'RCOLE, CARDINAL, born at Rome in June, 1757, studied for the church, but applied himself likewise to belles lettres, music, and the arts. He became a monsignore, or prelate attached to the papal court, and was made, by Pius VI., Uditor di Ruota, or member of the highest civil court of the Roman State. When Cardinal Chiaramonti became pope he made Consalvi, whom he knew and appreciated, a cardinal deacon, with the title of Santa Maria ad Martyres, in August 1800, and appointed him at the same time his secretary of state or first minister.

In 1801 Consalvi repaired to Paris, and concluded the concordat with the first consul, Bonaparte. His pleasing manners and liberal opinions procured him marked attention during his stay in the French capital. In 1806, when Bonaparte began to quarrel with the pope, he insisted upon Consalvi being removed from his office, under the pretence that he was ill affected towards him, which meant in reality that he defended the interests and rights of his own sovereign. Consalvi himself urged the pope to accept his resignation for the sake of peace. Pius at last unwillingly received it, and appointed Cardinal Casoni his successor. Consalvi remained at Rome during the following years until the abdication of the pope in 1809. After that event he was exiled from Rome with the other cardinals, but some time afterwards he was allowed to join the Pope at Fontainebleau. On the release of the pope, and his return to Rome in 1814, Cardinal Consalvi was reinstated in his office of secretary of state, and continued the presiding minister of the court of Rome till the death of Pius, 20th August, 1823. Consalvi did not long survive his master and friend, to whom he had been faithfully attached through all the vicissitudes of a long and stormy pontificate, and between whom and him there was a sympathy of mind and a mutual confidence. [Pius VII.] Cardinal Consalvi died at Rome in 1824. He was buried in the church of S. Marcello, where a monument was raised to him by the sculptor Rinaldi. An excellent full-length likeness of him by Sir Thomas Lawrence is in the king's collection of paintings.

Consalvi's administration of the papal state forms an epoch in the history of modern Rome. He abolished numerous abuses and old customs which were no longer in accordance with the state of society. He was favourable to rational change. By the Motu Proprio of 1816 all feudal taxes, monopolies, and exclusive rights were suppressed. Torture, and the punishment of the corda or estrapade, the use of which had long disgraced the most frequented street of Rome, were likewise abolished, as well as the punishment of death for the indefinite and undefinable offence of heresy. A new civil code, a commercial code, and a penal code were ordered to be framed. The maintenance of the registry of mortgages, introduced by the French, a better system of police, having in its service a respectable body of carabineers or gendarmes, instead of the old worthless sbirri, and the establishment of workhouses for the poor in the principal towns; all these are the results of Consalvi's administration. He also took strong measures to extirpate the banditti from the Campagna, and in one instance, July, 1819, he ordered the town of Sonnino, one of their notorious haunts, to be razed to the ground. New concordats were entered into with France, Naples, Bavaria, and other German states. (*Compendio Istorico sù Pio VII.*, Milano, 1824; *Biografia degl' Italiani viventi*, art. 'Consalvi;' and Tournon, *Etudes Statistiques sur Rome.*)

CONSANGUINITY, or KINDRED, in law, is the relation subsisting between persons who are of the same blood, or, in other terms, who are descended from the same stock or common ancestor. Consanguinity, in this sense, is either *lineal* or *collateral*. The former subsists between persons who are related to each other in the direct ascending line, as from son to father, grandfather, great grandfather, &c.; or in the descending line from great grandfather to grandfather, father, and son. Collateral kindred are those who, though they have the same blood, derived from a common ancestor, and are therefore *consanguinei*, do not descend one from the other. Thus brothers have the same blood and are descended from a common ancestor, but they are related to each other collaterally, and the children and descendants of each of them are all collateral kinsmen to each other. The Canon Law and the Civil Law have adopted different methods of computing the degrees of collateral consanguinity. According to the former, which has been followed by the law of England, we begin at the common ancestor and reckon downwards to the persons whose degree of consanguinity we desire to ascertain, counting each generation as a degree; and the degree of consanguinity in which they stand to each other is the degree in which both of them, or the more remote of them, stands to the common ancestor. Thus (to use the example given by Sir William Blackstone), Titius and his brother are related in the first degree; for from the father to each of them is counted only one; but Titius and his nephew are related in the second degree, for the nephew is two degrees removed from the common ancestor; viz., his own grandfather, the father of Titius. On the other hand, in this supposed case, the civilians would place Titius and his nephew in the third degree of consanguinity, for they count all the degrees from one given person upwards to the common ancestor, and downwards from that common ancestor, whose degree of relationship to the first person it is the object to establish. Thus they would count from Titius's nephew to his grandfather two degrees, and one more from the grandfather to Titius. By the law of England, all persons related to each other by consanguinity or affinity, nearer than the fourth degree of the civil law, are prohibited from marrying, excepting in the ascending or descending line (in which the case is hardly possible by the course of nature); and by stat. 5 and 6 William IV., c. 54, sec. 2, it is enacted, 'that all marriages celebrated after the date of that Act between persons within the prohibited degrees of affinity or consanguinity, shall be absolutely null and void to all intents and purposes whatsoever.' Under the statute of distributions, 22 and 23 Car. II., c. 10, in making the distribution of an intestate's personal estate among the next of kin, the computation of degrees of kindred is according to the Civil Law. (*Novell.*, 118, and INTESTACY; Blackstone's *Essay on Collateral Consanguinity*, and Blackstone's *Commentaries*, vol. ii., p. 202.)

The question of consanguinity is the question of relation between two given persons, as explained above. If one of these persons is called $\boxed{\text{A}}$, all his lineal ancestors will be found in (*a*) in the ascending line above him, and all his lineal descendants in the descending line below him. His collateral relations will be found in the parallel lines (*b*), (*c*), (*d*), &c. The Roman numerals denote the respective degrees of consanguinity in the Canon, and the Arabic those in the Civil Law. Thus, III. in the ascending line is A's great grandfather, and III. in the descending line his great grandson. In the ascending and descending lines the computation of the civil and canon laws, as already explained, is the same: in both laws the great grandfather and great grandson are respectively in the third degree from A. No. III. in line (*b*) is A's great uncle, who, according to the mode of reckoning already explained, is in the third degree of consanguinity to A by the canon law; and in the fourth, as denoted by the Arabic numeral 4, placed under III., by the civil or Roman law.

The following are the names for consanguinity in the Roman law. In line (*a*) ascending from A: 1, pater, mater; 2, avus, avia; 3, proavus, proavia; 4, abavus, abavia; 5, atavus, atavia; 6, tritavus, tritavia: all above 6 are included in the general name 'majores.' In line (*a*) descending from A:—1, filius, filia; 2, nepos, neptis; 3, pronepos, proneptis; 4, abnepos, abneptis; 5, atnepos, atneptis; 6, trinepos, trineptis: all below 6 are included in the general name of 'posteri' or 'posteriores.'

In line (*b*), beginning with 2 and ascending:—2, frater, soror; 3, patruus, amita (uncle and aunt on the father's side); avunculus, matertera (do. on the mother's); 4, patruus magnus, amita magna, avunculus magnus, matertera magna; 5, propatruus, proamita, proavunculus, promatertera; 6, abpatruus, abamita, abavunculus, abmatertera.

In line (*b*), beginning with 3 and descending, the names are, 3, fratris, sororis, filius et filia, and so on.

In (*c*), beginning with 4 and ascending:—4, consobrinus, consobrina, which are the general terms, but properly signify those born of two sisters (quasi consororini); sons born of two brothers are properly called fratres patrueles: daughters, sorores patrueles. 5, propior or prior sobrino, propior sobrina, the sons and daughters of the patruus magnus, amita magna, &c. (See Tacit. *Annal.*, xii., 64.)

Some of the Latin writers used 'nepos' to express a brother's or sister's son.

It is unnecessary to go farther. (*Institut.* iii. tit. 6, *De Grad. Cognationum.*)

CONSCRIPTION is the name given to the mode of recruiting the French army. Under the old monarchy the army was recruited chiefly by voluntary enlistment, and the soldiers were taken mostly from the peasantry, by whom the change from the condition of a daily labourer to that of a soldier was considered as an improvement. The officers were appointed from among the higher or educated classes. When the revolution commenced, the old army was broken up, the whole nation was called to arms, and volunteers were found in abundance. But as the soldiers were bound by no permanent obligation, a system of requisition was enforced, by which every district was bound to furnish a certain number of men for the regular army. But even this proved insufficient, and the Executive Directory found itself in want of soldiers to supply the numerous armies on the frontiers. In 1798 General Jourdan presented to the Council of Five Hundred a project of a law for a new mode of recruiting, under the name of conscription. This project was approved by the legislature, and passed into a law 5th of September, 1798. After setting down as a principle that every Frenchman is bound to defend his country when in danger, the law went on to say, that independently of danger to the country, every Frenchman from the age of twenty to twenty-five is liable to be called out to serve in the regular army. Every year lists were made in every department of the young men of the age above stated, divided into five classes, the first being those between twenty and twenty-one years; the second from twenty-one to twenty-two; and so forth. The number of men required for that year being made known by the Government, and voted by the legislature, a distribution was made among the departments and districts of the quota which each was to furnish. The number required was then taken by lot from the first or junior class, and when that was exhausted, from the second, and so on. This operation was repeated every year. The first levy by conscription in 1799 was 200,000 men. Bonaparte, when First Consul, found the system already established, and he applied himself strenuously to render it more effective, and carry it to the utmost extent. At the beginning of 1802 a levy was made of 120,000 conscripts, 60,000 of whom were to fill up vacancies in the army on the peace establishment, and the other 60,000 to form a reserve in case of war. In April, 1803, 120,000 more conscripts were levied out of the conscription lists for the years XI. and XII. In October of the same year, 60,000 more were levied out of the lists of the year XIII. By an arrêté 19 Vendemiaire, year XII. (12 October, 1803), severe penalties were enacted against refractory conscripts, that is, those who had not joined their regiments. Eleven depôts in various citadels were marked out for them, where they were to be kept under arrest, and work at the fortifications. They were also condemned to a fine, payable by their relations. In January, 1804, 60,000 men of the list of the year XIV. were levied. On this occasion, Bonaparte said to the Council of State that the law of the conscription was the dread and desolation of families, but that it formed the security of the state. (Thibaudeau, tome v. p. 319.) In 1805, just before the war of Austerlitz, a Senatus Consultum ordered a levy of 80,000 men. Till then the levies had been voted by the legislative body, but henceforth a Senatus Consultum was deemed sufficient.

In December, 1806, a levy was ordered of 80,000 men; in 1808, 80,000, besides 80,000 more of the conscription lists of 1810, to be called out in 1809. This was on account of the Spanish war, which the senate said was 'politic, just, and necessary.' Instead of men of twenty years complete, according to the original law, the young men now taken were not nineteen. In 1809, a new Senatus Consultum, 18th April, ordered a levy of 40,000; and on the 5th October, another of 36,000. In 1810 there was a levy of 120,000 of the lists of 1811, besides 40,000 conscripts of the maritime departments for the service of the navy. In 1811 the levy was 120,000 conscripts, besides those levied in Tuscany, the Roman states, Holland, and the Hanseatic towns recently annexed to the empire. As the levies increased, the repugnance of young men to the service became greater, and the severity of the government against refractory conscripts increased in proportion. A reward of twenty-five francs was given for seizing one. When there was a considerable number of refractory conscripts in a department, a moveable column was formed to hunt after them, and the soldiers were quartered in the houses of the relations of the fugitives, who were obliged to board them.

The disasters of the Russian campaign occasioned new expedients for raising men besides the regular conscription. Half a million of men was voted by the senate towards the end of 1812, consisting of 150,000 conscripts of 1813, 150,000 of 1814, 100,000 out of the lists of 1809, 1810, 1811, and 1812, who had not been included in the former levies, and 100,000 men of the first ban of the National Guard, who were formed into regiments of the line.

In November, 1813, another Senatus Consultum placed at the disposal of the emperor 350,000 more conscripts of the lists of 1813-14, who had not been included in the previous levies; and by a decree, 17th December of the same year, 180,000 men, taken chiefly from the National Guards, were ordered for the defence of the towns, as the allies threatened the French territory. And yet, notwithstanding these enormous calls, Napoleon, in 1814, had hardly 150,000 regular troops to oppose to the allies.

Besides the above conscriptions of the French empire, the kingdom of Italy furnished the following numbers:—in 1805, 6000; January, 1807, 9000; October, 1807, 10,000; 1808, 12,000; 1810, 11,000; January, 1811, 15,000; November, 1811, 15,000; 1812, 15,000; February, 1813, 15,000; October, 1813, 15,000.

Few soldiers, unless disabled by infirmities or wounds, ever got their discharge under Napoleon. The time of service was unlimited. By the present law of France, the harshness of the conscription, the principle of which, though not the name, is retained, has been greatly mitigated, and the soldier is entitled to his discharge after five years' service. Greater facility is allowed for procuring substitutes, which Napoleon admitted in principle, and even defended in the Council of State, as necessary 'in the present state of society, which was very different from that of Sparta or Rome;' but he afterwards surrounded it with so many difficulties, that substitutes became extremely scarce and expensive. Exemptions are also granted to the single sons of poor parents, and upon other humane considerations, as well as in cases of delicate health of young men applying to the learned professions, &c.; all which considerations were entirely overlooked in the sweeping conscriptions of the empire. A system somewhat similar to the conscription exists in Prussia and other German states. [PRUSSIA.]

CONSECRATION (consecratio), the act of sanctifying or making holy, consists in the solemn appropriation or dedication of anything to the service of the Deity. In modern times the consecration of men is usually called *ordination*, except in the case of kings and bishops, when the performance of the rites of sanctification is still named consecration. When applied to temples, churches, and altars, it is generally termed *dedication*. It is sufficient to advert to the religious antiquities of India, Egypt, Judæa, Chaldæa, Greece, Rome, and of the Celtic Druids in Britain and Europe in general, to show the antiquity of consecration. At the commencement of the Mosaic dispensation all the first-born of man and beast were consecrated to the Lord. (*Exodus* xiii., 2, 12, 15.) Subsequently the whole tribe of Levi was thus consecrated instead of the first-born (*Numbers* iii., 12, 45; viii., 16, 18); and Aaron and his sons, who were Levites, were more especially consecrated to the priest's office. (*Exodus* xl., 13.) The dedication or consecration of the tabernacle and altar is described in the book of *Numbers* ch. vii. Of the dedication of the first or Solomon's Temple, a description is given in 1 *Kings* viii., 5; and of the second temple in *Ezra* vi., 16. Under the Jewish theocracy not only men and beasts were consecrated to the Lord, but houses, fields, and the walls of Jerusalem. (*Leviticus* xxvii.; *Nehemiah* xii., 27.) At the commencement of the fourth century, when Christianity, under Constantine, became the established religion of the Roman state, and Christian temples began to vie in magnificence with those of the Pagan deities, they were consecrated with great pomp; for instance, the church of Jerusalem, built by Constantine over the supposed site of the Holy Sepulchre, when the ceremony was performed by a full synod of all the bishops of the east. (Euseb. *Ecc. Hist.*, l. 10, c. 45. Gratian, *Concordantia Discordantium*, part 3.)

The following are the principal parts of the rite of consecrating a church according to the Roman Catholic pontifical. Previous to the ceremony three crosses are painted on each wall of the church, and over each cross is placed a lighted candle. The bishop, in his pontifical vestments, proceeds to the church door, attended by his clergy reciting the seven penitential psalms; and after a solemn procession round the external walls, which are copiously sprinkled, in the name of the Trinity, with a kind of brush dipped in consecrated water, the bishop knocks loudly at the door with his pastoral staff, repeating from the 23rd Psalm, 'Attollite portas, et introibit Rex Gloriæ;' to which a deacon, who is within the church, replies, 'Quis est iste Rex Gloriæ?' The bishop responds, 'Dominus fortis et potens, Dominus potens in prælio,' &c.; then signing the door with the figure of the cross, he exclaims, 'Ecce crucis signum! fugiant phantasmata cuncta.' On the admission of the bishop and clergy the *Veni Creator* is chanted, and ashes are strewn on the floor in the form of a cross, in which the bishop, with his staff, traces some alphabetical characters. After several prayers the altar is consecrated by sprinkling it with a mixture of water, wine, salt, and ashes, in the name of Jesus Christ; the solemnity closes by depositing in the altar a vessel containing relics and incense, with a parchment inscribed with the name of the bishop and the date of the consecration. The church, on this occasion, is richly decorated, and the altar is illumined with a profusion of large tapers. (Broughton's *Hist. Dic.*, vol. i., p. 311.) Churches are not recognised as such by the law of England until they are consecrated by a bishop. The form used by the Church of England is given at length in Bishop Gibson's 'Codex juris Ecclesiastici Anglicani,' pp. 1459-1463: see also Bishop Wilkins's 'Concilia Magnæ Britanniæ,' vol. iv. p. 668, and Burn's 'Eccles. Law, Churches,' sec. 2. The present form has been used since 1712; and in 1799 it was adopted, with some slight modification, by the episcopal church in America. One of the principal charges on which Archbishop Laud was arraigned before the Commons was, that he endeavoured to revive the Roman Catholic ceremonies in the consecration of churches and altars, with all their costly furniture. Still the Protestant form of consecration, as well as the Catholic, is an imposing ceremony; and the 21 stat. Henry VIII., c. 13, states as the reason for allowing a bishop six chaplains, that this number is requisite for the consecrating of churches. The village feasts which are still celebrated in many parts of England commence on the anniversary day of the consecration of the parish church, and are said to have been substituted by Pope Gregory the Great for similar festivities appertaining to the Druidical religion. (Bingham, b. 8, c. 9). Consecration is generally understood to change not the nature of the thing consecrated, but merely the *use* of it; and in this opinion the Catholics appear to acquiesce, with regard to numerous objects which they usually consecrate; as church bells, candles, water, oil, crosses, pictures, &c. But with respect to the consecration of the eucharistic bread and wine, they maintain that a complete change is effected in the thing consecrated,—the body and the blood of Jesus Christ, by the change of the bread into his body, and of the wine into his blood, being believed to be really present by virtue of the words of consecration. This is what is termed transubstantiation. (Brunet, *Parallèle des Religions*, 4to., 1792, tome iii., p. 310; *Exposition de la doctrine de l'Eglise Catholique, par* Bossuet.)

The consecration of animals was very common in antient Egypt, where birds, beasts, and reptiles were privileged, as in modern India, to live unmolested, and even to receive adoration. Athenæus and Ælian speak of sacred fishes, adorned with necklaces; so the sacred crocodile in Egypt was decorated with ear-rings. (Herodotus, ii. 69.) Consecration is a name given to the apotheosis of the Roman emperors, and coins and medals commemorating these events have the inscription CONSECRATIO. See an account of these funeral honors in the article APOTHEOSIS, and the medal with the legend CONSECRATIO in the article AURELIUS.

CONSERVATOR OF THE STAPLE, in the law of Scotland, an officer in the nature of a foreign consul, resident at Campvere, in the Netherlands. By the Act 1503, c. 81, passed, as the preamble states, for the welfare of merchandize, and to provide remedy for the exorbitant expense of pleas in foreign courts, the conservator of Scotland was vested with a jurisdiction to do justice between merchant and merchant in the parts beyond sea, such merchants being the king's lieges, and the conservator exercising his jurisdiction by advice of at the least four merchants, his assessors; and it was further provided by the Act, that no Scotch merchant sue another before any other judge beyond sea, nor do in the contrary of the statute, under the penalty set down therein. By subsequent Acts he was empowered to put the usury laws and other like laws in execution among the same merchants; so that the conservator might be regarded as a commercial judge, with a civil and criminal jurisdiction over native Scotsmen beyond the realm.

From the chapter immediately following that first above cited, wherein the conservator is required to come yearly home, or send a procurator for him, to answer all matters laid to his charge, we might suppose that appeal lay from him only to the king and council. But since the erection of the Court of Session, in 1532, he has been regarded as an inferior judge, and his court as an inferior court, which it is accordingly considered by Erskine in his 'Institutes,' b. i., tit. 4, sec. 32. In the case of Hoy *v.* Tenant, June 27, 1760, the Court of Session went still farther, and held itself as the *forum originis* of all Scotsmen, to have a cumulative jurisdiction with the conservator.

CONSERVATORS OF THE PEACE, before the comparatively modern institution of justices of the peace, were officers who by the common law of England were appointed for the preservation of the public peace. These conservators, whose powers were far inferior to those of modern justices of the peace, consisting almost entirely of the authority to take sureties for the peace and for good behaviour, were of several kinds. In the first place, certain high functionaries were general conservators by virtue of their offices. Thus the king, the lord chancellor or lord keeper, the judges of the court of King's Bench, and the master of the rolls, were intrusted by the common law with the general conservancy of the peace throughout the realm, as incidental to their several offices. Other officers again were conservators only in special places; thus the judges of the common pleas and barons of the exchequer were conservators of the peace only within the precincts of their several courts. In like manner, judges of assize and gaol-delivery within the places limited by their commissions; coroners and sheriffs within their several counties; the steward of the Marshalsea within the verge of the king's household; and constables and tithingmen within their hundreds or tithings, were all conservators of the peace at common law; and all the officers above enumerated retain their authority at the present day. But besides these official conservators there were others who were expressly intrusted with the charge of the peace, either by prescription, election, or tenure. Thus it is said that the owner of a manor might have prescribed that he and his ancestors, whose estate he had, were entitled to be conservators of the peace within such manor. So also as sheriffs were formerly elected, and as coroners still are elected, by the freeholders of the county, certain persons were, before the reign of Edward III., elected conservators of the peace in different counties. There were also instances in which lands were granted by the king to hold of him by knight's service, and also by discharging the duties of conservation of the peace within the county where the lands lie. Besides these, there were conservators of the peace appointed by letters patent from the crown, in cases of emergency, to defend particular districts, where breaches of the peace were apprehended in consequence of foreign invasion or intestine tumult. All the different kinds of conservators of the peace above noticed, excepting those who have the duty cast upon them as incidental to other offices, were entirely superseded upon the establishment of the system of justices of the peace, in the early part of the reign of Edward III. [JUSTICES OF THE PEACE.] (See also full details upon this subject in Lambard's *Eirenarcha*, book i., cap. 3.)

CONSERVATORY. The names given to the garden buildings employed for preserving plants in an artificial climate, are applied with so little precision, that it is almost a matter of indifference which to select for the purpose of explaining the principles that ought to be observed in the construction and management of such houses. We shall therefore reserve for the article GREEN-HOUSE what we have to say upon that head, and briefly dismiss the others as their names occur. In illustration of this remark we may observe that the term conservatory, which, as its meaning shows, was originally intended for buildings in which plants were preserved during winter, has come to be used, firstly for glass-houses in which plants are cultivated by growing them in the open border, and subsequently for all such glazed buildings whatsoever. A conservatory, properly so called, is a brick building heated by artificial means, having its whole southern part closed by large glazed sashes, which may be opened or shut at pleasure. Its floor is generally of stone, and a part of it is occupied by a stage on which plants in pots can be placed. One of these buildings, but in a ruinous state, may be seen in the physic garden at Chelsea; others are not uncommon in gardens that were laid out forty or fifty years ago, but they are fast falling into neglect and disuse—in our opinion undeservedly. Such a conservatory was intended to preserve during the winter orange-trees, myrtles, American aloes, and similar plants, which during the summer will flourish in the open air, but which require in winter to be protected against the inclemency, or, to speak more exactly, against the cold and wet of the English climate. Such plants are torpid during winter; their rest begins with that of our trees, and it is easy to prevent a renewal of their growth at too early a time; to preserve them against too much wet and from severe cold, especially in the spring, is all that is requisite for them, and these objects the old conservatory answered perfectly well. It had moreover the advantages of being spacious without being excessively costly; of being easily heated, and of requiring the smallest possible amount of labour for the plants preserved in it. Persons however, gradually forgetting the original object of a conservatory, added to it numerous species requiring a very different treatment in winter from those it was contrived for; and what was far worse, they attempted by humidity and high temperature to keep the plants in a growing state all the winter. The necessary consequence of this was, that those plants which formerly succeeded in the conservatory became unhealthy, the new comers disappointed the expectations of their cultivators, and the building itself fell into discredit. The reason of this is sufficiently obvious. Plants when in a growing state require an abundant supply of light: a conservatory is particularly ill calculated, on account of its solid roof and sides, for the admission of light, and consequently a conservatory is not suitable for plants in a growing state; but plants when torpid, as in their winter season, require a very moderate supply of light, and this a conservatory is sufficiently calculated to admit.

A house of this kind is best suited for gardens of considerable extent, where a large number of plants is required during the summer for the ornament of the flower garden and shrubbery. Under such circumstances we strongly recommend the erection of conservatories as the cheapest, the most efficient, and the most ornamental mode of preserving in a healthy state during winter not only oranges, myrtles, and similar plants, but in general all the species which are natives of countries that, without experiencing severe frost, are cold enough during winter to suspend the vital energies of vegetation. It will be perfectly within the gardener's power to keep the earth in which conservatory plants grow sufficiently damp during winter to enable them to accumulate by the return of spring an abundant supply of new sap; and this is all that he need be particularly reminded of, if he understands his business scientifically; if he does not, advice to him would be only a waste of words. [GREEN-HOUSE.]

CONSISTORY is the court christian, or spiritual court, formerly held in the nave of the cathedral church, or in some chapel aisle or portico belonging to it, in which the bishop presided, and had some of his clergy for assessors and assistants. But this court is now held by the bishop's chancellor or commissary, and by archdeacons or their officials, either in the cathedral church or other convenient place in the diocese, for the hearing and determining of matters of ecclesiastical cognizance happening within that diocese. (Burn's *Ecclesiastical Law*, tit. *Consistory.*)

By stat. 24 Henry VIII., c. 12, an appeal lies from this court to the court of the archbishop of the province.

CONSOLS, a term familiarly used to denote a considerable portion of the public debt of this kingdom, more correctly known as the three per cent. consolidated annuities. This portion of the debt originated under an Act 25 Geo. II., whereby various perpetual and lottery annuities then outstanding, and which from the time of their creation had respectively borne an interest of 3 per cent., were brought under one head in the public accounts. Various additions have from time to time been made to the amount of these annuities; and, on the other hand, some diminution has been effected by the operation of the sinking-fund and the application of surplus revenue. The capital outstanding and unredeemed under this head, on the 5th of January, 1836, amounted to 356,768,258*l.* 4*s.* 6*d.*, and the annual interest or annuity to 10,703,047*l.* 14*s.* 11*d.*

CONSONANCE, in Music, a term which has, we think, often been explained with too strict a regard to its etymological meaning. That it signifies *one sound heard with another* is undeniable, but the two sounds must, in our opinion, be concords. [CONCORD.] *Consonance* and *dissonance* are words which, in music, ought to be considered as synonyms of *concord* and *discord.*

CONSONANT. [ALPHABET, p. 379.]

CONSPIRACY. Every conspiracy to do an unlawful act which is injurious to individuals or to the public, is a misdemeanor at the common law of England. Many frauds affecting individuals, which cannot be made the subject of prosecution as such, become indictable when they are effected by the co-operation of several confederates. Thus where several persons agree by indirect means to impoverish a third person, as by circulating calumnies injurious to his character or credit, the offence is punishable as a conspiracy, though the concerted acts alone, when committed by individuals, could only have formed the subject of a civil action by the injured party. Another instance of this is, the case of a conspiracy among journeymen or servants to raise the price of wages, by refusing to work under a certain price. Any individual may fix what price he pleases upon his labour, and may lawfully refuse to work under that price; but if he conspires with others to do the same thing, he may be indicted for a conspiracy at common law In former times, persons convicted of conspiracy at the suit of the king (the nature of which offence is very doubtful), were liable to receive what was called *villanous* judgment, by which they were rendered incapable of acting as jurors or witnesses, their lands and goods were forfeited for life, and their bodies committed to prison. This judgment was never however inflicted upon persons convicted of conspiracies of a less aggravated kind at the suit of the party; and in modern times, the villanous judgment having become obsolete by long disuse, the punishment of conspiracy has been by fine, imprisonment, and sureties for good behaviour, at the discretion of the court. (Russell *on Crimes and Misdemeanors*, vol. ii.)

CONSTABLE. This word is supposed by Ducange, Spelman, Cowell, and other legal etymologists, to be corrupted from *comes stabuli*, which was another name for the *tribunus stabuli* or *prepositus equorum*, a kind of master of the horse, frequently mentioned as an officer of state in the middle ages. (See Ducange's *Glossary*, ad vocem *Comes Stabuli.*) Sir Edward Coke, Selden, and several other writers, insist upon another etymology—from two Saxon words, *koning*, a king, and *stapel* or *stabel*, a stay or support—*quasi columen regis*. Both these derivations are equally remote from the description of the office of our modern constable; but the former appears to be far the more probable; and, in accordance with it, the Constable of France was an important officer of the highest rank in that country, who had the chief command of the army, and had judicial cognizance of military offences; and whose duty it was to regulate all matters of chivalry, such as tilts, tournaments, and feats of arms. This office was suppressed in France by an edict in the year 1607; it was revived by Napoleon, and constituted one of the six grand dignities under the French empire; and was finally abolished upon the restoration of the Bourbon dynasty in 1814.

Immediately after the Norman conquest, we find in England an officer of the crown called the Lord High Constable, whose duties, powers, and jurisdiction were in most respects strictly analogous to those of the Constable of France. The office was one of great dignity and power, both in war and peace, the constable having the command of the army and the regulation of all military affairs. He was the supreme judge of the court of chivalry, in which character his encroachments upon other courts were so heavy a grievance in early times, that the stat. 13 Rich. II. c. 2 was passed to restrict his jurisdiction to 'contracts and deeds of arms and things which touch war, and which cannot be discussed or determined by the common law.' The office, for several centuries after the Conquest, passed by inheritance in the line of the Bohuns, Earls of Hereford and Essex, and afterwards in the line of their heirs-general, the Staffords, Dukes of Buckingham, in right of certain manors held by them by the feudal service of being constables of England. The fees of the office were extremely burdensome to the crown; and the possession by a subject of the hereditary right to command the militia of the realm, independently of any royal appointment, was an unusual and frequently a dangerous power; and on this account Henry VIII., in the early part of his reign (1514), consulted the judges respecting the means of abolishing the tenure. He was advised by them, that as the individuals holding the manors were only compellable to exercise the office *ad voluntatem regis*, he had the power of discharging the feudal service altogether; and acting upon this opinion, the king abolished the office, by disclaiming to have the services any longer executed. (See Dyer's *Reports*, p. 285 b.) The effect of this was, that Edward Stanley, the last duke of Buckingham in that line, the hereditary high constable of England at the time of this resolution, held the manors after this period discharged of the service of being constable. All doubt which might have been suggested respecting the legal extinction of the office by this means, was removed eight years afterwards by the attainder of the Duke of Buckingham for high treason, upon which even the manors in question were forfeited to the crown. Since that time, the office of high constable has never been granted to any subject, excepting *pro hâc vice*, upon great and solemn occasions, such as the king's coronation or trials of peers.

'Out of this high office,' says Lambard, in his 'Duties of Constables,' 'the lower constableship was first drawn and fetched, and is (as it were) a verie finger of that hand; for the statute of Winchester, which was made in the time of Edward I., and by which the lower constables of hundreds and franchises were first ordained, doth, amongst other things, appoint that, for the better keeping of the peace, two constables in every hundred and franchise should make the view of armour.' He then concludes, in justification of his etymology of the term, that 'the name of a constable in a hundred or franchise doth mean that he is an officer that supporteth the king's majesty in the maintenance of his peace.' This derivation of the office of a common constable seems very improbable, especially as it is the better opinion that these officers were known to the common law before the statute of Winchester. (See Hawkins's *Pleas of the Crown*, book ii. cap. 10.) An ancient judicial authority, chief justice Fineux, in the reign of Henry VII., gives a more reasonable account of the matter. He says that when the superintendence of the peace of a county was found too great a task for the sheriff, hundreds were formed, and a conservator of the peace under the sheriff appointed in each, who was called a constable. This was the high constable, or constable of the hundred. In process of time, as population increased and towns grew into existence, it was found expedient to make a further subdivision for the preservation of the peace; and accordingly, conservators were appointed for manors, vills, and tithings, who were then called petty constables. (See *Year Book*, 12 Henry VII. pl. 18.)

Following this account of their origin, which is confirmed by many of the minute incidents of the two offices, constables, in the usual acceptation of the term at the present day, are of two kinds; constables of hundreds, who are still called high constables, and constables of vills or tithings, who are called either petty constables or tithingmen. Both high and petty constables were formerly chosen by the jury at a court leet, and were sworn in and admitted there by the lord or his steward; but at the present day the high constables are usually chosen by the magistrates at the quarter-sessions. The petty constables are still often chosen by the homage at the court-leet; but by the stat. 13 and 14 Car. II. c. 12, s. 15, it is enacted, that if any constable shall die or go out of the parish, any two justices shall make and swear a new constable, until the lord of the manor shall hold a court, or until the next quarter-sessions, who shall approve of them or appoint others. By virtue of this statute, and by reason of the disuse of courts-leet in modern times, the duty of nominating and swearing the constables is now generally discharged by the justices of the peace.

By the Metropolitan Police Act, 10 Geo. IV. c. 44, the police force are appointed by direction of the Secretary of State, and sworn in as constables by the commissioners; and in boroughs affected by the provisions of the Municipal Reform Act (5 and 6 Will. IV. c. 76), constables are now appointed by the Watch Committee under the authority of the 76th section of that statute. The office of constable at common law is a yearly appointment; and if any officer has served longer than a year, the justices at quarter-sessions will, upon his application, discharge him, and appoint another officer in his stead.

Besides these general constables, two or more justices of the peace, upon information that disturbances exist or are apprehended, are authorized by the stat. 1 and 2 Will. IV. c. 41, to appoint special constables; and by the 83rd section of the Municipal Reform Act, magistrates in boroughs are authorized to swear in as many inhabitants as they think fit to act as special constables when called upon.

In general, all the permanent inhabitants within a district, borough, parish, or place, are liable to serve as constables; but they must be persons of good character and of competent ability; and the lord or steward of the manor at the leet, or the justices, may exercise a discretion as to the appointment of proper persons. It is obligatory upon a constable who has been legally appointed to serve the office, unless he can show some lawful exemption; and if he refuses to serve, he may be fined or punished by indictment. The following persons are exempt from serving the office; namely, members of the colleges of physicians and surgeons in London, apothecaries in London, or within seven miles thereof, who are free of the Apothecaries' Company, and also those in the country who have served seven years' apprenticeship (see stat. 6 and 7 Will. III. c. 4); practising barristers, attorneys, dissenting ministers following no trade or other employment for their livelihood except that of a schoolmaster, and publicans.

The Metropolitan Police Act and the Municipal Reform Act contain provisions that the constables to be appointed under those statutes respectively 'shall have all such powers and privileges, and be liable to all such duties and responsibilities as any constable has within his constablewick by virtue of the common law of this realm.' In consequence of these provisions, it becomes of great practical importance to ascertain with precision the common-law incidents of the office of constable.

1. By the common law, constables are said to have been conservators of the peace; and in consequence of this character probably every constable has undoubted authority to arrest all persons who commit an affray, assault, or breach of the peace *in his presence*, and keep them in safe custody until they can be brought before a magistrate. It is said also by antient authorities that by virtue of his power as a conservator of the peace, he may himself, on view of a breach of the peace, take surety of the peace by *bond*, though he cannot do so by recognizance, being incompetent to administer an oath. But as his duty is to preserve the peace, and not to punish for the breach of it, it is doubtful whether he can arrest by his own authority and without a warrant, upon the information or charge of a third person, for an affray committed in his absence. (See the case of 'Timothy *v.* Simpson,' 1 Crompton, Meeson, and Roscoe's *Reports*, p. 760.) By sect. 9 of the Metropolis Police Act, and by sect. 79 of the Municipal Corporation Reform Act, constables appointed under those acts are expressly authorized, in charges of petty misdemeanor in the night time, to take bail by recognizance for the appearance of the offender before a magistrate within a limited time.

2. A constable having reasonable cause to suspect that a felony has been committed, may arrest and detain the supposed offender until he can be brought before a magistrate to have his conduct investigated; and he will be justified in so doing even though it should afterwards appear that in fact no felony was committed. In this case there is a distinction between the authority of a constable and that of a private person; the former may arrest if he can show a reasonable ground of suspicion that a felony has been committed; but a private person, in order to justify himself for causing the imprisonment of another, must prove, in addition to the reasonable suspicion of the individual, that a felony has actually been committed. A constable is bound to arrest any person whom he sees committing a felony, or any person whom another positively charges with having committed a felony; but generally speaking, he has no authority to arrest for a misdemeanour, either upon his own reasonable suspicion or the charge of another person, without a magistrate's warrant. With respect to the authority of a constable to arrest for felony or breach of the peace, Mr. Justice Buller is reported to have said, that 'if a peace-officer, of his own head, takes a person into custody on suspicion, he must prove that such a crime was committed; but if he receives a person into custody on a charge preferred by another of felony or breach of the peace, then he is to be considered as a mere conduit; and if no felony or breach of the peace was committed, the person who preferred the charge alone is answerable.' Lord Ellenborough, in the case of Hobbs *v.* Branscomb, (3 Campbell's *Reports*, 420,) said that 'this rule appeared to be reasonable.'

3. Constables were authorized by the common law to arrest such 'strange persons as do walk abroad in the night-season.' (See Lambard's *Constable*, p. 12.) This authority, which was perhaps sufficiently definite in times when the curfew was in practice and when watch and ward were kept, is at the present day of so vague a nature, that a

peace-officer could scarcely act under it without imminent danger of an action in every particular instance. It is however obviously essential to the efficiency of any system of police, that constables should be armed with some general authority of this nature, especially in towns. By the 7th section of the Metropolis Police Act, it is provided that 'any man belonging to the police force appointed under that act, may apprehend all loose, idle, and disorderly persons whom he shall find disturbing the public peace, or whom he shall have just cause to suspect of any evil designs, and all persons whom he shall find between sunset and the hour of eight in the forenoon lying in any highway, yard, or other place, or loitering therein, and not giving a satisfactory account of themselves, and deliver them to the constable in attendance at the nearest watch-house, to be secured until they can be brought before a magistrate.' The Municipal Reform Act contains a similar but less comprehensive provision, authorizing 'any constable appointed under that act, while on duty, to apprehend all idle and disorderly persons within the borough whom he shall find disturbing the public peace, or whom he shall have just cause to suspect of intention to commit a felony.' Besides these specific authorities, however, which apply only to the metropolitan police district and the boroughs affected by the Municipal Reform Act, there is no doubt that in general a constable, by virtue of his common law authority, may stop any person carrying by night a bundle or goods under circumstances of reasonable suspicion; and if upon examining him his suspicions are not removed, he may detain him in his custody. A constable has also a general authority to apprehend for offences against the Vagrant Act, 4 and 5 George IV., c. 83, or against the Larceny Act, or the Malicious Injuries Act, 7 and 8 George IV., c. 29 and 30.

4. In the execution of a warrant a constable acts no longer as a conservator of the peace, but as a ministerial officer to the magistrate who signs it. He is the proper officer to a justice of the peace, and is bound by law to execute his warrants, and may be indicted for disobeying them. It is his duty to execute the warrant of a magistrate as soon as it comes to his hands; and where he arrests or distrains or does any other act, though it is not absolutely necessary by law that he should show his warrant, he ought always to give notice of it, and he will be wise to produce it in all cases where it is demanded; but as the warrant constitutes his justification, he is not required to part with it out of his possession. If the constable has a legal warrant to arrest for felony, or even breach of the peace, he may break open doors after having demanded admittance and given notice of his warrant; and if, after such notice, he is resisted and killed, it will be murder. If a warrant be directed to a constable by his name of office merely, he is *authorized* by the Stat. 5 George IV., c. 18, to execute it out of his own constablewick, provided it be within the jurisdiction of the magistrate who signs it; but he is not *bound* to do so, and may in all cases make his election whether he will go beyond his own precincts or not.

5. The law has made several provisions for the indemnity and protection of constables in the proper discharge of their duty. Thus by the Stat. 7 Jac. I., c. 5, if an action be brought against a constable for any thing done by virtue of his office, he may plead the general issue and give the special matter in evidence; and if he recovers, he is entitled to double costs. Formerly if a magistrate granted a warrant in a matter over which he had no jurisdiction, the officer who executed it was liable to an action of trespass for so doing; but by the Stat. 24 George II., c. 44, s. 6, it is enacted, that 'no action shall be brought against any constable for anything done in obedience to the warrant of a justice of the peace, until he has neglected or refused to show his warrant on being demanded so to do. And if after he has shown his warrant, any action is brought against the constable alone, without joining the justice who signed the warrant, the defendant, on producing the warrant at the trial, shall be entitled to a verdict, notwithstanding the defect of the justice's jurisdiction; and if the action be brought against the constable jointly with the justice, the constable is to be entitled to a verdict on proof of the warrant.' By the 8th sect. of the same statute, all actions against constables for anything done in the execution of their office must be brought within six months. For the further protection of constables, the Stat. 9 George IV., c. 31, sect. 25, enacts that persons convicted of assaults upon peace-officers in the due execution of their duty may be imprisoned with hard labour for two years, and be fined or required to find sureties for keeping the peace.

For the guidance of the metropolitan police force, the commissioners deliver to each of the men printed directions, which contain an accurate and perspicuous summary of the laws relating to the duties, liabilities, and indemnities of constables. In those boroughs which have adopted a new system of police under the Municipal Reform Act, similar codes of instruction have been issued to the constables. (For fuller information upon the whole of this subject, see Viner's *Abridgement*, Bacon's *Abridgement*, and Burn's *Justice*, title 'Constable.')

CONSTABLE, LORD HIGH, OF SCOTLAND. In the twelfth century we find

Hugh de Morvill, of the family of the De Morvilles, barons of Burgh, co. Cumberland, contemporary with one Edward, Conestabulus; himself constable of Scotland, and the possessor of vast estates in Teviotdale, Lauderdale, Lothian, Clydesdale, and Cuninghame. He died anno 1162, when his son,

Richard de Morvill succeeded him in his possessions and high office. On his death, anno 1189, he was succeeded by his son,

William de Morvill, who died, anno 1196, without issue.

Helen, his eldest sister, being married to Roland, lord of Galloway, the latter became constable in her right, and lord of Cuninghame; and on his death, anno 1200, the office passed to their son and heir,

Alan, lord of Galloway[*]. He died, anno 1234, leaving only female issue; of whom was

Helen, his eldest daughter, who being the wife of Roger de Quincy, earl of Winchester, the latter became constable in her right. He died, anno 1264, leaving, by the said Helen, daughters only; of whom

Margaret, married to William de Ferrariis, earl of Derby, was the eldest. It is said that William de Ferrars, of Groby, their son, was some time constable. But the countess retained the office, and then resigned it into the king's hands, in favour of

Sir Alexander Comyn, earl of Buchan, lord justiciar of Scotland, the husband of Elizabeth, her immediate younger sister; and on his death the office fell to his son and heir,

John Comyn, earl of Buchan, who was forfeited in the year 1308 for his adherence to the Baliol interest.

Sir Gilbert de Hay, of Errol, was then made constable of Scotland during pleasure; and in 1311 the office was bestowed on

David de Strathbogie, earl of Athol, in like manner during pleasure; but he being soon afterwards outlawed for espousing the cause of Baliol,

Sir Gilbert de Hay, before mentioned, got the office in fee and heritage in the year 1314; since which time the constable's staff, then put into his hands by Bruce, has remained in the Errol family.

The office and jurisdiction of the lord high constable of Scotland differ from those of the like officer in England. No formal distribution of the powers of the lord justiciar of Scotland, such as took place at the breaking up of the aula regis of England, was ever made in the former kingdom; nor when in the course of years this happened, did the once large powers of the justiciar pass to the like officers in the one country as in the other. On the new modelling of the judicial polity of England by King Edward I., the constable and mareschal were set over a court of chivalry, with jurisdiction in matters of honour and arms. But in these, the constable of Scotland never had jurisdiction. His jurisdiction was of the nature of that in England, vested by 33 Henry VIII. c. 12, in the lord steward of the king's household, or (in his absence) of the treasurer, comptroller, and steward of the marshalsea; for according to the Leges Malc. II., he judged jointly with the mareschal in all transgressions committed within certain limits of the king's court. But even this jurisdiction seems to have been exercised in fact by the lord justiciar; the constable only protesting against the interference with his powers. In the reign of King Charles I. a commission was issued to inquire into the nature and extent of the constable's jurisdiction; and they reported that it extended to all slaughters and riots committed within four miles of the king's person, or of the parliament or privy council. No alteration was made at the Union; and by the act 20 Geo. II. c. 43—which swept away so many other heritable jurisdictions—the office and jurisdiction of the lord high constable of Scotland were expressly reserved.

---

[*] He is mentioned in the charter granted at Runnymede by King John of England. Selden calls him 'Alan de Leweia [which is an evident error for Galweia], constabular. Scotiæ,' Selden, 'Eng. Epin.' c. 10.

CONSTANCE. [CONSTANZ.]

CONSTANCE, COUNCIL OF, was assembled in 1414 at the request of the emperor Sigismund, chiefly to put an end to the great schism, during which John XXIII., Gregory XII., and Benedict XIII., each claimed the rank and office of sovereign pontiff. The Council deposed all three, and elected Ottone, cardinal Colonna, as legitimate pope, by the name of Martin V. It was on this occasion that a canon or decree was passed, asserting the supremacy of a general council over the pope. Gregory and John XXIII. submitted to this decision, the latter after much demurring; but Benedict continued the schism in Spain to the time of his death. The Council was also engaged in the trial of John Huss, who was summoned and appeared before it, and was arrested by order of the Council, notwithstanding a safeguard from the emperor. His doctrines were condemned as heretical, and as he would not retract he was publicly degraded from his priestly office, and then consigned to the civil magistrates, who by order of the emperor had him burnt. For the peculiar doctrines of Huss, some of which concerned doctrine, and others discipline, see HUSS. The Council condemned likewise the doctrines of Wycliffe, most of which were identical with those of Huss. Jerome of Prague, a disciple of Huss, having been brought before the Council, first retracted his obnoxious doctrines, but being still kept in prison, as his retractation was not considered to be sincere, he demanded a public audience, at which he declared that he had recanted only through a temporary weakness, and that he persisted in his master's doctrines; upon which he was also condemned to the stake, to which he went with the greatest serenity. Poggio Bracciolini, who was present at the tragical scene, bears full evidence, in his letter to Aretino, to the firmness of the victim; and so does Æneas Sylvius, afterwards Pope Pius II., in his 'Historia Bohemica.'

The Council had promised to occupy itself with a reform of church discipline, which was much wanted in that age; but it did little in that way, having been abruptly dissolved by the new pope, Martin V., in April, 1418. The Council of Constance is one of the most noted in the history of the church, and was one of the most numerous ever assembled. Lenfant has given a full and instructive account of all its proceedings, session after session. (*Histoire du Concile de Constance*, 2 vols., 4to., Amsterdam, 1727.)

CONSTANS, son of Constantine, had for his portion at his father's death, Italy, Africa, and Illyricum. His elder brother Constantine, being envious of his share, attacked him, was defeated, and killed near Aquileia, A.D. 340; after which Constans took possession of his brother's dominions, and became emperor of the whole west. Magnentius, commander of the troops in Gaul, having revolted against him, and drawn a great part of Gaul into his party, Constans, who happened to be in that province at the time, was obliged to take flight towards Spain, when he was pursued and overtaken at the foot of the Pyrenees by some emissaries of Magnentius, and killed, A.D. 350. He is represented by the historians as indolent and rapacious; Zosimus accuses him also of cruelty and other crimes, but Zosimus wrote under the influence of party feeling. The character however of all the three sons of Constantine is open to much censure. Constans protected the Christian faith, as established by the Council of Nicæa, against the Arians and Donatists, and he also shut up many heathen temples. After his death Magnentius took possession of Italy and of Rome, and styled himself Augustus, until he was overthrown by Constantius. [CONSTANTIUS.]

CONSTANT, a quantity which remains the same throughout a problem. Thus in the question, required that point of a circle which is at a given distance from a given straight line, the radius of the circle is a constant. If the problem require the use of twenty different points of the circle, the radius is the same for all.

A constant may be determinate, or it may be indeterminate or arbitrary. Thus the proportion between the circumference and diameter of a circle is a determinate constant, being 355 to 113 very nearly; but in the problem, required the relation which exists between the abscissa and ordinate of a circle, the radius of that circle is an arbitrary constant.

The term constant is frequently applied to any remarkable or very necessary number which enters a question, as follows. By the *constant* of aberration is meant that one constant by the determination of which the aberration is obtained from its known laws at any given time; in this case it is the maximum aberration, or about 20½″. [ABERRATION.] Thus we have the constant of nutation, the constant of friction, &c.

Nothing is more common in mathematical works than the term *variation of constants*, which appears a contradiction. But its meaning is as follows: a quantity which upon one supposition would remain constant, becomes variable by the introduction of another supposition. Thus, taking into account the earth's attraction only, the longitude of the moon's node is constant; but by the attraction of the sun and planets, its place is slowly changed. In this case one of the constants is said to vary.

CONSTANTIA, a farm situated about eight miles to the west of Cape Town at the Cape of Good Hope, which received its name in compliment to the wife of the Dutch governor of the colony, Vander Stel, by whom it was formed. This farm owes all its celebrity to the Constantia wine which it produces, and which is universally esteemed for its high flavour and luscious quality. The vineyard is of small dimensions, and the wine which it yields, both white and red, does not exceed from 8000 to 12,000 gallons annually, varying between these quantities according to the season. It has not hitherto been found possible to produce wine of equal quality upon any other spot within the colony

CONSTANTINE, POPE, a native of Syria, succeeded Sisinnius in 708. He visited Constantinople and Nicomedia, where he was received with great honour by the Emperor Justinian the younger. After his return to Rome he defended the worship of the images against John, patriarch of Constantinople, and against Philippicus, who had usurped the empire. Felix, archbishop of Ravenna, who had at first refused to acknowledge Constantine, and had been exiled in consequence, made his submission to him, and was reinstated in his see. Constantine died in 714, and was succeeded by Gregory II.

CONSTANTINOPLE (Stambool), literally, 'the city of Constantin,' in Roumeli or European Turkey, the capital of the Ottoman empire, is situated in 41° 0′ N. lat. and 28° 45′ of E. long., on the sea of Marmora (Propontis), and at the west end of the narrow channel of the Bosporus, which connects the sea of Marmora with the Black Sea (the Euxine). The ground on which it stands is fitted by nature for the site of a great commercial city, the connecting link between Europe and Asia. A gently-sloping promontory, secured by narrow seas, stretches out in a triangular form towards the Asiatic continent, from which its extreme point is separated by so narrow a strait (the Bosporus), that in a quarter of an hour a boat can row from one continent to the other. Indeed, Scutari, on the Asiatic coast, immediately opposite, is always considered as a suburb of the European capital. Just before the Bosphorus enters the sea of Marmora, it makes a deep elbow or inlet on the European shore, flowing between the triangle of Constantinople proper and its European suburbs of Galata and Pera, and forming the magnificent port of the Golden Horn. The triangle which, allowing for many vacant spaces within the walls, is entirely covered by Constantinople, is thus washed on one side (the northern) by the deep waters of the port, and on the other (the south-east) by the sea of Marmora. The base of the triangle, or the ground immediately beyond the walls, which attaches it to the European continent, is an open elevated flat, with some slight inequalities. The area of the triangle is occupied by gentle hills, which are highest towards the land side and the suburb of Eyoub, and gradually decline to the Seraglio point, the apex of the triangle, shelving off on each side to the sea of Marmora and the port. As Rome was built on seven hills, so the Roman founders of Constantinople called these the 'Seven Hills,' though, if the principal chain only were counted, there would be less; and if the minor hills or spaces were included, there would be more than seven. The ridge of the first hill, departing from the acute part of the triangle, is covered by the main building of the Seraglio, or vast palace of the Sultan, behind which, a little on the reverse of the hill, the dome of Santa Sophia shows itself. The second hill is crowned by the bold and lofty dome of the Osmanieh Mosque. The still loftier mosque of Solyman the Magnificent towers on the third hill; whilst an antient aqueduct, the arches of which are of a considerable span, and which is generally attributed to the Emperor Valens, unites the summits of the third and fourth hills. On a fifth point, the most elevated of the little chain within the triangle, there is a slender lofty tower, built in 1828, in which a guard is constantly kept to watch the breaking out of fires, which are very frequent and destructive in a city where all the private habitations are built almost entirely of wood. The situation of Constantinople upon hills is the main cause, not only of its picturesque beautiful appearance, but of its salubrity and comparative cleanliness. It receives all the breezes from the Bosporus, the sea of Marmora, and the adjoining plains of Thrace; and the dirt that might otherwise accumulate descends the hills' sides to the port or the open sea, in both of which it is carried off by a strong current. This natural local advantage is improved by the number of fountains and the abundance of running water which is always carrying off parts of the dirt, and by the heavy rains, which, when they fall, thoroughly cleanse the sides of the hills. The lower edge of the city that touches the port, and the suburb of Galata (the Wapping of the Turkish capital), on the opposite side of the port, may be called filthy places, but the term cannot be correctly applied to Constantinople as a whole, although from various other causes the interior of the city is far from being so beautiful and imposing as its external aspect.

The form of the triangle is somewhat irregular, the side on the sea of Marmora, from the old state prison called the Seven Towers to the Seraglio point, being considerably the longest; we have no exact admeasurement, but its length cannot be much short of five English miles. On this side the old walls and towers are in a very ruinous state, and on the side towards the port they have almost entirely disappeared. But on the land side Constantinople presents a double line of strong and lofty stone walls (the work of Theodosius II.), which might be easily put in a complete state of repair, and which, in their more dilapidated parts, present such magnificent and picturesque specimens of mural ruins as probably no other city can boast of. The length of this latter line of wall, from the head of the port to the sea of Marmora, is about four English miles. The walls are flanked at short intervals by towers, which are mostly rectangular. There are many Greek inscriptions inserted in their face; nor have the Turks been at the trouble to remove the numerous Greek crosses that are carved on the towers and over the gateways. Besides the double walls, which are almost entire, and still retain their antient battlements, the outer ditch was faced with a wall which made a third rampart, but this is in part destroyed, and seems never to have been defended by towers. Bondalmonte, a Florentine, whose plan bears the date of 1422, sets down one hundred and eighty towers, of which not more than one hundred and twenty are now standing. The intervals betweeen the walls are in many places choked up with earth and masses of the ramparts which have fallen under the shocks of war or earthquakes. The great ditch, which is about twenty-eight or thirty feet broad, is partly cultivated and converted into kitchen gardens.

There are six gates on this side:—1. Egro-Kapoussi (the Oblique Gate); 2. Edrene-Kapoussi (the Gate of Adrianople); 3. Top-Kapoussi (the Cannon Gate), through which the conqueror Mahomet II. made his public entry on the capture of Constantinople; 4. Selivri-Kapoussi (the Gate of Selivria); 5. Yeni-Kapoussi (the New Gate); 6. The Gate of the Seven Towers. The 'Golden Gate,' so celebrated by the Byzantine writers, has been sought for in vain, though a gate now wholly blocked up, with two mean pillars supporting a low arch, is sometimes shown to travellers for it. Near to the Top-Kapoussi, where Palæologus, the last of the Christian emperors, fell, is the breach through which the Turkish besiegers poured into the city: the wide rent, which has never been repaired, is now full of trees and shrubs. A waste, a stillness, and a solitude, difficult to conceive near so great a capital, reign immediately beyond these walls, which are so lofty, that from the road which passes under them the eye can scarcely catch a glimpse of the mosques and minarets of the city. This melancholy aspect is heightened by several cemeteries, with dark cypresses and white marble tombs, that lie outside of the walls.

The size of the triangle on which Constantinople stands has been greatly exaggerated. Tournefort, in general a correct observer, makes the circuit of the triangle twenty-three miles (*Voyage du Levant*, let. xii.), but the length of the three sides does not in reality much exceed thirteen miles. Gyllius (*De Topog. Const.*, l. i., ch. 4), makes the whole circuit rather less than thirteen miles, thus agreeing pretty closely with Chalcondylas, who estimates it at one hundred and eleven stadia. (*Melet. Geog.*, Art. 'Opakh.') The treble walls and ditches on the land side, the extensive gardens of the Seraglio, and other palaces, the large court yards of the royal mosques, the Hippodrome and other vacant squares, materially diminish the extent of ground covered with houses.

With the exception of the land walls, and the church of Santa Sophia, there does not remain much of the Byzantine architecture; the greater part of the antiquities which were seen by Gyllius, by Spon, and other old travellers, have disappeared. The fact is, the Turks, instead of digging in the quarry, have knocked down the Grecian buildings to use the materials in their own public edifices, such as mosques, minarets, and fountains, and to cut them up into tomb-stones.

There is a vast subterranean edifice, the roof of which is supported by an immense number of columns, each column being oddly formed of three separate pillars placed one on the top of the other. The Turks call it the palace of the 'thousand and one pillars;' not that this is the precise number, but because it is a favourite number with all eastern nations. Though the earth has in part filled it up, it is still of great depth. It was originally one of the immense cisterns or reservoirs made by the Greek emperors, and always kept full of water by them, in case of a siege, though they have long been destroyed, or suffered to go to ruin, by the improvident Mussulmans. This particular one is dry, and a number of silk-twisters have taken possession of it, and ply their trade at the bottom in almost total darkness. There is another which still exists as a cistern, though it is hardly known except to a few Turks, whose houses are situated immediately above it, and who call it the 'Subterranean Palace.' It may be described as a subterranean lake, extending under several streets, having an arched roof that covers and conceals it, supported on 336 marble pillars.

The Turks retain the translated name (they call it the At-Meidan or horse-course) of the famed Hippodrome, but all the antient splendour of the place has disappeared. It is now not a circus, but an oblong open space, about 300 paces long by 150 wide It is partly flanked on one side by the mosque of Sultan Achmet, and partly on the other by the high dead walls of a building which was once an hospital, but in 1828 a receptacle of a few wild beasts kept by the sultan. At the upper end of the Hippodrome there is a granite obelisk of rather mean proportions, and partly covered with hieroglyphics which are not of the best workmanship; it is called after Theodosius, though it is probable that emperor only removed it from another part of the city where it was erected by Constantine, and set it up here, after it had been thrown down by an earthquake. Near this obelisk is the fragment of the wreathed column of bronze, which has been the subject of many discussions. Whether it supported three serpents' heads, which Mahomet II. struck off at a blow with his battle-axe—whether it was brought from the oracular shrine of Delphi or not, we will not attempt to determine, but we can safely assert that it is now a poor mutilated thing, with one end stuck in the ground, above which it does not rise more than seven feet, with the other end open, and the hollow almost filled up with dirt and stones which the Turks have thrown into it. The marble pyramid of Constantine Porphyrogennetus, the Colossus Structilis of the old topographers, does not at present fairly stand on the At-meidan, though it is near it and visible from it: it has long been stripped of the plates of gilded bronze that once covered it; the shaft is held together by rude iron hoops, and blackened by the many conflagrations that have raged round it. It is now an unsightly object, about 90 feet in height, and 33 in circumference.

Many of the mosques erected by the Turks are distinguished by grandeur and beauty. There are fourteen chief or imperial mosques, nearly all lofty, and magnificent in their general dimensions, and built from base to dome of excellent enduring materials, chiefly of white marble, slightly tinged with grey. Some of these have two, some four, and one (that of Sultan Achmet) has even six of those light, thin, lofty, arrowy, and most graceful towers called minarets. Besides the imperial mosques, there are 60 others, varying in size and beauty, but all considerable edifices; and then 200 and more small mosques or messelgids, which are only distinguished as places of worship by having little minarets, often made of wood, contiguous to them. The mosque which has been most talked of, because it was antiently a Christian temple, and was supposed (we think erroneously) to have suggested to the Turks the grand dome or cupola which predominates in all the great mosques they built themselves, is that of Santa Sophia. Several of the imperial mosques, however, in situation, boldness, and beauty, far excel Santa Sophia, which, externally, is rendered hideous by the clumsy buttresses that have been built against it, at different periods, to keep it from falling. If the Turks really copied the dome from it, they have improved on the original, which is comparatively low and heavy, whilst most of their cupolas are lofty, light, and elegant. This is particularly the case with the mosque of the Sultan Achmet, which flanks the Hippodrome, and which may be deemed altogether the grandest edifice in Constantinople. The colleges and hospitals, which are generally attached to or near the great mosques, offer no striking architectural features; but some of the detached chapels or sepulchres (*turbés*), where sultans, viziers, and great personages repose, are handsome. The spacious barracks erected by the reigning Sultan Mahmoud for the accommodation of his *Nizam-djedid*, or troops disciplined in the European manner, may be reckoned among the public ornaments of the city and suburbs.

The public baths, of which there are said to be upwards of 120 within the walls, with their very low and small and flat domes, do not contribute to the beauty of the city externally, though within many of them are exceedingly handsome and spacious. The public fountains are remarkable and numerous: some of them, with their pure white marble facades, elaborate arabesque ornaments and Chinese roofs, are most beautiful objects. All this water, the daily consumption of which is immense, is supplied by *Bendts* or artificial lakes in or about the forest of Belgrade, at the distance of ten or twelve miles from the city: it is conveyed to Constantinople, as also to the suburbs of St. Dimitri, Pera, Galata, &c. by means of narrow subterranean aqueducts, and *souterazi*, or hollow hydraulic pyramids, which latter are placed at certain irregular distances, and so contrived as to overcome the inequalities of surface presented by the country that intervenes between the bendts and the city. Within the walls the lofty aqueduct of Valens still performs its duty, carrying the fluid across a deep hollow.

With the exception of one very long street, which traverses the city nearly from the high walls of the seraglio to the gate of Adrianople, the streets are narrow, winding, and uncommonly dull and deserted. The *gazeboo* or *shah-nishins* (projecting windows) are latticed and closed like the windows of convents; and many of the houses have no windows at all towards the street, but only a low, narrow, dingy door. All the life and activity of the interior of the city is concentrated in the bazaars or bezestines. These are long wide corridors, communicating with each other mostly in an irregular and striking manner; their side walls are built of stone, and they are covered in with stone arches or successions of domes, through which a subdued light is admitted. The dealers are separated by nations or religions and by trades. [Bazaar.] Towards the evening the coffee-houses, which are excessively numerous, though chiefly of mean appearance and dimensions, are much thronged by Turks, Armenians, Greeks, and Jews, all smoking and indulging in tiny cups of coffee, which is generally drunk by the poorer classes, not only without milk, but without sugar.

The communication between the city and the opposite suburbs of Galata, Pera, and Tophana, is kept up by means of *caïks*, or light fast wherries, the constant passing and repassing of which give the port an animated appearance in the day-time. The imperial dock-yard, the arsenal, the artillery barrack, are all on that side of the water, and the elevated plateau of Pera is the residence of the foreign ambassadors to the Porte, the drogomans, Frank merchants, &c. An active communication is also kept up by the same means with Scutari, where caravans and travellers are constantly arriving from Ismmid (Nicæa), Brusa (Prusa), Angora (Ancyra), and other places in the interior of Asia Minor

The port of the Golden Horn is safe, capacious, and beautiful; but it has one serious drawback, which affects Constantinople as a commercial emporium. During the summer, the Etesian or north wind blows unremittingly from the Black Sea down the Bosporus, the sea of Marmora, and Straits of the Dardanelles, thus retarding the approach of all sailing vessels from the Mediterranean and Ægean to the capital. Vessels undertaking the voyage upwards at that season are often detained two or even three months at Tenedos, on the coast of Troy, near the mouth of the Dardanelles, where whole fleets of wind-bound ships, laden with goods for the capital or the Black Sea, are frequently at anchor. This serious obstacle can only be overcome by steam-vessels, which are now well known and on the increase in the Sultan's dominions. The first that ever appeared in those narrow seas was a large English boat, purchased by the Turkish government in 1828. The Sultan has bought two others since then, and there are two or three belonging to companies of merchants that trade from Smyrna and the Greek Islands. In no part of the world can the usefulness of such vessels be more felt.

As a manufacturing town, Constantinople scarcely deserves mention; pipes and pipe-sticks, muslin handkerchiefs painted and embroidered, costly saddlery, and horse-trappings, are the principal articles produced. The foreign trade, however, is very considerable. In the articles of exports it is made the depôt of raw silks and opium, which are now not allowed to be shipped at any other port. It imports manufactures, colonial and other goods, not only for its own large population, but for a considerable portion of both European and Asiatic Turkey. The impoverishment of the people and the insecurity of property render nugatory many wise regulations, and prevent the growth of commerce, which might be tenfold what it actually is. The Turks have never loaded trade with heavy duties or jealous prohibitions; their code extends immunities and high consideration to merchants; but unfortunately these immunities are not enjoyed by the consumers, or by any class, and the cultivator of the soil is the helpless victim of the extortion and tyranny of the government officers. [Turkey, Commerce of.]

We have no census or official data, but the population contained within the walls of Constantinople is probably about 500,000. It is usual, in the country, to speak of 'the million of Stambool,' and to add the population of Pera, Galata, St. Dimitri, Scutari, and the numerous villages on the Bosporus; but we question whether all these would carry the number higher than 700,000 or 800,000, comprising Turks, Greeks, Armenians, Jews, and Franks.

A city stood here in remote antiquity; but if (as there are good grounds for believing) the extent of Byzantium is marked by the present walls of the Seraglio, it was a small one. [Byzantium.] The present enlarged city was founded in A.D. 328 by the Emperor Constantine, who gave it his name, enriched it with treasures of art taken from all parts of the Roman world, and soon made it the rival of Rome itself. It was taken from the degenerate Greeks in 1204 by 'the blind old Dandolo,' the Venetians, and the French, who attacked it on the side of the port. After remaining fifty-seven years in the hands of the Franks, it was retaken by the Greeks in 1261 under the Emperor Michael Palæologus. It was conquered by the Turks in 1453.

CONSTANTI'NUS, FLA'VIUS VALE'RIUS, called the Great, the son of Constantius Chlorus, was born in 274. He was brought up at the court of Diocletian, and served early with the armies in various expeditions. Being in Britain at the time of his father's death, he was proclaimed emperor by the soldiers, but he prudently referred his nomination to Galerius, who acknowledged him only as Cæsar, and governor of the provinces which had long been administered by his father. Constantine passing over into Gaul to oppose the Franks who had entered that province, defeated them as well as the Alemanni, and behaved with great inhumanity to the prisoners; he gave up their chieftains to the wild beasts as a public spectacle. (Eutropius, x.) Meanwhile Maxentius, the son of Maximianus, caused a revolt at Rome while Galerius was absent in the East, and Maximianus himself having come to Rome, resumed the title of emperor, and took Maxentius as his colleague. Severus, whom Galerius ordered to put down this insurrection, was betrayed by his troops, taken prisoner, and put to death by Maximianus. The latter however fearing the vengeance of Galerius, thought of strengthening himself by an alliance with Constantine, whom he went to meet in Gaul, and gave him his daughter Fausta in marriage. From that time Constantine was acknowledged as Emperor by the West. Soon after Maximianus having quarrelled with his son Maxentius, left Rome for Pannonia, where he met Galerius and Diocletian, who had left his retirement of Salona for the purpose of appointing Licinius a new Cæsar, in the room of Severus. There were then in the empire no less than six emperors and Cæsars, namely, Maximianus, Maxentius, Galerius, Constantine, Maximinus and Licinius. Galerius soon after acknowledged both Constantine and Maximinus, as emperors and Augusti equal to himself. Maxentius continuing to maintain himself at Rome, Maximianus visited his son-in-law Constantine, whom he attempted to dispossess of his authority by exciting his soldiers to revolt, but he was defeated and taken at Massilia by Constantine, who treated him with great indulgence, and allowed him to remain in his palace. Maximianus having next attempted to murder him in his bed, was seized and put to death. In the year 311 Galerius published an edict to stop the persecution against the Christians; this document bears the name of three emperors, Galerius, Constantine, and Licinius: Maximinus, who was in Asia, is not mentioned in it. Galerius soon after dying at Sardica in Dacia, Licinius took possession of his dominions as far as the Hellespont, and Maximinus had the whole of Asia. Maxentius continued to govern Italy, and was making warlike preparations against the other emperors, when Constantine moved with an army from Gaul to attack him, A.D. 312. He took Susa, defeated several bodies of troops sent against him by Maxentius, entered Mediolanum (Milan), and then attacked Verona, where Pompeianus, a general of Maxentius, had stationed himself. After an obstinate fight, Pompeianus was defeated and killed, and Constantine marched upon Rome, where he defeated Maxentius in person, a few miles from the capital, on the right bank of the Tiber, near the present Ponte Milvio, where Maxentius had constructed a bridge of boats. In recrossing the bridge in his flight, Maxentius was drowned, with many of the fugitives. Constantine entered Rome on the 29th of October, and was acknowledged emperor by the senate, who ordered the Triumphal Arch which still exists to be raised to him as the liberator of Rome. He is said to have behaved with moderation after his victory, having put to death only a few of the worst ministers of Maxentius, who is represented as a cruel tyrant both by Heathen and Christian historians.

It was on this occasion that Constantine adopted a new ensign for his army, which was called Labarum or Laborum; it had the figure of a cross, with the Greek letter P above it, and the Greek words ἐν τούτῳ νίκα, 'conquer in this.' Eusebius, who gives a description of it, asserts with other Christian historians, that it was assumed in consequence of a vision which Constantine had before his battle with Maxentius. Gregorius Nazianzenus says, that the name of Laborum was used as indicating that by the assistance of this new sign all 'labours' and tribulations of the empire should cease. Zosimus, Aurelius Victor, and Eutropius, say nothing of it. Much has been written on this subject. (See Gretser, *De Cruce*; and *Dissertation sur la Vision de Constantin*, par J. B. Devoisier, Bishop of Nantes.)

In the year 313, Licinius came to Rome, when both he and Constantine were named consuls, and he married Constantia, the sister of Constantine. The old emperor Diocletian died in July of that year at Salona.

A war having broken out in the East between Licinius and Maximinus, the latter was defeated, and died of poison at Tarsus: all his family were put to death by Licinius. The whole empire was now divided between Constantine, who ruled over the west, including Italy and Africa; and Licinius, who had the eastern provinces, with Egypt.

Constantine now openly favoured the Christian communion, and discountenanced and ridiculed the practices of the old religion of Rome. He exempted the Christian clergy from personal taxes and from civil duties, and granted donations and privileges to the churches. He ordered a council of the bishops of the west to assemble at Arles to settle the schism of the Donatists, and went himself to Arles; but while there he received news of the hostile intentions of Licinius, which made him march in haste at the head of an army into Illyricum. The two armies met near Sirmium in Pannonia, and again in the plains of Thrace, after which Licinius sued for and obtained peace, by giving up to Constantine Illyricum, Macedonia and Greece. On visiting these new provinces, Constantine promulgated several laws, by which he abolished the punishment of the cross, ordered that the children of destitute parents should be maintained at the public expense, and allowed the emancipation of slaves to be effected in the Christian churches in presence of the clergy without any interference of the civil magistrate. By another law, promulgated at Sardica in December, 316, he gave to the vicars or governors of the provinces full power to try persons of every rank accused of oppressions and robbery, without any appeal to Rome, by which he put a check on the overbearing insolence of the rich towards the poor. In the year 318, Crispus, son of Constantine by his first wife, obtained the consulship with the younger Licinius, the son of Licinius. Constantine spent several years in visiting the provinces of the empire, and promulgating new laws, which were conceived for the most part in a humane and liberal spirit: he abolished the punishment of flagellation formerly inflicted on defaulters in the payment of taxes, introduced a better discipline into the prisons, repealed the old laws against celibacy, and forbade concubinage, which was then allowed by the Roman laws. He also prohibited nocturnal assemblies, and certain obscene rites of Paganism; but he did not attempt to forbid the exercise of the old religion.

By an edict of March, 321, he ordered the observance of the Sunday, and abstinence from work on that day. In the year 322 he defeated the Sarmatians and the Getæ or Goths, and repulsed them beyond the Danube. On returning to Thessalonica, where he was constructing a harbour, the Goths appeared again, and invaded Mæsia and Thrace. Constantine again attacked them, and pursued them into the territories of Licinius. This was made the pretence of a new war between the two emperors, in which Licinius being defeated near Chalcedon, by sea and by land, escaped to Nicomedia, and there surrendered to Constantine, who, at the intercession of his sister Constantia, promised him his life, and sent him to Thessalonica, where however he was soon after put to death, A. D. 324. Licinius has been spoken very unfavourably of by most historians. Constantine, being now master of the whole empire, extended to the east his laws in favor of the Christian religion. He forbade consulting the haruspices and the oracles, ordered the churches of the Christians which had been demolished under Maximinus and Licinius to be rebuilt, and the property of the church to be restored, and more especially the burial grounds of the Martyrs; and reinstated in their rank and right all those who had been prosecuted or exiled for religion's sake. In writing to the Metropolitans he styled them 'well-beloved brethren.' He published a Latin edict, which was turned into Greek by Eusebius, addressed to all the subjects of the empire, in which he exhorted them to renounce their old superstitions, and to adore only one God, the Saviour of the Christians. In 325 he assembled the first universal council of Nicæa, which he attended in person. [ARIUS.] On the 25th July of that year, being the anniversary of his accession to the empire, he gave a great entertainment to all the fathers of the council, to whom he gave considerable gifts and sums to distribute to the poor. From Nicomedia, where he resided for some time, he issued an edict inviting all the subjects of the empire to address their complaints to him in person against any abuse of authority of the governors and magistrates. By another edict he abolished the fights of gladiators, and ordered that the convicts, who were formerly compelled to fight against them or against the wild beasts, should be employed in working the mines. These facts show a great alteration in Constantine's mind from the time when he himself gave up the Frankish prisoners to the wild beasts in the amphitheatre.

In the year 326 he repaired to Milan, and then to Rome, being consul, for the seventh time, with his son Constantius; he remained at Rome but a short time, and left it in disgust, never to return to it. According to Zosimus and Libanius the Romans were dissatisfied with him for having forsaken the old religion, and expressed their discontent by biting satires. By the end of the year we find Constantine at Sirmium, in Pannonia. In this same year is recorded the tragical death of Crispus, the eldest son of Constantine former wife or concubine, a young man who had be by Lactantius, who has been praised by Eu had given proof of his courage and ab He was falsely accused by his st endeavoured to seduce her, a sovereign power, and upon either of these charges his father had him beheaded: at the same time he put to death young Licinius, his sister's son, the motive for which is not ascertained. But it was soon after discovered, some say through Helena, the mother of Constantine, that the young prince was innocent, and that Fausta herself had been repeatedly guilty of adultery, upon which she also was put to death with several of her accomplices. Constantine's suspicious temper added to the number of the victims.

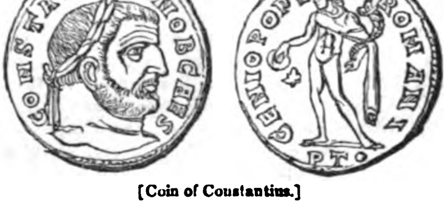
About the year 328 Constantine began to build his new capital, which was called by his name, and the spot was judiciously chosen. It was a Christian city, chiefly inhabited by Christians, and no Heathen temples were built in it. In May, 330, the new town was solemnly dedicated to the Virgin Mary. Meantime the emperor was repeatedly engaged against the Goths and other barbarians on the banks of the Danube. In the year 328 he recalled several Arian bishops, Eusebius of Nicomedia among others, who had been exiled by the council of Nicæa. This change is said to have happened at the suggestion of Constantia, who was herself in the Arian communion, and retained to the last much influence over her brother Constantine. Athanasius having opposed the re-admission of the Arians into the church communion, this led to a long controversy between him and the emperor, which lasted till the death of the latter. [ATHANASIUS.] Constantine was fond of religious polemics, and himself wrote on the Arian and Donatist controversy. The remaining years of Constantine's life were chiefly spent in embellishing his new capital and attracting inhabitants, especially Christians, to it; the rich by privileges, the working men by daily distributions of corn and oil. He made a division of the empire, to take effect after his death, among his three sons, whom he had named Cæsars, giving to Constantine, the eldest, the Gauls, Spain, and Britain; to Constans, Illyricum, Italy, and Africa; and the east to Constantius. To Dalmatius, one of his nephews, he gave Macedonia and Achaia, and the other, Annibalienus, he made king of Pontus and Cappadocia. He likewise divided the authority of the præfect of the prætorium among four præfects, of the East, of Macedonia and Dacia, of the Gauls, and of Italy. These four great governments were subdivided into provinces, administered by vicars or propræfects. He took away from the præfects all military power, constituting them merely as civil and political officers. He is charged by Zosimus, who is strongly biassed against Constantine, with having effected another change which proved fatal to the empire, namely, the removal of the military stations on the frontiers, and the placing of the soldiers in garrison in the towns of the interior; but perhaps this was only on some particular points, where the barbarians had encroached and were likely to cut off the old border stations. We find that he gave lands in Thrace and other provinces south of the Danube to the Sarmatians, who had been driven from their country by the Goths. Constantine probably thought of making one race of barbarians a rampart to the empire against the other. In the year 337, when preparing to march against the Persians, who had commenced hostilities, he fell ill at Nicomedia, and died, in his sixty-fourth year. He is said to have received baptism on his death-bed from an Arian bishop; for although long converted to Christianity he was still only a catechumen, as was frequently the case with converts in that age. His body was transferred to Constantinople, where it was buried, after a sumptuous funeral. The senate of Rome placed him among the gods, and the Christians of the East reckoned him among the saints: his festival is still celebrated by the Greek, Coptic, and Russian churches, on the 21st of May.

The character of Constantine has been the object of various and contradictory judgments, according to the religious and political spirit of the various writers. Eusebius, Nazarius, and other Christian contemporaries, grateful for the protection afforded by the emperor to the Christian religion, may be considered his panegyrists, while Zosimus and other Heathen writers, animated by an opposite feeling, were his enemies. The brief summing up of Eutropius is perhaps nearest the truth. 'In the first part of his reign he was equal to the best princes, in the latter to middling ones. He had many great qualities; he was fond of military glory, and was successful. He was also favourable to civil arts and liberal studies; fond of being loved and praised, and liberal to most of his friends. He made many laws; some good and equitable, others superfluous, and some harsh and severe.' He has been blamed for dividing the empire, but that had been done already by Diocletian; in fact it was too large and straggling to remain in the possession of a single dynasty. By founding another capital in the east he probably did not accelerate the fall of the west, while at the same time he established a second empire, which lasted for more than a thousand years after his death. (Eusebius, *Life of Constantine*; Zosimus; Aurelius Victor; Eutropius, and other numerous writers, a list of whom is given by J. Vogt; *Historia Litteraria Constantini Magni*, 1720.)

[Coin of Constantine the Great.]

British Museum. Actual size. Gold. Weight, 70 grains.

CONSTANTIUS I., called CHLORUS, on account of his habitual paleness, son of Eutropius, of a distinguished Illyrian family, and of Claudia, niece of the Emperor Claudius II., was born about A.D. 250. He served with distinction under Aurelian, Probus, and Diocletian. In the year 291, Maximianus, the colleague of Diocletian, named him Cæsar and his colleague, while Diocletian chose on his side Galerius: the administration of the empire was divided among the four. Constantius had for his share the Gauls, Spain, and Britain. Both the new Cæsars were obliged to repudiate their wives. Constantius, whose first wife was Helena, the mother of Constantine, married Theodora, daughter of Maximianus; Galerius married Valeria, daughter of Diocletian. Constantius carried on war against the Franks, who began to be troublesome on the Lower Rhine, and took a vast number of them prisoners. He restored the town of Augustodunum (Autun), which had been devastated by Tetricus, one of the thirty tyrants. He then repaired to Britain, with Asclepiodotus, one of his lieutenants, who defeated Allectus (A.D. 300) the successor of Carausius in the usurped dominion of the island. Britain was thus restored to the empire after a revolt of ten years. On his return to Gaul, Constantius went against the Alemanni, whom he defeated with great slaughter near Vindonissa in Helvetia, some say near Langres, and drove them beyond the Rhine. About this time he founded the town of Constantia (Constanz). In the year 304 the two emperors, with the two Cæsars, came to Rome, where they enjoyed the honour of a triumph. In the following year Diocletian and Maximianus abdicated, and appointed Constantius and Galerius their successors, who in their turn appointed two new Cæsars as their colleagues, namely Severus and Maximinus Daia, or Daza. Constantius continued to administer his old government of Gaul, Spain, and Britain. His administration, which was equitable and humane, is greatly praised by the historians, both Christian and heathen. He put a stop to the persecutions against the Christians, and employed many of them about his person. The last campaign of Constantius was against the Caledonians, some say against the Picts, whom he defeated. He died soon after at Eboracum (York) in the arms of his son Constantine, whom he appointed his successor A.D. 306. By his second wife Theodora, Constantius left several children, Dalmatius, Julius Constantius, who was the father of Constantius Gallus and of Julian the Apostate, and Constantia, afterwards married to Licinius.



[Coin of Constantius.]

British Museum. Actual size. Copper, silvered. Weight 116 grains

CONSTANTIUS II., FLAVIUS JULIUS, son of Constantine the Great, was left, by his father's will, emperor of the east. The troops, however, in order to secure the empire to the three sons of Constantine, killed Julius Constantius, half-brother of the late emperor, Dalmatius and Annibalienus, his nephews, and other of his relatives, with several patricians and ministers. This massacre was allowed by Constantius, and some say was ordered by him; only two nephews of Constantine escaped, Gallus and Julianus, afterwards emperor. Constantius was repeatedly engaged in war against the Persians and the Armenians, but with little success on his part. Ammianus Marcellinus, in speaking of these wars, says that the Romans were successful when led by the emperor's lieutenants, but were generally losers when led by the emperor in person. After the death of Constans, A.D. 350, Constantius marched with a large force against Magnentius to revenge his brother's death, and at the same time to take possession of his dominions. A desperate battle was fought, A.D. 351, near Mursa, on the banks of the Drave, and at last the cavalry of Constantius gained the victory. Magnentius escaped into Italy, but Constantius was too much weakened by his victory to follow him until the next year, when he entered Italy, defeated Magnentius again, and obliged him to escape into Gaul. In the year after, 353, Constantius again defeated Magnentius in Gaul. The usurper, finding himself forsaken by his soldiers, killed himself, and his brother Decentius, whom he had made Cæsar, followed his example. Constantius now became master of the west as well as of the east, and thus reunited the whole empire under his dominion. He had appointed his cousin Gallus Cæsar and governor of the east, when he set out to oppose Magnentius. In the same year, 353, Constantius assembled a council at Arles, which was composed of Arian bishops. The emperor favoured that sect, and persecuted the orthodox or Nicæans, and exiled many of their bishops, among others Liberius, bishop of Rome. In the year 354, Constantius, having received repeated complaints of the cruelties and oppressions committed by Gallus in the east, sent for him and caused him to be beheaded in Dalmatia. Several conspiracies were also discovered or invented by the courtiers of Constantius, and numerous persons tortured and put to death. Meantime the Franks and the Alemanni had passed the Rhine, and destroyed Colonia (Cologne) and other towns; the Quadi and the Sarmatians were ravaging Pannonia, and the Persians attacked the eastern provinces. It was in this emergency that Constantius, being at Milan in November, 355, proclaimed his cousin Julian Cæsar, gave him his sister Helena in marriage, and sent him as commander to the Gauls. In the following year Constantius issued laws forbidding under pain of death any sacrifice to idols, and condemning to death all magicians, astrologers, and soothsayers. In 357 the emperor repaired to Rome for the first time, and was received with great pomp by the senate, and public festivals and games were celebrated in his honour. He caused the obelisk which Constantine had removed from Heliopolis to Alexandria, to be carried to Rome, where it was raised in the Circus Maximus: it was now called the Lateran Obelisk. Constantius having returned to the east, defeated the Sarmatians, while Julian conquered the Germans on the Rhine. He then marched against the Persians, but was unsuccessful. In the mean time Julian had been proclaimed emperor by the soldiers at Paris. Constantius was making preparations to attack him, when he was taken ill at Tarsus, and died, A.D. 361. On his death-bed he named Julian his successor. Constantius, though not a good prince, had yet some valuable qualities. He was cautious and discriminating in the appointment of his great officers; he took care of the soldiers; he bestowed office generally on the most deserving; was fond of science and application, was temperate, sober, slept little, and his habits were regular. But he was suspicious, and cruel in consequence of his suspicions. He oppressed the people with taxes, and spent much money in pomp, parade, and useless building. (Ammianus, b. xiv.)

CONSTANZ, also Costnitz, the capital of the Baden Circle of the Lake, is on the left or southern bank of that part of the lake of this name, where the Rhine begins to form the Untersee; in 47° 36′ N. lat., and 9° 10′ E. long. It is fortified in the old style, with a high wall flanked by towers and a broad ditch, besides bastions on the western side and the side of the lake. Kreuzlingen, one of its suburbs, separated from it by a ditch, is defended by two bastions; and Petershausen, which lies on the other side of the strait that connects the Bodensee and Untersee, is united to Constanz by a covered wooden bridge, on which there are grinding and sawing mills. In this last suburb is the castle of Petershausen, a fortress the works of which have been converted into pleasure grounds. There is a third suburb, called Paradise, in which Huss the reformer, and Jerome of Prague, his brother-reformer, were burnt, and which may now be termed the nursery grounds and orchard of Constanz. The most remarkable buildings in the town are the cathedral, which contains a magnificent high altar, some fine mosaic pavements, &c., and the church of St. Stephen; the antient Minorite or Dominican monastery, now a cotton factory, with the tower in which John Huss was confined; the Kaufhaus or mart, once a Carthusian monastery, built in 1388, which contains the hall where the council sat (1414-18), which deposed three popes, and condemned Huss and Jerome of Prague to the stake; the old Dominican monastery on the island of Genf, in which are the tomb and epitaph of Emanuel Chrysoloras, who died here in 1415, &c. Constanz is the seat of various official departments, and has a lyceum, gymnasium, hospital, and Dominican nunnery for the education of young females. It contains about 930 houses and 5600 inhabitants, a sad decrease since the fifteenth and sixteenth centuries, when the population was from 25,000 to 30,000. Indeed it is now a lonely deserted place, and the grass is growing in the streets. The chief occupations are trade, fisheries and navigation, the cultivation of vineyards and gardens, brewing, and some few manufactures. Constanz is one of the oldest towns in Germany, and previously to the fourth century bore the name of Gannodorum. [CONSTANTIUS I.] It was formerly a free imperial town, but fell under the ban of the empire in 1548, and in 1549 was annexed to Austria, which ceded it to Baden in 1810.

CONSTANZ, or CONSTANCE, a large lake, called also the Bodensee (from the antient castle of Bodmann) or the lake of Costnitz, forms part of the south-west boundary of Germany on the Swiss side, and is the common property of the several states on its banks, namely, Austria, Bavaria, Würtemberg, Baden, and Switzerland. It lies between 47° 28′ and 47° 48′ N. lat., and 9° 2′ and 9° 44′ E. long. It is 1283 feet above the level of the sea: its greatest length, from Bregenz to Bodmann, is about forty-five miles; its greatest breadth, between Rorshach and Friedrichshafen, is about thirteen miles, and its average depth is 320 feet, the greatest being 964. The entire lake occupies an area (exclusive of the islands) of about 199 square miles, of which about twenty-two belong to the Zellersee. It is divided into the Upper and Lower Lakes, of which the Upper, which is by far the most considerable, extends from Bregenz to Constanz. The Lower Lake is subdivided into Lake Zell or Zellersee, which is about sixty feet deep, contains the fertile island of Reichenau, belonging to Baden, and into what is properly called the Lower Lake (Untersee), through which the Rhine flows. The northernmost bight, which contains the island of Meinau, also belonging to Baden, and the island of Lindau, is called Lake Bodmer, or the Ueberlingersee. The Rhine enters the lake at Rheineck, and leaves it at Stein. Above fifty larger and smaller streams, such as the Bregenz, Schuszach, &c., empty themselves into Lake Constanz. It was frozen over in 1477, 1572, 1695, and 1830. It has on several occasions been subject to sudden risings of the waters. In 1549, according to Dr. Stein, it rose four or five times in one hour to the height of an ell, or upwards of two feet above its ordinary level; in 1770 it rose in one hour from twenty to twenty-four feet above the ordinary level. There is a considerable traffic on the lake in corn, timber, cattle, wine, fruit, &c., but it is rather dangerous, from being subject to sudden squalls; the navigation is besides impeded by the fall of the Rhine at Schaffhausen. It contains seventy-three kinds of aquatic and marsh fowl, twenty of shell-fish, and twenty-six of fish, particularly salmon-trout, pikes, carp, and salmon; the latter however is not the true salmon, but the *Salmo murena*. The wine, called lake-wine, grown along the lake, is rough, but becomes excellent when old. The Lake of Constanz and its environs present the most varied and picturesque scenery in Germany. It is mentioned by antient writers under the name of Lacus Brigantinus; Pliny expressly assigns it to Rhætia; others reckon it part of Vindilicia. It bore other names, such as Rheni Lacus, Suevicus L., in addition to Brigantinus L., from the Brigantii who dwelt on its banks. Tiberius built a fleet on it in order to attack the Vindilici. (Strabo, vii. 292.)

CONSTELLATION (a putting together of stars), the name of one of those groups of stars into which the whole heavens are divided, and to each of which is imagined to belong the figure of a man, an animal, or some other object, natural or artificial.

The history of the constellations is a matter of mythological antiquity, the most curious features of which are connected with the twelve signs or constellations of the ZODIAC, or the sun's apparent yearly track. It is sufficient for us here to say, that it is certain we derive our constellations for the most part from the Greeks, and that it is nearly as certain that they derived them from the East, though it is highly probable that they altered the legends to suit their own mythology, and in some instances even the figures. Their firmament, if it confined itself to recording the vast and striking events of their mythic system, as in Argo or Hercules, might bear an external presumption of originality, which it wants altogether while so prominent a constellation as the Great Bear represents nothing but the unimportant and irrelevant story of Callisto. But while we are just in possession of sufficient knowledge to deny the original formation of the constellations to the Greeks, and perhaps even to the Egyptians, we have not enough to say in what nation they were first constructed.

The method of figuring the constellations, though in many instances it gives groups which are striking to the naked eye, is one of the worst which could have been invented for the modern purposes of astronomy. A dragon winding round three-quarters of the globe, and a man extending his arms and legs between half a dozen other figures, cannot connect their included stars in any manner which will lead to useful combinations. So that in our modern catalogues, though λ Draconis and *z* Draconis are said to be in the same constellation, the connection is purely one of names, and suggests no ideas of relative position. There are even instances in which stars bearing the name of one constellation are situated in another.

We shall proceed to describe the methods by which the stars in a constellation are distinguished, and the plan we have adopted in the present work. The letters of Bayer are generally adopted for all the stars in his maps. The stars were ranged by him in order of brilliancy, as they appeared to the naked eye about A.D. 1600. The Greek letters were first used, and afterwards the Italic small letters. Thus α is the most brilliant star in a constellation according to Bayer, while *p*, *q*, &c. are comparatively faint. Other astronomers have since carried on the lettering of Bayer, and we have latterly (in this work) distinguished the letters added since Bayer's time by parentheses in all those constellations which were partly lettered by Bayer and partly by others. But in all cases the extent of Bayer's letters may be ascertained by reference to the article headed by his name. The letters had been adopted, however, previously to Bayer. [PICCOLOMINI.]

The next step in the arrangement was that of Flamsteed, who retained the old method of describing stars by their situation in the figure of the constellation (as in the leg, in the head, &c.), but placed the stars of each constellation in order of right ascension, or in the order in which they come on the meridian. Succeeding astronomers described each star by the number which it stood from the beginning in the constellation, and called it Flamsteed's number. Thus 7 Draconis means that star of Draco which comes on the meridian the seventh of all the stars observed by Flamsteed in that constellation. Mr. Baily, in his new edition of the British Catalogue, has introduced new stars from Flamsteed's papers, but has allowed them to stand without disturbing the established numbering, and they are easily identified by the general numbering of the new catalogue. Thus, there is a star in Capricornus between 12 Capr. and 13 Capr., which may be described as 2786 of Mr. Baily's edition, that is, the 2786th from the equinox of 1690 of *all* the stars observed by Flamsteed, both of those which are in the British Catalogue of A.D. 1725 and those which have been since drawn from Flamsteed's papers.

The numbering of Piazzi is on a different and inferior principle. The whole heavens being divided into twenty-four hours of right ascension, the stars are numbered in their respective hours of right ascension. For instance, (303) Can. Maj. is, according to Piazzi, a star in Canis Major, not the 303rd of that constellation, but the 303rd of the hour of right ascension in which it fell in the year 1800, counting the first star of the catalogue which passed after the sidereal clock had marked the hour as 1, the second star as 2, &c., and affixing to each the name of the constellation in which it is. If the equinox were fixed, this method would be a good first correction of the vagaries of the constellations; but as it is, some stars which were in one hour of right ascension when Piazzi formed his catalogue are now in another, such as 12 Cancri, 15 Argus, &c., which were in 1830 on the borders of the 7-8 hour of right ascension.

In most other catalogues, such as those of Bradley, Lacaille, Mayer, Fallows, &c., the stars are usually numbered in their order from the beginning of the catalogue, the order being that of right ascension.

The Astronomical Society's Catalogue (published in 1827) is the basis of the enumeration of stars contained in this work. It professes to be a reduction to the year 1830 of all the stars of the following description which were observed by Flamsteed, Bradley, Lacaille, Mayer, Piazzi, and Zach; to which a few of Fallows' additions to Lacaille are joined. The whole list contains—

1. All the stars to the *fifth* magnitude inclusive, wheresoever situated.
2. All the stars to the *sixth* magnitude inclusive, situated within 30° of the equator.
3. All the stars to the *seventh* magnitude inclusive, situated within 10° of the ecliptic.

Bayer's letters and Flamsteed's numbers are both given where they exist. Where these are not found, *Piazzi's* numbers are given in *parentheses*, ( ), and where these are not found, *Bradley's* numbers in *brackets*, [ ]. Failing all these, we see Zach's numbers (with Z annexed) or Lacaille's (with C), or Fallow's (with Fa.) All Mayer's stars (some excepted, which have not been found again) are in Piazzi. The number in the catalogue itself (reckoning from the beginning) is in a separate column. The magnitudes are from Mr. Baily's Flamsteed so far as they go, and where that fails, from the catalogue.

The recognised makers of constellations are Aratus, Ptolemy, Bayer, Hevelius, and Lacaille. But Tycho Brahé, Lemonnier, and Poczobut have each added one constellation in the following list, and Halley two. The names without any letter are all in Aratus. (Remember, however, that Libra is only the *claws* of the Scorpion, both in Aratus and Ptolemy.) [LIBRA.] Three additional ones in Ptolemy's Catalogue are denoted by P.; Bayer's by B.; Hevelius's by H.; Lacaille's by L.; Tycho Brahé's by T.; Halley's by Ha.; Lemonnier's by Le.; and Poczobut's by Po.

There are many other constellations formed by different individuals; but these are not now generally admitted. Such are the Antinous of Tycho Brahé; the Mons Mænalus and Cerberus of Hevelius; the Oak of Charles II. and the Cor Caroli of Halley; the Table Mountain and the Nubecula Major and Minor of Lacaille (the latter being not clusters of distinct stars, but large nebulæ); the Reindeer of Lemonnier; the Reaper of Lalande; the Honours of Frederic, the Sceptre of Brandenburgh, Herschel's Telescope, the Balloon, the Mural Quadrant, the Cat, and the Log Line of Bode; and George's Harp of Hell. Many others, we believe, have been proposed, but there would be little use in reviving their names. In fact, half a century ago, no astronomer seemed comfortable in his position till he had ornamented some little cluster of stars of his own picking with a name of his own making.

---

* The Avis Indica of Bayer. [Correct *Apis* Indica in BAYER.]

† Crater is a separate constellation in Ptolemy. The neighbouring stars on the body of Hydra were considered by Flamsteed as part of this constellation.

‡ This is the Apis of Bayer, called Musca by Lacaille: there is however a constellation Musca, formed by Bode, we believe, and situated close to Aries, the stars of which are usually considered as belonging to Aries.

§ A part of Aquila in Aratus.

‖ Only one in Aratus and Ptolemy. Another added by Hevelius.

In the large maps of the stars, published by the Society for the Diffusion of Useful Knowledge, the constellations are figured precisely as described by Ptolemy, and the additional ones are not drawn, which will therefore render them useful to the readers of Greek astronomical works.

CONSTIPATION, an undue retention or an imperfect evacuation of the fæces. The alimentary canal, considered physiologically, may be divided into two portions; one appropriated to the conversion of the aliment into nutriment, and the other appropriated, among other functions, to the separation and discharge of the refuse matter of the aliment. The first constitutes the apparatus of digestion, and the second that of fæcation. Independently of the organs appropriated to the performance of the preparatory operations of prehension, mastication, insalivation, and deglutition, the apparatus proper to digestion consists of the stomach, the duodenum or the second stomach, the jejunum, and the ileum, the three latter portions of the alimentary canal forming the small intestines. It is in these great digestive chambers that the processes of chymification and chylification are performed; processes by which the multifarious substances taken as food are converted into an homogeneous substance analogous in its composition to the blood. The requisite changes on the food are effected partly by secretions formed by the walls of the digestive chambers themselves, and partly by secretions elaborated by distinct organs and conveyed into the digestive chambers by separate tubes. These auxiliary organs are the pancreas and the liver, the fluids secreted by which perform a most important part in the function of digestion. The chyle, the ultimate result of the action of these digestive fluids, is absorbed, as it is formed, by a set of vessels termed the lacteals, spread out upon the walls more especially of the jejunum and ileum, upon the surface of which they take their origin by open mouths.

But a considerable portion of the substances taken as food is incapable of being converted into chyle: this is separated from the chyle partly in the duodenum, and still more perfectly in the jejunum and ileum, as it flows over the walls of these extended chambers. Moreover, a considerable portion of the digestive fluids themselves does not enter into the composition of the chyle, but is separated from it and mixed with the refuse matter of the food. Again, the whole extent of the alimentary canal, from its commencement to its termination, is lined with a membrane which secretes a peculiar fluid, termed mucus. This fluid, which defends the delicate and sensitive vessels that are crowded on every point of the digestive chambers, and which maintains those chambers in a state of suppleness and moisture, is constantly formed, removed, and renewed. That portion of it which has served its office, and which has become effete, is mixed with the refuse matter of the aliment and of the digestive fluids. All these substances mixed together in a common mass are transmitted to the second portion of the alimentary canal, which consists of the large intestines; namely, the cæcum, the colon, and the rectum, by the operation of which the second part of the digestive function, that termed fæcation, is performed. This function consists of two processes; first, of that by which the common mass of excrementitious substances is brought into a state fit for its discharge from the body; and secondly, of that by which a force is generated adequate to effect its discharge. The chief agent by which these substances are brought into a state fit for their discharge is the bile. [Bile.] The agent by which their actual discharge is effected is the muscular coat of the intestines, which is excited to contraction, and thereby to the generation of the force requisite to the accomplishment of the object, by the stimulus of the bile.

It is obvious, then, that the matters to be discharged from the alimentary canal do not consist, as is vulgarly [illegible]posed, merely of the refuse portion of the food; this [illegible]itutes only a small part of those matters; an essential part of it consists of the refuse matter of secretions which have performed most important offices in the economy.

There is manifest in the performance of certain functions of the body a tendency to periodicity. The most remarkable of these are the return, at regular periods, of the necessity for sleep, of the appetite for food, and of the command to remove from the body the excrementitious matters prepared in the alimentary canal. Whatever may have first led to the formation of these habits, and however they may be varied by circumstances which operate at an early period of life, they cannot, after having been once formed, be materially and frequently interrupted, without danger to the health. The interruption of one of these habits by the retention of the fæces beyond a determinate period, namely, the period of twenty-four hours, constitutes the disease termed constipation, a disease often disregarded, generally considered of little importance, always productive of mischief, and very frequently terminating in a fatal result.

The slighter degrees of constipation, when, as is sometimes the case, they are attended with no appreciable disturbance of any function, can scarcely be considered as morbid; but, in general, a retention of the fæces beyond the period of twenty-four hours, is attended with manifest disorder. This disorder is commonly increased in proportion as the retention is protracted beyond that determinate period, and in proportion to the frequency with which such retention recurs. The amount of the disorder thus induced is however a good deal influenced by constitutional peculiarity; for there are individuals whose fæcal evacuations are not more frequent than once a week, or once a fortnight, or even once in three weeks. Such an habitual retention of the fæces, in the few cases in which it occurs, generally happens in females who lead a sedentary life, and who take little food and less exercise.

It may be sometimes difficult to connect any distinct disorder with this torpid action of the apparatus of fæcation; yet the health of the persons in whom it occurs is seldom sound, and never robust. Even in the still more extraordinary cases of constipation (and the details of many such cases are recorded in the annals of medicine), in which persons have gone five, six, seven weeks, and even, as is stated, as many months without a single fæcal evacuation, no manifest, at least no decided, injury to the health appeared to result for some time; but sooner or later, in almost every case, the enormously distended intestines became suddenly inflamed, and death followed with great rapidity. Two remarkable instances of this are on record, which it may be instructive to relate. A young female who never had more than one evacuation every two months during a period of five years, and who enjoyed good health during all that time, at length went on for the space of seven months without passing a single fæcal evacuation. Notwithstanding this extraordinary retention of the fæces, her health did not appear materially to suffer, until at last inflammation suddenly came on, which rapidly terminated life. Mr. G——, a medical officer in the French service, had always been costive from birth. He ate largely, but seldom passed a stool oftener than once in one or two months, and his abdomen assumed a large size. At the age of 42 his constipation was unusually prolonged to three or four months. In 1806, after medicines had been taken to procure a stool, which had not been passed for upwards of four months, abundant evacuations continued for nine days, and contained the stones of raisins taken a twelvemonth before; but the constipation returned. In 1809 the enlarged abdomen became painful, vomiting supervened, and he died at the age of 54, having seldom through life passed more than four, five, or six stools in the year.

These are the extreme cases of constipation; and they show the ordinary result that takes place when the unnatural distension of the intestine is brought on in the most gradual manner, and when the organ seems to be habitually accustomed to it; that is, when its extreme torpor seems to be, in the strictest sense in which such a term can be employed, constitutional. Of course when such a state of torpor comes on, in a system not habituated to it from an early period of life, the danger is increased a hundred-fold.

The immediate effects of constipation, when this disease occurs in its usual degree, in ordinary habits, is the production of some one or more of those painful states, the signs of which are generally grouped together under the common name of dyspepsia. There is disordered appetite, which is either deficient, capricious, or voracious; a dry, coated, or clammy tongue; thirst, or some disagreeable taste in the mouth; dulness, heaviness, confusion, giddiness, or pain in the head; physical and mental torpor; dry and hot skin; and last, though not least, an irritable temper, and a capricious or a desponding mind.

The remote effects of constipation are far more numerous and serious than is commonly understood. It is impossible to enter into a full detail of them in this place. But among the most obvious may be mentioned, the origin of various diseases of the skin. Between the internal covering of the body, a principal part of which consists of the membrane which lines the inner surface of the alimentary canal, and the external covering of the body, or the skin, as there is a close relation in structure, so there is a most intimate sympathy. Pimples, blotches, eruptions, unsightly and painful, of various forms and names, have their origin in an irritation excited and maintained in the alimentary canal by fæcal retention. When the fæcal matters are retained beyond a certain period they undergo chemical changes, by which their nature, originally irritating and noxious, becomes far more acrid than in a healthy state, and in extreme cases almost poisonous to the system. There is abundant evidence that these acrid and poisonous matters are absorbed from the surface of the intestines, and carried into the blood, which they corrupt, and to which they give irritating properties. The taint thus communicated to the blood is manifest in the vitiated nature of all the excretions eliminated from it and expelled from the body, and in the corrupted condition of many of the secretions formed from it, and retained in the system; but more especially in the exhalation from the lungs and bronchi, constituting a fetid breath, and in the perspiration from the skin, forming a fetid atmosphere around the body. It is observed by Dr. Copland, that in almost every instance in which the fæces are retained four, six, eight, or ten days, the breath is loaded with an offensive vapour, or the perspiration is abundant and disagreeable, or the urine is copious and unusually loaded; and that it is thus manifest that the disorder is connected with a rapid absorption from the alimentary canal, and with an augmented evacuation by the other excretory surfaces and organs. Now, as one of the principal emunctories by which the blood endeavours to get rid of the acrid matter with which it is loaded is the skin, so the skin is one of the first organs to suffer from the irritating matter brought to it to be discharged. Hence the dirty, dull, doughy, dusky, sallow colour of the skin, giving rise to a more than sufficient variety of bad complexions, so strikingly in contrast with the fresh and bright and glowing colour of the skin where pure blood, in natural quantity and with natural velocity, circulates through it. Hence the irritating and painful eruptions which constitute a large portion of the long catalogue of cutaneous diseases that disfigure the body; and hence the numerous, and even dangerous, cutaneous diseases to which children especially are subject, in consequence of the irritation excited in their acutely sensible alimentary canal, by improper articles of diet, taken in improper quantities.

Moreover, headache and giddiness existing as severe and permanent affections, and the distinct diseases called colic [Colic], chorea [Chorea], epilepsy, chlorosis, hysteria, hæmorrhoids, and many others, have their most frequent origin in an habitual and protracted retention of the fæces.

The usual termination of constipation when severe, frequent, and obstinate, is, as has been stated, in inflammation of the intestines, which commonly assumes the form either of ilius [Ilius] or enteritis [Enteritis], and which rapidly proves fatal.

There is, without doubt, a greater tendency to constipation in some temperaments than in others; in the melancholic, for example, than in the sanguineous, and in certain individnal peculiarities of constitution. But this tendency would appear to be capable of being superinduced by the habitual use of certain kinds of indigestible food; such as imperfectly fermented bread, heavy pastry, as dumplings, &c.; indigestible vegetables, as cucumbers, melons, &c. The tendency thus superinduced may be greatly increased by the use of astringent and stimulating beverages, sedentary habits, long indulgence in sleep, &c. The immediate causes of constipation are, 1. an impaired or torpid action f the liver, in consequence of which there is either a deficient or a vitiated secretion of bile. It has been stated that one portion of the bile [Bile] mixes as an essential constituent with the chyle, by which the nutritive part of the food is assimilated to the constitution of the blood; the other portion of the bile consists of excrementitious matter, principally of a resinous nature. It is this resinous portion of the bile that constitutes the proper stimulus to the colon and rectum, whose office it is, by the contraction of the fibres which form their muscular coat, to remove the fæcal matters from the body. A certain change in the quantity or quality of the bile must therefore necessarily diminish the action of these organs, by depriving them of the stimulus on which their action mainly depends. 2. Torpor of the muscular coat of the alimentary canal itself, and more especially of that portion of it which constitutes the large intestines. 3. The production and accumulation of flatus in these organs, by which their thin parieties are distended, and even a mechanical obstacle is afforded to the passage of the fæces.

The treatment of constipation should always have in view two objects:—1. the immediate removal of the impacted fæces; and 2. the change of the pathological condition of the system in general, or of the alimentary canal in particular, on which the fæcal retention depends.

The choice of the particular remedies adopted for the immediate removal of the retained fæces is often a matter of the last importance. The coats of the intestines are already in a state of preternatual distension; they have lost in a great degree their vital power; they have a peculiar tendency to lapse, from the operation of slight causes, into the state of inflammation. All purgative medicines are irritants, and the most active are powerful irritants. If the purgative employed be of a highly acrid nature, it may excite inflammation in the intestines, by the very stimulus by which it removes the retention of the fæces; but if it irritate the intestines, without overcoming the obstruction, it will be still more likely to induce ilius or enteritis. Only the milder purgatives should therefore be employed; and in general the more protracted the retention, the less irritating should be the purgative selected to remove it. The various preparations of aloes, senna, and castor oil, combined with a narcotic, as hyoscyamus, to lessen the irritation sometimes excited even by these gentle aperients, are the safest remedies; and fortunately, when judiciously combined, alternated, and repeated, they are generally effectual. In the slighter and more ordinary cases of constipation, from three to five grains cf the blue pill, with from five to ten grains of the compound gamboge, or aloetic pills, taken at bed-time, followed by a draught in the morning, consisting of equal quantities (about an ounce) of the compound infusions of senna and gentian, or about the same quantity of the compound decoction of aloes, and these doses repeated about twice a week, are all the medicines required. The remedies most appropriate for the removal of habitual and protracted constipation can be discovered only by the detection of the exact pathological condition on which the retention depends. This should be investigated with the utmost care; and when ascertained, the particular medicines, and the form of exhibiting them best adapted to the case, will be sufficiently obvious. But medicines alone, though the most judiciously chosen, and producing the best effects, will accomplish but little. The general management must co-operate with the medical treatment. There must be the strictest attention to regimen, including under this term all the known means of putting and keeping the body in general, and the disordered organ in particular, in a state of the most perfect health and vigour; namely, diet, exercise physical and mental, pure air, retirement to rest at regular and early hours, with a moderate, and only a moderate, quantity of sleep, &c. (Copland's *Dictionary of Practical Medicine*, and Southwood Smith's *Philosophy of Health.*)

CONSTITUTION, a term often used by persons at the present day without any precise notion of what it means. Such a definition of a constitution, if it were offered as one, might be defended as equally good with many other definitions or descriptions which are involved in the terms used whenever a constitution is spoken of.

The constitutions which are most frequently mentioned are the English constitution, the constitutions of the several states composing the North American union, the federal constitution, by which these same states are bound together, and various constitutions of the European continent, which have hardly been permanent enough to be submitted to an accurate investigation.

The *vague* notion of a constitution is that of certain fundamental rules or laws by which the general form of administration in a given country is regulated, and in opposition to which no other fundamental rules or laws, or any rules or laws, can or ought to be made.

The *exact* notion of a constitution cannot be obtained without first obtaining a notion of sovereign power. The sovereign power in any state is that power from which all laws properly so called proceed; it is that power which commands and can enforce obedience. Such a power, being sovereign or supreme, is subject to no other power, and cannot therefore be bound by any rules laid down, either by those who have at any previous time enjoyed the sovereign power in the same community, or by any maxims or rules of conduct practised or recommended by its predecessors in power, whether those rules or maxims be merely a matter of long usage or solemnly recorded in any written instrument. The sovereign power for the time is supreme, and can make what laws it pleases without doing any illegal act, and, strictly speaking, also, without doing any unconstitutional act. For this word constitution, taken in its strongest sense, can never mean more than a law made or a usage sanctioned by some one or more possessed of sovereign power, which law or usage has for many generations been observed by all those who have successively held the sovereign power in the same country. To modify or destroy such a rule or law might be unwise, as being an act in opposition to that which many successive generations had found to be a wise and useful law; it might be dangerous as being opposed to that to which the prejudices of many generations had given their sanction; and it might lead to resistance on the part of the governed, if either their own interest or their passions were strong enough to lead them to risk a contest with the sovereign power. If (as would generally be admitted) the assembled parliament of Great Britain and Ireland possess the sovereign power, there is no act which they could do which would be illegal, as every body must admit: and further, there is no possible act which they could do which would be unconstitutional, for such act would be no more than repealing some law or usage having the force of law which the mass of the nation regarded with more than usual veneration, or enacting something at variance with such law or usage. For example, if the next assembled parliament should abolish the trial by jury in all cases, except criminal matters, or where the crown is the prosecutor, such an act might be called by some illegal, unconstitutional, and unwise. But it would not be called illegal by any person who had fully examined into the meaning of the word law; it would not be called unconstitutional by any man who, having called it illegal, wished to be consistent with himself: it could only properly be called wise or unwise by those who had reflected sufficiently on the nature of the institution and its operations to know whether such a modification would do more good or harm.

The words constitution and unconstitutional appear to be only strictly applicable to such a case as the following; where the sovereign power being invested in one, or two, or five hundred, or all the males of an independent political community who are above a certain age, or in any other number in such a community, lays down certain rules to regulate the conduct of those to whom the sovereign power intrusts the legislative functions. Such are the Constitutions of the several states composing the North American Union, and such is the Constitution of the Federation of these several states. In these several states the people, in the mass, and as a general rule, are the sovereign. The people assembled by their delegates, named for that especial purpose, have framed the existing Constitutions; and they change the same Constitutions in the same way whenever the majority of the people, that is, when the sovereign, chooses to make such change.

These Constitutions lay down certain rules, according to which the legislative, executive, and judicial functionaries must be chosen; they fix limits to their several powers, both with respect to one another, and with respect to the individuals who compose the sovereign. 'They do ordain and declare the future form of government.' For example, the Constitution of Virginia of 1776, declares 'that all ministers of the Gospel of every denomination shall be inca[illegible]ng elected members of either House of Assembly, or of the Privy Council.' The same rule, we believe, forms a part of the recently amended Constitution of the same state. If the Virginia legislature were to pass an act to enable clergymen to become members of the House of Assembly or of the Privy Council, such an act would be unconstitutional, and no one would be bound to obey it. The judiciary, if such a matter came before it, would, in the discharge of its duty, declare it unconstitutional, and such so-called law could have no further effect than if any unauthorized body of men had made the rule.

A constitution then is nothing more than an act of the sovereign power, by which it delegates a part of its authority to certain persons, or to a body, to be chosen in a way prescribed by Act of Constitution, which at the same time fixes in a general way the powers of the body to which a part of the sovereign power is thus delegated. And the sovereign power changes this Constitution whenever it pleases, and in doing so acts neither constitutionally nor unconstitutionally, but simply exercises its sovereign power. No body can act unconstitutionally but a body which has received authority from a higher power, and acts contrary to the terms which fix that authority. Wherever then there is a sovereign power, consisting either of one, as the Autocrat of Russia, of three members, king, lords, and commons, as in England (provided these three members do possess the complete sovereign power), or of all the males born of American citizens and of a given age, as in most of the United States of North America—such sovereign power cannot act unconstitutionally. For to act unconstitutionally would be to act against a rule imposed by some superior authority, which would be a contradiction.

The policy of having a constitution in a state where the sovereign power is in the hands of the community, may be defended on general grounds of convenience. When the community have settled that certain fundamental maxims are right, it is a saving of time and trouble to exclude the discussion of all such matters from the functions of those to whom they have by the constitution intrusted legislative power. Such fundamental rules also present a barrier to any sudden and violent assumption of undue authority either by the legislative or executive, and oblige them, as we see in the actual workings of constitutions, to obtain their object by other means, which, if not less dangerous in the end, are more slow in their operation, and thus can be detected and are exposed to be defeated by similar means put in action by the opposing party. There are disadvantages also in such an arrangement. Constitutional rules when once fixed are not easily changed; and the legislative body when once established, though theoretically, and in fact too, under the sovereign controul, often finds means to elude the vigilance and defeat the wishes of the body to which it owes its existence, and from which it derives its power. One of the great means by which these ends are effected is the interpretation of the written instrument or constitution, which is the warrant for their powers. The practice of torturing the words of all written law, till in effect the law or rule is made to express the contrary of what seemed to be at first intended, appears to be deeply implanted in the English race, and in those of their descendants, who have established constitutional forms on the other side of the Atlantic. The value of all written instruments, whether called constitutions or not, seems considerably impaired by this peculiar aptitude to construe words which once seemed to have one plain meaning only, so that they shall mean any thing which the actual circumstances may require, or may seem to require.

It is beside our purpose to discuss the advantage of a Constitution in a community where the sovereign is one. Being supreme, the sovereign may change the Constitution when he pleases. It may be said that if the Constitution is good, and has been allowed to stand by several successive possessors of the sovereign power, it obtains an apparent prescriptive authority, which is the more binding on the sovereign, as the mass of the nation habitually regard the same Constitution as something which even the sovereign cannot touch with impunity. It would shock common prejudice if the actual sovereign were to violate that which has been sanctioned by his predecessors, and is recommended by an apparently higher antiquity than the power which, in the actual sovereign's hands, appears to be of more recent birth. The precise meaning of what is called the English Constitution must be got from the various writers who have made its origin and progress their study. In reading them it may not be amiss to bear in mind that the word Constitution, as used by them, has not the exact, but the vague meaning as explained above.

For the nature of a Federal Government, which necessarily implies the notion of a Constitution, see FEDERATION.

CONSTITUTIONS, APOSTOLICAL or CLEMENTINE, are a code of regulations, attributed by some ecclesiastical writers to the Apostles, and said to have been collected by Clemens Romanus. The collection consists of eight books, containing a great many precepts and rules concerning the discipline, doctrine, and ceremonies of the church.

Besides the gospels, epistles, and apocalypse, which now compose the volume of the 'New Testament,' there were, in the earliest ages of Christianity, numerous writings bearing the name of the Apostles and apostolical men, of which some are extant at the present time; and it is generally considered that two among the first in order of time are the eight books of Apostolical or Clementine canons, and the Constitutions which are the subject of the present article. That the latter once constituted a part of the New Testament is evident from the last of the apostolical canons, which states that 'The holy and venerable Bible consists of the Old Testament (of which the several constituent books are enumerated) and the New Testament, which consists of the gospels of Matthew, Mark, Luke, and John; 14 epistles of Paul; 2 of Peter; 3 of John; 1 of James; 1 of Jude; 2 of Clement, and the *Constitutions* for you that are bishops, published by me Clement in 8 books, which are not to be divulged to all, because of the mystical things contained in them; and the Acts of the Apostles.' (Labbei, *Collect. Concil.*, tom i.) One of the epistles of Clement and part of the other which is attributed to him, are included in the ALEXANDRINE MS. Epiphanius (A.D. 400) cites the Constitutions not only as the work of an honest Catholic Christian, but as the divine word and doctrine; yet in his catalogue of canonical books they are not included, and it is contended that the Constitutions now extant are not identical with those from which Epiphanius cited.

The authenticity and date of this work have been a subject of much learned contention; and though by far the greater number of critics have pronounced it to be a pseudonymous compilation, made in the third or fourth century, there have been some who support the opinion of its apostolical origin.

Those who wish to examine the state of the evidence will find in the following works, and in various others to which they refer, some useful assistance. Turrianus, who argues for the authenticity of the Constitutions, in his five books Adversus Magdeburgenses, adduces many passages from Tertullian, Ignatius, Justinus, and others, as instances of quotation from them. To this Revetus replies (Criticus Sacer, p. 115, et seq.), that since these fathers say nothing of the Constitutions by name, it is just as likely that the Constitutions are compiled from the fathers as that the fathers quoted from the Constitutions. Scultetus, another opponent of Turrian, gives, in replying to him, a full analysis of all the books of the Constitutions in his Medulla Patrum, l. ii., c. 5. Cottelerius (Apparatus Patrum Apostolicorum, tom i.) declares them to be apocryphal and pseudepigraphical, and the production neither of the Apostles nor of Clement. Tillemont expresses a similar opinion. Dallæus (in Pseudipigraphis Apostolicis, lib. iii.) dates them subsequent to the council of Nice, in A.D. 325. Le Clerc (Bibliotheca) assigns their origin to some Arian in the 4th century, in which he is followed by Robert Turner in 'A Discourse on the Pretended Constitutions,' which regards them as a compilation from numerous Constitutions, canons, travels, traditions, and liturgies, ascribed to the apostles. Bishop Pearson (On the Creed,) supposes them to have been compiled from others which were attributed to Clement, Ignatius, Hippolytus, and others; but altered and interpolated since the time of Epiphanius. Archbishops Wake and Usher, the former in 'Genuine Epistles of the Fathers,' p. 105; the latter in 'Dissert. ad Ignatium,' p. 2, consider them as apocryphal and pseudonymous; but Whiston, regardless of all such opinions, contends with great learning and warmth, in his 'Vindication of the Constitutions,' 8vo., 1715, that they are quite as authentic as the writings of the New Testament, were dictated by the Apostles and written from their mouths by Clement, and that they contain a good scheme of (Arian) faith, and form a valuable supplement to the New Testament. The Constitutions are given in the great collection of Councils by Labbe, tom. i.; in the several Bibliothecæ Patrum; in Cottelerii S.S. Patrum Opera Vera et Suppositicia. (See also Bishop Beveridge, *Codex Canonum Eccles. Primitivæ vindicatus et illustratus*; Gerhard, *Hist. Juris Eccles.*, num. 122; Hoffmanni, *Lexicon*; Lardner's *Credibility*, vol. iv., p. 320-354; Lenglet, *Tab. Chronol.*, tom. ii., p. 212; Jortin's *Remarks on Eccles. Hist.*, vol. i., p. 228.)

CONSTITUTIONS, ROMAN. The word constitutio (from constituere, *i.e.*, to set up, to establish), signifies any disposition or appointment; for example, in D. iv. 2, l. 9, § 3, a decree of the prætor is called constitutio. The decrees and decisions of Roman emperors are also called constitutiones; and, according to Gaius (i. 5), an imperial constitution is what the emperor declares by a decree, or an edict, or a letter. That modern signification of the term, which denotes the fundamental law of a state, was not in use among the Romans; yet Cicero (*de Republica*, i. 45) employs the word to express a similar notion.

During the republic the Roman law was made or developed by decrees of the people in the comitia (leges and plebiscita), by decrees of the senate, and by the edicts of various magistrates, as the prætors and ædiles. [ROMAN LAW.] After the great internal change and revolutions had taken place in the Roman state, and Augustus had united in himself the powers of all the branches of government, with the direction of the senate, and of the assemblies of the people, the imperial power was firmly established. The emperor not only had the right of issuing edicts, as the magistrates of the republic had done, but he could propose and make entirely new laws. Propositions of laws from the emperor to the senate were called orationes principum. Thus arose the imperial constitutions, with the supremacy of Augustus. But as the arbitrary acts of Sulla, Pompeius, and Julius Cæsar, were ratified and confirmed by the people, both in their lifetime and after their death, this may be considered as the beginning of the system of constitutions. As the institutions of the republic only gradually merged into the imperial autocracy, the voice of the people in the comitia and the decrees of the senate were still respected in form, though not in substance. But after A.D. 24, during the reign of Tiberius, the legislation of the people, and 200 years later, the decrees of the senate also, totally ceased. From that æra laws were made only by the emperors; and from the time of Constantine the Great, the constitutions were properly called leges novæ, or new laws.

The imperial constitutions occur under different denominations; as edicta (leges edictales), or decrees addressed to and binding on all Roman subjects; decreta or rescripta, which are decisions in particular cases, upon questions proposed to the emperor by public functionaries or private persons; these decisions also were universally binding. We find the terms epistolæ also used, when the decisions were answers to magistrates, and litteræ when given in reply to private persons. Important single constitutions were often called, from the emperor who made them, 'lex Anastasiana.'

In course of time the number of these constitutions became so great, that to prevent confusion collections were made, and called codes. The first collections made by private persons were the codices Gregoriani and Hermogeniani, of which we know very little; it being even uncertain if they were two separate codes or only one. Yet it seems that the first collector was Gregorius, and that Hermogenes continued the work. Opinions vary also as to the time when these compilers lived. Their collections, which contained the constitutions from the time of Hadrian to Diocletian, are lost, and we have only some fragments, which were first edited by Jac. Sichardus (Basil, 1528, fol.), together with the Codex Theodosianus. The fragments are in Schulting's 'Jurisprud. Vet. Antejust.,' Lugd. Bat. 1712, and in the 'Jus Civile Antejust.,' Berol. 1815.

Another and more important collection was made under the reign of Theodosius II., by public authority. The emperor having nominated, in the year 435, a commission of sixteen persons, under the direction of Antiochus, for the purpose of collecting the constitutions from the time of Constantine the Great, three years afterwards (A.D. 438), the new code, called Codex Theodosianus, was confirmed by the emperor, and published in the eastern empire. It contains sixteen books, divided into titles, in which the separate constitutions are arranged, according to their subject-matter, in such a way that many of them are subdivided. Some additions, called novellæ, were afterwards made to the collection of Theodosius. The first five books were lost, but some parts of them have been recently discovered at Milan, by Clossius (Clossii 'Theodos. Codic. Genuin. Fragmenta,' Tüb. 1824); and at Turin, by Peyron, ('Codic. Theodos. Fragm. Ined.,' Tur., 1823-4.) The best edition of the Theodosian Code is that by Jac. Gothofredus, tom. vi., Lugd., 1665, who also wrote an excellent commentary on it, which was published, together with the text, by Ritter, Leipzig, 1736-54.

In the year 506, Alaric II. made an abridgement of the Theodosian Code, adding to it the excerpts from the codices Gregoriani and Hermogeniani, and of the works of the Roman lawyers Gaius and Paulus, for the use of the Romans then living in the empire of the Visigoths: the collection is called 'Breviarium Alaricianum.'

The last and most important collection of Roman constitutions was made by the order of Justinian. [JUSTINIAN'S LEGISLATION.]

CONSTRUCTION (geometry), all formation of lines, figures, &c., which is not absolutely implied in the hypothesis of the problem or theorem in question. Thus, in the proof of the theorem, 'the square on the hypothenuse of a right angled triangle is equal to the sum of the squares on the sides,' the formation of the right-angled triangle and of the squares is not technically considered as part of the construction, the latter term being only used to imply all the additional formation of figure necessary to the proof.

A question is frequently said to be solved by construction, when it is only meant that a geometrical method of solving it is adopted [SOLUTION, GEOMETRICAL], as distinguished from an algebraical solution. An equation is also sometimes said to be constructed, in the sense inverse to that in which it is said to be solved; that is, when the roots are given, and the equation is required to be found. [EQUATIONS, THEORY OF.]

CONSUBSTANTIAL (Consubstantialis) is equivalent in expression to co-essential, and is the translation of the term *ὁμοουσίος*, homoousios, which, in the commencement of the fourth century, was the subject of so much zealous contention among the Trinitarian and Unitarian sects of Christians. The Arians and Eusebians, who asserted the second person of the Trinity, and the adherents of Macedonius, who asserted the third person, to be different and distinct in nature from the first, were strenuously opposed by the Athanasians, who, at the council of Nice (A. D. 325), adopted as the pass-word of their party the term *ὁμοουσίος*, consubstantial, or, as it is Englished in the Nicene creed, '*Of one substance* with the Father.' There were three conflicting denominations: those who held the three persons to be of the *same* substance, *ὁμοουσίος*; those who asserted them to be of a *similar* substance, *ὁμοιουσίος*; and those who contended that they were of a *different* substance, *ἀνομοῖος*. Between these parties the dispute was carried on during several years with great violence; and successive councils, composed of hundreds of bishops, continued to meet for the purpose of altering creeds and reciprocating anathemas. In modern times the *ἀνομοῖος* doctrine has been advocated by Dr. Bury in his 'Naked Gospel,' a work which, though condemned and burnt by the University of Oxford, was approved and adopted by Locke, Clarke, and Whiston. The circumstantial particulars of the antient controversy may be found in the various histories of the councils of that period, and its modern revival in the numerous works on the Unitarian doctrines. See especially the article 'Arianisme,' in Plugnet's *Dict. des Hérésies.*

CONSUBSTANTIATION, or IMPANATION, is a term adopted by the Lutheran Church to designate its doctrine of the Eucharist, in contradistinction to the transubstantiation of the Church of Rome. Luther, after separating from the Catholic communion, still retained the doctrine of the real presence; but instead of teaching, as the Romanists do, that the priest's pronunciation of the words of consecration at once deprive the bread and wine on the altar of their natural qualities, and transform them into the real body and blood of Christ, he taught, that after the consecration of the bread and wine, they are mysteriously *accompanied* with the real body and blood. In short, in *transubstantiation*, the divine body and blood is present *without* the bread and wine; and in *consubstantiation* it is present *with* the bread and wine: the former effects a change of nature, the latter a change of circumstance.

The Lutheran doctrine of consubstantiation was first introduced into the church by John, surnamed Pungens Asinus, a doctor of Paris, at the end of the thirteenth century. His work on this subject, entitled 'Determinatio F. Joannis Parisiensis de modo existendi Corpus Christi in Sacramento Altaris,' was republished by Allix in 1686.

CONSUL (a word of the same family as *consulere*, to consult), was the title of the highest ordinary magistrate in the Roman republic. King Tarquinius Superbus having been expelled from Rome for his tyrannical conduct, by the joint efforts of the patricians and plebeians, B.C. 409, a republic was established. Instead of kings, two functionaries called consuls (consules, in Greek ὕπατοι) were appointed to administer the republic. The first consuls were Lucius Junius Brutus and Lucius Tarquinius Collatinus (or M. Horatius, according to Polybius, iii. 22). The consuls were annually elected in the Comitia Centuriata, and at first only chosen from the patricians.

As the consulship was established in the place of the kingly office, the consuls also were invested with the same power that the kings had. (Niebuhr's *History* and Gibbon's *History*, i. 3; Cicero, *De Leg.* iii. 3, who ascribes to them 'regiam potestatem.') The consulate was, with the exception of the dictatorship, the highest, and, before prætor, ædiles, and censors existed, the only superior administrative office in Rome. The consuls were at the head of the whole republic: the judiciary (jurisdictio), the military (imperium), and the executive powers were all united in them. Accordingly, we find them also called prætores, and judices, and imperatores. They presided in the senate, where they had an elevated seat, and the business in the comitia curiata and centuriata was conducted by them. The consuls created the quæstors of the public treasury, and thus had great influence in the administration of the treasury, the quæstors being dependent on them. They could also conclude peace and make alliances. They were the supreme judges in all suits and criminal trials.

The consuls possessed the same external insignia of honour as the kings, except the golden crown and the trabea (purple cloak), which latter they were only allowed to wear in a triumph. They had a sceptre of ivory, with an eagle at the end. In the assemblies of the people they sat on the sella curulis (an ornamented chair); and like the other senators they wore the toga prætexta. Twelve lictors, with the fasces and axes, as the symbol of the consuls' power over the lives of the citizens, preceded each of them at first; but P. Valerius, called Poplicola, a name which implies his respect, or affected respect, for popular rights, limited the power of the consuls, and curtailed the external symbols of their authority. In the city, the axes were taken from the fasces, and only one of the consuls was preceded by the twelve lictors.. From their sentence appeals to the people were allowed. From this time they were deprived of their former power of condemning citizens to death in Rome, and the power of scourging them only remained. But while they were at the head of the army out of Rome, they retained the axes in the fasces and all their former rights. The consul who, according to the settlement of Valerius, was not preceded by the twelve lictors, had a public slave, called accensus, to precede him. The right to the twelve lictors and the supreme authority in matters of administration were enjoyed by the consuls alternately from month to month.

The patricians, after expelling the kings with the help of the plebeians, designed to transfer the royal power to themselves, which they accomplished by securing the election of both consuls out of their own body. The consuls therefore being invested with the supreme power, the struggle of the people with the patricians was at the same time a struggle against the consuls. Their power sustained a great shock by the institution of the tribunes of the plebs. Each of the tribunes, whose number at last amounted to ten, had the right of putting his veto on the measures of the consuls. In order to prevent arbitrary acts of the consuls, the tribune Terrentius, B.C. 461, made a proposition for a code or collection of laws, and in the year B.C. 452 ten men (decemviri) were named for this purpose, who were invested with full powers, and all other functionaries for the time were suspended. The consulate being re-established, the tribunes, B.C. 444, proposed that the people should choose consuls from the plebeians also, a proposal which gave rise to a long and violent contest. The consulship was again suspended, and tribunes of war (tribuni militares) with consular power were appointed, to which office plebeians also were made eligible. At last, B.C. 366, the first plebeian was elected consul. (Liv. vi. 42 vii. i. 2. 31.

Afterwards both consuls were on several occasions plebeians.

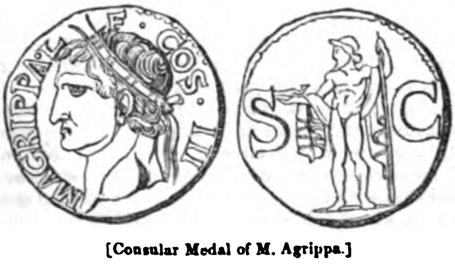
In the mean time the extension of the state made it impossible for the consuls to perform the increased duties of their office, and new functionaries were created. In B.C. 442, the censors, and B.C. 365, the prætors, were created, which latter had the judicial functions previously attached to the consulate. In relation to these new magistrates, the consul was called magistratus major, or superior magistrate.

Though the consular power was thus much diminished, it was still very great. All the officers of the state, except the tribunes, were under the consuls; they summoned the meetings of the senate, received all dispatches, and gave audiences to foreign ambassadors. In time of war they were commanders-in-chief, and the election of the military officers partly depended on them. In critical times the consular power was made unlimited by the decree of the senate, 'videant consules ne quid respublica detrimenti capiat' (they should take care that the republic sustained no harm). Under such circumstances they could require the strictest obedience from all the citizens; and they resumed their right to condemn to death without appeal.

The imperium or military command was granted to the consuls by the lex curiata [COMITIA], whereby a province (*provincia*) was assigned to them. The term *provincia* originally denoted the power given to discharge some public duty out of Rome, particularly the command of the army in conquered countries; and these countries themselves were called provinciæ (provinces). When a consul, after the expiration of his term of office, was appointed to govern a province, he was called pro-consul.

At first no particular age was a necessary qualification for the consulate. But by the lex Annalis, proposed by the tribune L. Villius, in the year B.C. 181, a certain age was required for each magistrate; and the consul must be forty-three years of age. But this law was not always observed; M. Valerius Corvus was elected consul in his twenty-third, and Scipio Africanus in his twenty-eighth year. No one could legally be re-elected till after an interval of ten years; but M. Valerius Corvus was re-elected six times, and Marius seven times.

The candidate for the consulate was required to be at Rome when the election took place in the comitia centuriata, a rule which was also sometimes not regarded. The elder of the two consuls first received the fasces, until the Emperor Augustus prescribed, by the law called lex Julia and Papia Poppæa, that he should take them first who had most children. The time of election varied at different periods of the Commonwealth; but they were always chosen some time before they entered on office, and were called designati. The time of entrance on office likewise varied; but about B.C. 154 it was fixed that they should always enter on their office on the 1st of January. The years were named after the consuls, and annual registers were kept for that purpose, which were called fasti consulares. When the consuls entered on their office, they went in a solemn procession to the capitol to sacrifice to Jupiter Capitolinus; and after this ceremony the senate held a solemn session. Within the five next days they were to take the oath to administer the republic according to the laws; and at the end of their term of office they took a similar oath. Those who had discharged the office of consul were called consulares, and enjoyed a kind of preeminence in rank over the other senators.



[Consular Medal of M. Agrippa.]

British Museum. Actual size. Bronze. Weight, 158 grains.

From the time of Sulla and Cæsar, who were elected perpetual dictators, the consulate gradually lost all its powers, and under the emperors it sunk to a mere shadow and a name. Yet consuls were still annually elected by the people, until the time of Tiberius, who ordered that they should be chosen by the senate. The number of the consuls was much augmented by the emperors; and several kinds of consuls were made, as consules ordinarii, after whom the years still were called; consules suffecti, elected by the emperors; and consules honorarii, who had title and rank, but no power. The last consul after whom the year was denominated, was Basilius, junior, in the year 1294 A.U.C. or 541 A.D., in the reign of the Emperor Justinianus.

CONSUL, an officer appointed by a government to reside in some foreign country, in order to give protection to such subjects of the government by whom he is appointed as may have commercial dealings in the country where the consul resides, and also to keep his employers informed concerning any matters relating to trade which may be of interest or advantage for them to know. To these duties are sometimes superadded others having objects more directly political, but into this part of a consul's duty it is not necessary to enter at present, as such functions are assigned to consuls not as such, but in the absence of an ambassador or other political agent. The duties of an English consul, as such, cannot perhaps be better described than by giving the substance of the general instructions with which he is furnished by the government on his appointment.

His first duty is to exhibit his commission, either directly, or through the English ambassador, to the authorities of the country to which he is accredited, and to obtain their sanction to his appointment: the document whereby this sanction is communicated, is called an exequatur; its issue must precede the commencement of his consular duties, and its possession secures to the consul 'the enjoyment of such privileges, immunities, and exemptions, as have been enjoyed by his predecessors, and as are usually granted to consuls in the country in which he is to reside.' It must be the particular study of the consul 'to become conversant with the laws and general principles which relate to the trade of Great Britain with foreign parts; to make himself acquainted with the language and with the municipal laws of the country wherein he resides, and especially with such laws as have any connexion with the trade between the two countries.' It is the consul's principal duty 'to protect and promote the lawful trade and trading interests of Great Britain by every fair and proper means;' but he is at the same time 'to caution all British subjects against carrying on an illicit commerce to the detriment of the revenue and in violation of the laws and regulations of England, or of the country in which he resides;' and he is to give to his own government notice of any attempt at such illicit trading. The consul is 'to give his best advice and assistance, whenever called upon, to his Majesty's trading subjects, quieting their differences, promoting peace, harmony, and good-will amongst them, and conciliating as much as possible the subjects of the two countries upon all points of difference which may fall under his cognizance.' Should any attempts be made to injure British subjects in person or in property, he is to uphold their rightful interests and the privileges secured to them by treaty. If, in such cases, redress cannot be obtained from the local administration, he must apply to the British minister at the court of the country in which he resides, and place the matter in his hands. The consul must transmit to the Secretary of State for Foreign Affairs, at the end of every year a return of the trade carried on at the different ports within his consulate, according to a form prescribed. He is also required to send quarterly an account of the market prices of agricultural produce in each week of the preceding three months, with the course of exchange, and any other remarks which he may consider necessary for properly explaining the state of the market for corn and grain. It is further his duty to keep his own government informed as to the appearance of any infectious disease at the place of his residence. The consul is required to afford relief to any distressed British seamen, or other British subjects thrown upon the coast, or reaching by chance any place within his district, and he is to endeavour to procure for such persons the means of returning to England. He is to furnish intelligence to the commanders of king's ships touching upon the coast where he is, and to obtain for them, when required, supplies of water and provisions, and he is to exert himself to recover all wrecks and stores belonging to king's ships when found at sea, and brought into the port where he resides.

In most cases consuls are subjects of the state by whom they are appointed, but this is by no means an invariable rule, and they are sometimes the subjects of the country in which they reside, or of some other country foreign to both. Persons are usually selected for filling the office from among the mercantile class, and it very commonly happens that they are engaged in commercial pursuits at the port where their official residence is fixed. In this respect the English government is chargeable with some inconsistency, for while, in many instances, British consuls are permitted to trade, in others they are expressly interdicted from so doing. It would be difficult to discover the application of any fixed principle in determining the places where either of these opposite rules has been adopted. We believe the interdiction to be of modern application, and that the desire of diminishing the public expense has since led, in many cases, to the relaxation of what was once intended to be made a general rule, it being necessary to give a higher salary whenever trading is not allowed. Many traders are willing to undertake the office at a low rate of direct remuneration for the sake of the commercial influence which it brings, and which is frequently of far greater value to them than any salary which the government would give. The policy of this kind of economy has been much questioned.

The number of consuls and vice-consuls appointed by the English government, and their distribution in the year 1835, were as under:—

	Consuls-General.	Consuls.	Vice-Consuls.	Unpaid Vice-Consuls.
Russia	1	5	1	5
Sweden	0	2	0	14
Norway	0	2	0	16
Denmark	0	1	1	6
Prussia	0	1	4	2
Hamburg	1	0	1	Germany. 7
Bremen	0	0	1	
Lubeck	0	0	1	
Cuxhaven	0	0	1	0
Holland	0	2	0	7
Belgium	0	2	0	3
France	0	11	1	29
Spain and Spanish Colonies	0	12	1	58
Portugal	1	3	5	19
Italy	0	8	3	34
Austria	1	1	3	2
Sicily	0	0	0	10
Greece	0	2	2	14
Turkey	1	2	8	6
Syria	1	2	2	1
Egypt	1	1	2	3
United States of America	0	9	1	16
Mexico	1	0	3	1
Guatemala	0	1	0	0
Columbia	0	5	1	2
Brazil	0	4	2	3
Monte Video	1	0	0	0
Buenos Ayres	0	1	0	0
Chili	1	2	1	0
Peru	1	1	1	1
Hayti	0	1	2	2
Sandwich Islands	0	1	0	0
	11	82	48	261

The salaries paid vary not only in the manner above stated, but likewise according to the particular circumstances attending the appointment, a residence in some countries being necessarily more expensive than in others.

The total amount paid in salaries to English consuls and vice-consuls in 1835 was 61,950*l.*; in 1825 the amount was 71,716*l.* In addition to their salaries, consuls are in the receipt of fees on signing various documents, but these fees are of small amount. In 1834 only 12,143*l.* was divided among the whole number in unequal proportions: the largest, at Rio de Janeiro, in that year was 980*l.*; while, in some cases, the sum did not exceed one or two pounds.

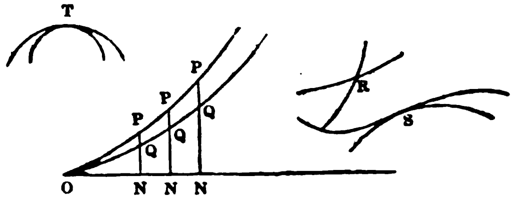
CONSUMPTION, PULMONARY. [PHTHISIS PULMONALIS.]

CONSUMPTION, MESENTERIC. [MARASMUS.]

CONSUMPTION, in political economy, is the end of production; the use, the expenditure, of articles produced. It is unnecessary here to enter upon any examination of the theories of *productive* and *unproductive* consumption, which have so largely occupied the attention of writers upon political economy. We have stated the general principle under the head ACCUMULATION. The natural relations between production and consumption appear very unlikely to be greatly disturbed in any condition of society in which there is freedom of labour and security of property. The most injudicious and extravagant consumption on the part of the few is, in its degree, a stimulus to a more strenuous production on the part of the many; and under these circumstances there is sure to be that excess of production over consumption which constitutes capital. The creation of capital shows that the production has been greater than the unproductive consumption. A judicious and well-regulated expenditure on the part of the few would doubtless afford a more certain encouragement to the industry of the producers, and the excess of production over consumption would, in the long run, be greater. Whatever injury the improvident consumption of individuals may cause to themselves, it is quite clear that the producing class of society will always repair the waste of the spending class; that in point of fact there will be an excess of production over consumption, wherever the course of industry is not impeded by bad laws, or by a wasteful consumption on the part of a government. Whenever a government engages in the ruinous consumption incidental to war, for example, a very powerful stimulus may indeed be given to particular branches of industry; but other branches of industry that would have been encouraged had their money remained in the pockets of the tax-payers, will proportionately be depressed. The compensating power of production that is called forth in all cases of private consumption must be deranged, or unequally and therefore imperfectly excited, by the consumption of the state.

CONTACT. (Geometry.) Two lines, one of which at least is curved, are said to be in contact when they have a common point, and recede from that point in such a way that the deflection of the one from the other will, if a sufficiently small departure be taken, become as small a fraction as we please of that departure; that is, if there be no limit to the smallness of the ratio which P Q may be made to bear to O N, as we approach the point O. The subject will be further discussed mathematically in TANGENT, CURVATURE, CURVES (THEORY OF),—SURFACES (THEORY OF); and we shall at present confine ourselves to pointing out the connexion between the preceding definition, which is refined and mathematical, and the obvious ocular phenomenon, by perception of which we immediately admit a marked difference of character between *contact*, as shown at S, and simple *intersection*, as shown at R.

All our perceptions of lines being ocular and physical in the first instance, there is a *minimum visibile*, or least visible distance, at which lines will run into each other. Now if P Q and O N always preserve such a ratio to each other that the *minima visibilia* of these lines arrive nearly together, P Q will not be lost to sight before O N, and the curves will continue distinct up to the very point of meeting. But if P Q diminish so rapidly as compared with O N, as to be lost to sight while O N is still visible as a length, the two curves will appear to coincide for a visible length, which forms the principal ocular feature of contact. But this *practical* contact is not admitted in geometry, a science of reason, in which no length is considered as invisible; so that contact is only said to exist where the ratio of P Q to O N diminishes—not merely very much—but without limit. Let O N and P Q be the fractions x and v of a linear unit. If then v diminish without limit when compared with x, but always retain a finite ratio to x^2, the contact is said to be *of the first order*; if v also diminish without limit when compared with x^2, but always retain a finite ratio to x^3, the contact is said to be of the second order, and so on. These different orders of contact exhibit nothing to the eye but a closer approach, the higher the order of contact; except in this, that contacts of an even order are always accompanied by the *intersecting* coincidence shown at S, while contacts of an odd order make the curves tangent to each other in the sense in which the word is used by Euclid.



CONTAGION, THE MATTER OF, a poison which, on entering the blood, produces a definite train of morbid phenomena, and which communicates to the blood the property of generating a similar poison, capable of producing precisely similar morbid phenomena. Considered as a morbific matter *sui generis*, contagion, then, is an agent which produces a disease of a definite nature, one of the distinctive characters of which is that in its progress a peculiar matter is secreted from the blood, which, when introduced into the blood of another individual, produces precisely the same disease. The term contagion is also in common use to denote the actual propagation of diseases of a specific nature from person to person. Such diseases, so propagated, are called contagious; and the matter by which they are propagated is called contagious matter or contagion.

The disease called small-pox exhibits a series of morbid phenomena peculiar to itself. These peculiar phenomena constitute it a distinct or generic disease. The pustules formed in its progress, the formation of which is one of the series of morbid phenomena distinctive of it, contain a peculiar secretion, a specific poison, which, on being introduced into the blood of a person previously in sound health, as by inoculation, produces in that person small-pox. This disease, then, presents all the characters of a contagious disease.

According to the etymological signification of the term, the propagation of disease from person to person by contagion depends on the actual contact of the body which receives with that which communicates the poison. But direct contact is not indispensable to the propagation of a contagious disease. There are contagious diseases which are absolutely incommunicable without direct contact; but there are others which are capable of communication both by contact and without it. A particle of the matter of small-pox, for example, placed in direct contact with the body, will produce small-pox; but the matter of small-pox is likewise capable of being dissolved or suspended in the air; and the air thus loaded with small-pox matter, on coming in contact with the body, is capable of producing small-pox. Hence contagious diseases are divided into two great classes; into those in which the contagious matter acts only by positive contact of person with person, and into those in which it acts both by positive contact and through the medium of the air. Contagion may therefore be said to be immediate or mediate, contactual or remote.

Contagion is carefully to be distinguished from infection. The distinction is clear and broad. From not regarding it, medical men have fallen into the grossest errors, both in their so-called facts and in their reasonings. It is of great importance, theoretically and practically, that this distinction should be understood; it is a subject in which, on many accounts, the public has a deep interest; and an attempt will be made to elucidate it under the article Infection. [INFECTION.]

CONTARINI, an illustrious family of Venice, which has given to the republic many senators, doges, and statesmen. The first doge of the name was Domenico Contarini, in the eleventh century; another, Andrea Contarini, was doge during the war of Chiozza. After the Genoese had taken that place, and were threatening the very existence of Venice, in 1380, Contarini, then eighty years of age, led the Venetian fleet against the enemy; and being assisted by Vettor Pisani and Carlo Zeno, he defeated the Genoese, retook Chiozza, and thus saved the republic. Ambrogio Contarini was sent, in 1473, by the republic, then at war with Mahomet II., as ambassador to Hussum Hassan Bey, sovereign or usurper of Persia, to contract an offensive alliance against the Ottomans. The coasts of Asia Minor and Syria being occupied by the Turks, Contarini was obliged to take his way through Poland and Tartary to Caffa in the Crimea, from whence he crossed the Euxine to the mouth of the Phasis, and thence proceeded through Mingrelia and Armenia to Persia. He met Hussum Hassan at Ispahan, accompanied him to Tabreez, and then returned homewards by Derbent and the Caspian Sea to Astrakhan, and thence to Moscow, where he was well received by the grand duke of Muscovy. He returned to Venice in 1477, and published the journal of his mission, which is curious, and written with much apparent regard to truth. 'Itinerario nell' Anno 1473, ad Usun Cassan Ré di Persia,' 4to., Venezia, 1524. Hussum Hassan attacked Mahomet, while the Venetian fleet was ravaging the coasts of Asia Minor; but the Persians were defeated by the Turks near Trebizond, and the alliance led to no other result than to effect a temporary diversion in favour of Venice. There have been also several men of learning of the family of Contarini, such as Cardinal Gaspare Contarini, in the sixteenth century, who was employed on several important missions, and wrote many philosophical and theological works; among others, 'De Immortalitate Animæ adversus Petrum Pomponacium,' 'De Libero Arbitrio et Prædestinatione,' and also a treatise, 'De Magistratibus et Republica Venetorum.' His works were collected and published together at Paris, folio, 1571. Vincenzo Contarini was professor at Padua at the beginning of the seventeenth century. He wrote several works on classical erudition; 'De re frumentaria,' 'De Militari Romanorum Stipendio,' and 'Variarum Lectionum Liber.'

CONTEMPT. A contempt in law is a disobedience of the rules, orders, or process of a court of justice, or a disturbance or interruption of its proceedings. Contempts by a contumacious resistance to the process of a court, such as the refusal of a sheriff to return a writ, are punishable by attachment; but contempts done in the presence of the court, which cause an obstruction to its proceedings in administering the law, may be punished or repressed in a summary manner by the commitment of the offender to prison or by fining him. The power of enforcing their process, and of vindicating their authority against open obstruction or defiance, is incident to the nature of all courts; and the means which the law intrusts to them for that purpose are attachment for contempts committed *out of* court, and commitment and fine for contempts done *in facie curiæ*. [ATTACHMENT.] (See Viner's *Abridgement*, tit. 'Contempts.')

CONTENT (contentus, contained), the quantity of space contained in any portion of space, measured by the number of times which some arbitrary unit is contained in the space. Thus, linear content is simply LENGTH; superficial content is AREA or surface; solid content (in which sense the word is principally used), also called volume, is the number of solid units contained in a space. These solid units are always cubes, described in the unit of length. Thus, when the inch or foot is employed in measuring lengths, the cubic inch or cubic foot is always employed as the measure of solid content.

The solid content of a parallelopiped (or figure like a box) is found by multiplying together the units in the lengths of its three dimensions. Thus, 3 feet of length, $2\frac{1}{2}$ feet of breadth, and 4 feet of height, give $3 \times 2\frac{1}{2} \times 4$, or 30 cubic feet.

The solid content of any cylinder or prism is found by multiplying together the number of square units in the base and the number of linear units in the altitude; and one-third of a similar product is the content of a pyramid or a cone. The content of any irregular solid bounded by planes must be found by dividing it into pyramids.

Weight is thus connected with content accurately enough for common purposes. Multiply the number of cubic *feet* by 1000 times the specific gravity; the result is the number of ounces avoirdupois. Roughly, multiply the number of cubic feet by the specific gravity, and five-ninths of the result is the number of cwts. Thus, the specific gravity of brick being 2, a cube of bricks 20 feet long every way weighs $\frac{5}{9}$ of $20 \times 20 \times 20 \times 2$, or 8889 cwt.

To find the solid content of a sphere, take $\frac{377}{90}$ths of the rad. × rad. × rad. Thus, the radius of a sphere being 4 feet, the number of cubic feet contained is $4 \times 4 \times 4 \times 377 \div 90$, or 268·1.

CONTINENTAL SYSTEM, the phrase used by Bonaparte to designate his scheme for combining the strength of the Continent against Great Britain. It was in part developed in the Berlin decree, issued 21st November, 1806, which declared that the British islands were to be considered as in a state of blockade by all the Continent; forbade under severe penalties all correspondence or trade with England; ordered all letters to and from England to be detained and opened at the post-offices; denounced as contraband all articles of English manufacture, or the produce of the British colonies; and declared property of every kind belonging to British subjects, wherever found, to be lawful prize. From this time Bonaparte adopted it as the rule of his policy to compel all the continental powers who would remain at peace with him to comply with these commercial regulations, and in addition to seize and imprison all English subjects found within their dominions.

CONTINUED BASE, in Music, is the figured base of a score used throughout, and so called to distinguish it from the vocal base, as well as from the base staves assigned to particular instruments. The term is only to be found in very old music, and is now become obsolete.

CONTORTÆ. [Apocynaceæ.]

CONTRABAND, from the Italian *Contrabando*, against the proclamation, a term commonly used in commercial language to denote articles the importation or exportation of which is prohibited by law. Since the adoption of the warehousing system in this kingdom, the list of goods the importation of which is prohibited has been made exceedingly short; it comprises at this time (1836) only the following articles:—

Arms, ammunition, and utensils of war, by way of merchandize, except by license from his Majesty for the public stores only.

Books first printed in the United Kingdom, and reprinted in any other country and imported for sale.

Cattle, sheep, swine, lamb, mutton, beef or pork, fresh or corned, or slightly salted.

Clocks or watches, with any mark or stamp representing any legal British assay mark or stamp, or purporting to be of British make, or not having the name and abode of some foreign maker visible on the frame and the face, or not being complete.

Coin, counterfeit, or not of the established standard in weight and fineness.

Fish of foreign taking or curing, or in foreign vessels, except turbots, lobsters, stock-fish, live eels, anchovies, sturgeon, botargo, and caviare.

Malt.

Snuff-work, tobacco-stalks, and tobacco-stalk flour.

The list of articles contraband as regards exportation from the United Kingdom is still more limited, and is in fact included under three heads: viz.

Clocks and watches: the outward or inward case or dial-plate of any clock or watch without the movement complete, and with the clock or watchmaker's name engraved thereon.

Lace made of inferior metal, in whole or in part, to imitate gold or silver lace.

Tools, utensils, and machinery.

The schedule of prohibitions to importations was formerly much more extensive. As it stands at present, if we except those articles which are introduced for the protection of agriculture, warlike stores, and fish, the insertion of which last is intended for the encouragement of a branch of native industry, the list is calculated only for the prevention of fraud. The same might be said of the second list, if it did not contain the prohibition to export tools and machinery; this restriction has of late years been very much relaxed under the power given by Act of Parliament to the Board of Trade to license upon application the exportation of such tools and machines as in the opinion of the Board may without inconvenience be allowed to go out of the country; and at present the restriction is limited almost entirely to machinery required for the prosecution of the processes of spinning various kinds of yarn.

There are some other prohibitions by which trade in certain articles is restricted; but these refer to the manner in which the trade may be conducted, as the size of the ship, or the package, or the country from or to which the trading may take place, and these being only of the nature of regulations, the articles in question cannot be considered contraband. Of this nature are the prohibitions which extend to our colonies, and which have for their object the encouragement of the trade of the mother country. The list of articles prohibited by many foreign countries is much larger than that enforced in this country; though the system in the case of some of those countries has of late been somewhat relaxed. The tariff of Russia is however still principally filled by designating articles which are contraband.

Another sense in which the term contraband is applied refers to certain branches of trade carried on by neutrals during the continuance of war between other countries. It has always been held under these circumstances, that belligerents have a right to treat as contraband, and to capture and confiscate, all goods which can be considered munitions of war, under which description are comprehended everything that can be made directly and obviously available to a hostile purpose, such as arms, ammunition, and all kinds of naval stores, and all such other articles as are capable of being used with a like purpose, such as horses, and timber for building ships. Under some circumstances, provisions which it is attempted to convey to an enemy's port are contraband, as when a hostile armament is in preparation in that port. These restrictions rest upon principles which are reasonable in themselves, and have been generally recognised by neutrals; others which have at various times been enforced or attempted to be enforced have been contested, but a description of this branch of the subject belongs rather to the matter of International Law, than to a description of contraband trading.

CONTRACT. [Agreement.]

CONTR' ALTO; CONTRATENOR. [Alto.]

CONTRARY and CONTRADICTORY. Two propositions are contrary when the one denies every possible case of the other: they are contradictory, when one being universal, the other denies some only of the things asserted in the first. Thus the contrary proposition to 'every A is B' is 'no A is B,' and its contradictory is 'some As are not Bs.

Contrary propositions may be both false, but cannot be both true; as in 'all angles are equal,' and 'no angles are equal.' But of contradictory propositions one must be true and one must be false; either 'all angles are equal,' or 'some angles are not equal.' One of the most common fallacies of conversation and debate (and occasionally of written argument) is fixing the assertion of the contrary upon one who simply contradicts. And on the other hand, nothing is more common than to assume a contrary as proved upon grounds which establish only the contradictory.

The most easy way of establishing general propositions is, in many cases, the refutation of the contradictory; and here is another source of error, since the refutation of the contrary is frequently supposed to have the same effect.

CONULA'RIA. [Orthocerata.]

CONULI'NA. [Polypiaria Membranacea.]

CO'NULUS. [Echinodermata.]

CONUS (zoology), a genus of gasteropodous mollusks, founded by Linnæus; and though multitudinous in species, left untouched by modern zoologists, with the exception of De Montfort.

Animal elongated, very much compressed and involved, with a very distinct head, terminated by a proboscis capable of much extension; *mouth* with a tongue rather short, but projecting, and armed with two rows of sharp teeth; tentacula cylindrical, carrying the eyes near the summit; foot oval, elongated, wider before than it is behind, with a transverse anterior channel; *mantle* scanty, narrow, forming an elongated siphon in front.

Shell thick, solid, rolled up, as it were, in a conical form; epidermis membranous, sometimes very thick; spire of different degrees of elevation, sometimes almost flat; aperture long and very narrow, widening a little anteriorly; lips generally straight and parallel, the outer lip simple and sharp-edged, sometimes a little curved, the inner lip without any plaits on the columella, but with a few elevated striæ on its anterior termination. *Operculum* horny, very small, subspiral, with a terminal summit, placed obliquely on the back part of the foot, and, when compared with the length of the aperture, appearing like a rudiment.

Geographical Distribution.—Southern and tropical seas. The form becomes gradually less developed as the locality approaches the north. In the Mediterranean there are a few species, but none appear to have been detected in the northern seas.

Habits.—Carnivorous. Found on sandy mud at depths varying from near the surface of the sea to seventeen fathoms.

The species are very numerous. Lamarck records 181 recent; and several of these include varieties. Deshayes in his Tables gives the same number. To these must be added one new species described by Mr. G. B. Sowerby in his 'Genera,' four new species brought to this country by Lieutenant Belcher, R.N., and by the Blossom, described by Mr. Broderip and Mr. G. B. Sowerby (*Zool. Journal*, vols. iv. and v.), together with six new species and some varieties described by Mr. G. B. Sowerby, and thirteen new species and several varieties described by Mr. Broderip from Mr. Cuming's collection (*Zool. Proceedings*). The following observations of Mr. Broderip in his introduction to the descriptions may be of use to the student. After pointing out the difficulty of the task arising from the infinite varieties presented by the genus, and the very few points of form and structure in the shell that can be relied on as the foundation of specific character, the author thus continues: 'M. de Blainville, when noticing the numerous species already recorded, gives us a hint that many of them may be what Adanson calls "espèces de cabinet," and no one can examine an extensive collection of *cones*, particularly if it contain many individuals of each species, for the purpose of comparison, without being struck by the force of the observation. Colour, granulation, or smoothness, length or shortness of the spire, its plainness or coronation, will be found in many species the result of locality, food, or temperature.' M. Duclos, in reference to the numbers given by Lamarck, states, that he is convinced that there are many of the species which can only be regarded as varieties at most.

Many of these species and varieties are very beautiful, both in shape and colour, and the genus has always been highly valued by collectors. *Coni*, *gloria-maris*, *cedo-nulli*, *omaicus*, *aurisiacus*, *ammiralis*, and some others, have brought very large prices, and some of the finest specimens of these shells are now in this country.

Lamarck separates the genus into two divisions: the first comprising those species whose spire is coronated; and the second those whose spire is simple. By far the greater proportion of species belong to the latter division.

De Blainville thus divides the genus.

α.

Conical species with a projecting spire, which is not crowned with tubercles. (Example, *Conus generalis.*)

β.

(Genus Rhombus, De Montfort.)

Conical species with a coronated spire, which is either projecting or flattened. (Example, *C. imperialis.*)

γ.

(Genus Cylinder, De Montfort.)

Species a little elongated, suboval; the spire projecting and pointed, but not coronated. (Example, *C. textile.*)

δ.

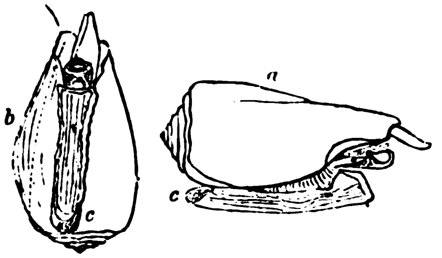
(Genus Rollus, De Montfort.)

Subcylindrical species, the spire apparent and coronated. (Example, *C. geographus.*)

ε.

(Genus Hermes, De Montfort.)

Elongated, cylindrical species with a projecting spire, and the aperture as in the genus *Terebellum*, that is, angular posteriorly. (Examples, *C. Nussatella* and *C. mitratus.*)



[Animal of Conus bandanus.]
a, seen in profile; *b*, view of under side; *c*, operculum.

Mr. G. B. Sowerby ('Genera of Recent and Fossil Shells') observes, that the *cones* are liable to be confounded with the *Pleurotomata*, and the young specimens of some *Strombi*; and those which are rather ventricose with young *Cypræœ*; but that they may be distinguished from the *Pleurotomata* by their short spire, their linear aperture, and their straight columella; from the young *Strombi*, by their being entirely destitute of varicose sutures, and by their never having any appearance of a notch near the lower extremity of the outer lip; the young *Strombi* moreover are seldom, if ever, so regularly conical; and from the young *Cypræœ* by the thickness of their shell, by the coronated or abrupt spire, and by their not being naturally polished in every part, which the *Cypræœ* always are, in consequence of the want of epidermis which covers the shell of the *cone*, while in the *Cypræœ* the large mantle comes in contact with the whole of the shell.

[Shell of Conus generalis.]

Fossil Conidæ.

Lamarck records nine fossil species. Deshayes in his Tables makes the number 49 (tertiary), one of which, *C. Mediterraneus*, he gives as both living and fossil (tertiary). Mr. G. B. Sowerby ('Genera') says, 'Fossil cones are not unfrequent; but we believe that they occur only in the newer strata, or those above the chalk, such as the London clay and crag in England, the calcaire grossier in France, and the contemporaneous beds in other countries: there are a few seen in collections, filled with a coarse, dark-green arenaceous substance; these belong to the *Terrains calcareo-trappéens* of Brongniart. Doubtful casts are met with in the inferior oolite, according to Conybeare and Phillips.' The same author gives a figure of *C. dormitor*, a fossil from Barton, approaching very near to a *Pleurotoma*. Many species are found in the blue marls of the south of France. (M. Marcel de Serres.) M. de Basterot gives many from Bordeaux and Dax, &c., one of them, *C. deperditus* of Lamarck, as analogous to the existing species at Owhyhee. Among the fossil species from the western borders of the Red Sea, collected by Mr. James Burton, named by Mr. Gray and Mr. Frembley, and communicated to Mr. Lyell by Mr. Greenough, are twelve species all living; but neither *C. Mediterraneus* nor *C. deperditus* appears in the list.

CONVENT, from the Latin *conventus*, an assembly or meeting together. This word is used in a double sense, first, for any corporation or community of religious, whether monks or nuns; and secondly, for the house, abbey, monastery, or nunnery in which such monks or nuns dwell. Shakspeare uses it in the first sense, when he says of Wolsey—

> 'At last, with easy roads, he came to Leicester,
> Lodged in the abbey; where the reverend abbot
> With all his convent honourably received him.'
> Hen. VIII., act iv., sc. 2.

Addison uses it for the building:—'One seldom finds in Italy a spot of ground more agreeable than ordinary that is not covered with a convent.'

Furetiere, who wrote his dictionary in the time of Louis XIV., says there were no fewer than 14,000 convents formerly in France.

Convent, as related to the foreign military orders, meant the principal seat or head of the order. Furetiere says, 'La Commanderie de Boisy, près d'Orleans, est le Convent général de l'Ordre de St. Lazare.'

The earliest inhabitants of convents were termed Cænobites, from the Greek words κοινός and βίος, as living in community. They dwelt chiefly in Egypt. Fleury (*Hist. Eccles.*, 4to., Paris, 1720, tom. v., p. 14) dates their institution as early as the days of the Apostles; others, probably with more correctness, give them a later origin. St. Pachomius, abbot of Tabenna, on the banks of the Nile, who was born at the close of the third century, is believed to have been the first person who drew up a rule for the Cænobites. (Moreri, *Dict. Histor.*, tom. viii.)

CONVENTION, MILITARY, a treaty made between the commanders of two opposing armies concerning the terms on which a temporary cessation of hostilities shall take place between them. It is usually solicited by that general who has suffered a defeat, when his retreat is not secure and small chance is left of maintaining his position; and it is seldom refused by the victor, since, without incurring the unavoidable loss attending an action, his force becomes immediately disposable for other operations.

In 1757 the duke of Cumberland, when in danger of being surrounded, entered into a convention with the duke de Richelieu, through the medium of Denmark, by which, on consenting to disband all his auxiliaries, he was allowed to retire with the English troops across the Elbe. And in 1799, when the Anglo-Russian army failed in the attempt to deliver Holland from the French power, the duke of York made a treaty with General Brune by which the invading force was allowed to re-embark on condition that 8000 French and Dutch prisoners of war in England should be restored.

After the battle of Vimiero in 1808, the duke of Abrantes, having been defeated, and fearing a general rising in Lisbon against him, sent General Kellerman to the quarters of the British commander-in-chief, to request a cessation of arms, and propose a convention by which the French troops might be allowed to retire from Portugal. This being granted, it was finally arranged in the convention that they should not be considered as prisoners of war; and that, with their property, public and private, their guns, and cavalry horses, they should be transported to France: on the other hand, all the fortresses which had not capitulated were to be given up to the British, and a Russian fleet, then in the Tagus was to be detained in English ports till after the conclusion of a peace. This is the celebrated convention which was made at Lisbon, and is generally but improperly called 'of Cintra.' It excited much dissatisfaction both in Portugal and England, as the cupidity of the French induced them to appropriate to themselves property to which they had no claim. (Napier, vol. i.). By the appointment of a committee consisting of one individual of each of the three nations, all causes of complaint were, however, finally removed.

CONVERGENT, CONVERGENCY, DIVERGENT, DIVERGENCY. When a series of numbers proceeding without end, has terms which diminish in such a manner that no number whatsoever of them added together will be as great as a certain given number, the series is called convergent. But when such a number can be added together as will surpass any given number however great, the series is called divergent. Thus of the two following series—

$$1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+, \&c., \quad \text{and } 1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\&c.,$$

the first is convergent, for no number of its terms, however great, will amount to 2: the second is divergent, and the sum of its terms may be made to exceed any number. By going a mile, then half a mile, then a quarter of a mile, &c., two miles could never be completed: but by going a mile, then half a mile, then one third of a mile, &c., a hundred million of miles, or any greater number, could be surpassed.

The subject of the convergency of series is one of fundamental importance in the whole of the mathematics; but it is seldom treated in works on algebra in the manner which its importance requires. Algebraical writers seem to have imagined that a series, however obtained, is safe and fit for use, whether convergent or divergent. If this be true, which, in a sense understood by writers on the higher part of the subject, we do not altogether deny, it is certainly not true to the beginner, without a great deal more of demonstration than is usually given. Considering the paucity of information which exists in our works on algebra, we shall state, rather more fully than usual, the results of investigation on the subject, together with the references to sources of information.

1. Series of increasing terms are certainly divergent.

2. Series of decreasing positive terms are divergent, unless the terms diminish without limit.

3. Of series of positive terms which diminish without limit, a test of convergency or divergency may frequently be given as follows. Let a, b, c, d, e, &c., be the terms of the series: form the new series

$$\frac{b}{a}, \frac{c}{b}, \frac{d}{c}, \frac{e}{d}, \frac{f}{e}, \&c. \quad \ldots\ldots \quad (A);$$

then if there ever arrive a term of the series (A), from and after which all the terms are not only less than unity, but tend towards a limit which is less than unity, the series is certainly convergent: but if the terms aforesaid become greater than unity, and continue so from and after a given term, the series is certainly divergent: and if the limit in the first case be not less than unity, but unity itself, the series may be either convergent or divergent, and each particular case must be examined by itself. Instances of both sorts can be given; and we know of no general rule for distinguishing between them, except the following, which includes all the cases we have seen, though we do not give it as a demonstrated test. Let the nth term of the series be N; and find a such that n^a N shall have a finite limit when n increases without limit. Then if a be greater than unity, the series is convergent; if equal to, or less than unity, it is divergent.

4. Series of the form $a + bx + cx^2 + dx^3 + ex^4 + \&c.$, can always be made convergent by giving a sufficiently small value to x, except only in the case where the terms in the series (A) increase without limit from and after any term. If they do not increase without limit, let L be the limit; then the preceding series is convergent whenever Lx is less than unity, is referable to the preceding case when Lx is equal to unity, and divergent when Lx is greater than unity. But if $L = 0$, the preceding is always convergent.

5. Series whose terms are alternately positive and negative, are always convergent when the terms diminish without limit, and the error committed by taking any number of terms to stand for the whole value, is never so great as the first term thus rejected. For instance, if the answer to a question be $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\&c.$, then 1 is not wrong by $\frac{1}{2}$, $1-\frac{1}{2}$ is not wrong by $\frac{1}{3}$, $1-\frac{1}{2}+\frac{1}{3}$ is not wrong by $\frac{1}{4}$, and so on. The results are alternately too great and too small.

6. When such a series as the last has its terms not diminishing without limit, but towards a finite limit, the sum of any number of terms, increased by half the limit, is never wrong by so much as the first-rejected term differs from the limit.

7. When series produced by algebraical development have their terms alternately positive and negative, the error committed by stopping at any term is never so great as the first rejected term, even though the series become afterwards one of continually increasing terms. If then such a series have the first few terms rapidly diminishing, a close approximation may be made by means of them to the real value of the expanded function. For instance, in the series $1 - 2x + 2.3x^2 - 2.3.4x^3 + \ldots.$ (in which an attempt to calculate from the whole series would be utterly futile, since however small x may be, there must be terms of every degree of magnitude) when x is small, an approximation may be made to its value from the terms which decrease. Thus if $x = \cdot 1$, in which case the series is

$$1 - \cdot 2 + \cdot 06 - \cdot 024 + \cdot 0120 - \cdot 00720 + \&c.,$$

(and the first term which surpasses that preceding, is $2.3. \ldots. 11\, x^{10}$): the aggregate of the terms up to $2.3 \ldots. 9x^8$ inclusive, will not differ from the true value of the expression by so much as $2.3 \ldots. 10x^9$ or $\cdot 0036288$. The proof of this curious proposition may be deduced from Lagrange's Theorem on the Limits of Taylor's Series. (*Lib. Usef. Knowl.*, Differential Calculus, page 73.)

Series which are functions of x, may be divided into—1. Those which are sometimes convergent, and sometimes divergent, such as the development of $(1 + x)^n$; 2. those which are always convergent at last, but in which the appearance of divergency (increasing terms) may be continued as long as we please, such as the development of ϵ^x; 3. series which are always divergent, but to which a similar appearance of convergency can be given, such as $1 + 2x + 2.3x^2 + \ldots.$, and the like; 4. Series which are always convergent or always divergent, and never can be made to exhibit any symptom of approach to the other state, such as

$$x+\frac{1}{x}+\left(x^2+\frac{1}{x^2}\right)+\ldots \quad \text{and} \quad \frac{x}{1+x^2}+\frac{x^2}{1+x^4}+\ldots$$

The series which are always convergent, both in reality and appearance, and upon which, therefore, an arithmetical algebraist would reckon with most security, do, in fact, offer difficulties of a very peculiar character. They are the only ones in which the usual algebraical generalizations would lead to absolute error (so far as has yet appeared). On this subject generally, see Peacock's 'Algebra,' and 'Report on Analysis,' (*Rep. Brit. Assoc.*, vol. ii.); Cauchy, 'Cours d'Analyse;' Grunert, 'Supplemente zu Klugel's Wörterbuche der Reinen Mathematik,' in the article Convergenz der Reihen; 'Encyc. Metrop.,' article Calculus of Functions.'

CONVERSE, in logic and mathematics, means a proposition which is formed from another by interchanging the subject and predicate, thus· the converse of 'Every A is B' is 'Every B is A.' But care must be taken to put the proposition in its simplest logical form before conversion. Thus the converse of 'Every A has a B' is not 'Every B has an A.' For the proposition first stated is

$$\text{Every}\begin{bmatrix}\text{A}\\ \textit{subject}\end{bmatrix}\begin{bmatrix}\text{is}\\ \textit{copula}\end{bmatrix}\begin{bmatrix}\text{a thing which has a B}\\ \textit{predicate.}\end{bmatrix}$$

and the converse is 'Every thing which has a B is an A.'

Of the four forms to which all assertions can be reduced, namely (A) 'Every A is B'; (E) 'no A is B'; (I) 'some As are Bs'; (O) 'some As are not Bs', the logical converses (so called) are those in which the new subject appears with the same degree of generality of assertion as the old one. Thus the converse of 'Every A is B', is '*Every* B is A.' Consequently in the first and fourth forms, or the general affirmative and the particular negative, the logical converse is not necessarily true. Thus 'Every A is B,' does not give 'Every B is A' *necessarily*, but only 'some Bs are As'. The latter is called by writers on logic conversion *per accidens*, a term which, as Dr. Wallis has declined to explain it, we shall leave as we find it, adopting the phrase diminished or limited conversion, and calling the first kind simple conversion. The only other method of conversion which has a definite name is that in which the subject and predicate are made contradictory to the former ones, as when we convert the proposition, 'All equilateral triangles are equiangular triangles,' into 'All triangles not equiangular are triangles not equilateral.' This is called conversion by contra-position. Restricting ourselves to converses which are necessarily as true as the direct propositions, we have the following rules with respect to A, E, I, and O above.

E and I are simply convertible.
E and A are convertible by diminution.
A and O are convertible by contra-position.

Nothing is more apt to make a beginner believe that 'Every A is B' yields 'Every B is A,' than the study of geometry without close attention to the meaning of terms and the force of the parts of an assertion. For as a majority of the earlier propositions have their simple converses true, the student does not sufficiently reflect upon this being contingent and not necessary.

In mathematical propositions there is a species of conversion which has no name, consisting in the interchange of the predicate with a part only of the subject. Thus if P, Q, R, and S be four circumstances, of which the existence of any three makes the fourth also exist, we may observe this species of conversion in passing from the first to the second of the following propositions:—

Every (thing which gives P, Q, and R) is (a thing which gives S).

Every (thing which gives P, Q, and S) is (a thing which gives R).

Thus of the following set of circumstances: 1. That two figures be parallelograms; 2. That they be equiangular; 3. That the sides about equal angles be reciprocally proportional; 4. That the areas be equal: exhibit the possibility of this conversion. For (1) (2) and (3) give (4); (1) (2) and (4) give (3); (1) (3) and (4) give (2).

There is an important logical proposition which would save some theorems in Euclid, and give a much clearer view of some of the arguments. It is evidently most desirable, when a proposition is a purely verbal and logical consequence of another, that it should be known to be such, and its proof distinguished from those which do *not* merely develop implied propositions.

Suppose, for instance, that a certain thing must be either an A, a B, or a C, but cannot be two of them; and that each, A, B, and C, must be either a P, a Q, or an R, but cannot be two. Suppose also that each P, Q, or R, must either be A, B, or C. If then it can be proved that every A is P (and not Q or R) every B is Q, &c., and every C is R, &c. the simple converses necessarily follow; namely, that every P is A, every Q is B, and every R is C. These converses are usually proved in Euclid by a *reductio ad absurdum*. [ABSURDUM, REDUCTIO AD.] For instances see book i. prop. 19, 25.

The proof of the converse is generally in Euclid a *reductio ad absurdum*. The necessity for this undoubtedly arises from the restrictions of geometry. [EUCLID.] If it were permitted to turn a triangle round till it recovers its first plane again, and then to compare it with the original triangle, the indirect demonstrations of the first book would be avoided for the most part. It seems a fanciful distinction to allow a triangle to revolve in its own plane, as in book i., prop. 4, and to refuse to admit revolution about a line in the plane. The subject of converses is discussed by Aristotle, 'Analytic. Prior.,' i. cap. 2, &c. See the editions of the 'Organon,' by Pacius, 1597, &c.

CONVEX. [CONCAVE.]

CONVEYANCE (in Law) is a deed or instrument in writing which passes real or personal property. The only conveyances used in the earlier periods of English history seem to have been feoffments and grants, though leases were soon used to pass a limited interest. The possession of land, as well as property of a movable nature, passed by tradition or actual transfer. The possession of land was given symbolically, by the delivery of a twig, a turf, &c., the charter of feoffment being the evidence merely of the transaction, and not essential to its validity. Hence, in the charter of feoffment, the operative words, or those which expressed the gift or transfer of the property, were used in the past tense, *hath given*, &c.: these terms are still used by some practitioners, although the reason for them has long since passed away.

A grant was applied to the conveyance of incorporeal hereditaments which did not admit of actual delivery into possession. From this difference in their application, a diversity was supposed to exist in the innate qualities of the two modes of conveyance, the feoffment being used to convey the actual possession of land, and operating upon the possession without any regard to the estate or interest of the feoffor; the grant to transfer the right of the grantor to the grantee: the former is frequently defined as a tortious, the latter a rightful conveyance. This definition however does not appear to be correct, and the tortious operation of a feoffment has been controlled and even denied in several recent decisions, Sir James Mansfield (in Goodright *v.* Forrester, 1 Taunt. 613) observing, 'Our ancestors got into very odd notions on these subjects, and were induced by particular causes to make estates grow out of wrongful acts.'

Sir William Blackstone distinguishes conveyances as original or primary, which are those by means of which the benefit or estate is created, or first arises; and derivative or secondary, whereby the benefit or estate originally created is enlarged, restrained, transferred, or extinguished. This division however is of little practical importance. Conveyances operate either according to the rules of the common law, or under the statute of uses; and in the case of a lease and re-lease, in both modes: and this latter is the most usual modern mode of conveying land and hereditaments. Conveyances may be further divided into those made by matter of record and by deed. As examples of those by matter of record, we may mention private acts of parliament, and the king's grant; and, until those modes were abolished by the recent statute 3 and 4 Will. IV., c. 74, fine and recovery. Those by deed are by feoffment, grant, bargain, and sale, covenant to stand seised, lease, release or confirmation, exchange, surrender. Conveyances simply transferring personal property are called assignments.

By the statute 13 Eliz., c. 5, voluntary or fraudulent conveyances of real property are rendered void, as against the creditors of the party making the transfer; and the 27th Eliz., c. 4, extends similar, and in some instances more extensive, relief to subsequent purchasers of the same property, although they may have had notice of the prior conveyance. The bankrupt and insolvent laws also provide for the relief of creditors against certain conveyances of real and personal property in derogation of their claims, or made within a specified time previous to the bankruptcy or insolvency.

In the session of 1836 a bill was introduced into the House of Lords by Lord Lyndhurst to simplify the conveyance of real property, but it did not pass into a law. Its object was to abolish the use of the lease in conveyances by lease and release. In Ireland a somewhat similar but less effectual provision was made by the Irish statutes, 9 Geo. II., c. 3, sec. 6, made perpetual by the 1 Geo. III., c. 3, which enacted that the recital of the lease should in all cases be sufficient evidence of it.

In many of the states of North America a simple bargain and sale is the usual mode of conveying real property. In New York it is called a grant; and the conveyance by feoffment and livery of seisin, and also the statute of uses, are expressly abolished by the legislature.

Conveyances in Scotland are made according to the strict principles of the feudal law there established, which imparts to them the appearance of far greater specialty and quaintness than those used in modern English practice. (Bl. *Comm.;* Butl. *Co. Litt.;* Kent's *Comm.*)

CONVEYANCING is the business of preparing conveyances of real or personal property, of investigating the title of the vendors and purchasers of property, and of framing those multifarious deeds and contracts which govern and define the rights and liabilities of families and individuals. It is carried on by barristers, or members of the Inns of Court, who having kept twelve terms, obtain a certificate according to the provisions of the 9 Geo. IV., c. 49, and are called Certificated Conveyancers. The increased number of transactions in this branch of the law has rendered a division of labour, and a special course of study, necessary.

There are two opposite systems, by which the transfers and transactions of the owners of real property are capable of being carried on; and between the extreme points of which, in some portion or other of the intermediate ground, all existing systems must arrange themselves. In one of these systems, as in the present system of England, every transaction is accomplished and evidenced by means of instruments in writing, varying infinitely, and governed by a scientific and ascertained mode of construction. In the other, the effect is accomplished somewhat like the transfer of stock, by a comparatively mechanical operation, a process of book-keeping, of which the evidence is to be kept, not in private muniments, but in the ledger-books or registers of the State.

The respective objects of these systems are, in the one, to protect the rightful owner, in the other, the innocent purchaser. In the latter the State takes upon itself the duty of seeing to the title of the owner whom it admits to registration, and consequently takes upon itself the risk of being deceived; in the former, it leaves the parties to concert titles and transfers in secret and in silence, leaves them unrestrained and unchecked to transact with one another, but compensates this want of interference by the alternative of following the right, by its judicial machinery, against all parties, however ignorant, however innocent, who may have had the misfortune, at any time subsequent to a defective transaction, or wrongful succession, to become the owners or purchasers of the property; limiting that restoration or succession only by reference to certain durations of adverse possession. (Parke's *Lect.*)

In the time of the feudal law, and the period immediately succeeding, restraint was placed on every species of alienation; landed property was rarely the subject of barter. Every transfer of land took place in open court, that is, on the land itself *coram paribus* (before the pars or peers), who were the other tenants of the feudal lord, and who subscribed the instrument of investiture as witnesses (Sulliv. *Lect.*, p. 58); so that, in the words of Lord Mansfield, it was as notorious who was feudal tenant *de facto*, as who is now *de facto* incumbent of a living, or mayor of a corporation. Land was 'of a stubborn nature,' money portions were unknown, and personal property did not exist in sufficient quantities to be made the subject of settlement, and consequently conveyancing transactions were few and simple. But the devices of the ecclesiastics to evade the statutes of mortmain, the invention of uses and trusts, and subsequently the passing of the statutes of uses and wills, which enabled the possessor of land to provide for the contingencies which might occur in his family, and to mould his estate according to his whim or fancy, controlled only by the laws from time to time established to guard against the abuse of the privilege, the power of devising real estate, and the multifarious wants of a large and wealthy population, laid the foundation of the system of modern conveyancing. 'By means of this system,' says a late eminent professor, 'there is no device, arrangement, settlement, or disposition which imagination [illegible] conceive, or ingenuity construct, which the machinery of the law of England cannot carry into effect with certainty. There is no conceivable purpose to which property may not be applied or rendered instrumental, no event, or combination of events, which can possibly happen in a family, of whatever rank or number, which may not be provided for and met, by a family settlement framed by a master of his art.'

Modern conveyancing is conducted on principles which in general are well defined and accurately settled. Of this a remarkable proof was afforded by a statement in Mr. Parke's 'Contre-Projet to the Humphreysian Code,' p. 199, upon the authority of Mr. Preston, that of the cases which came before him (averaging thirty a week), three per cent. only went on to judicial litigation.

The great endeavour, from the earliest times, on the part of the owners of property, has been to be enabled to effect sales and dispositions with secrecy and dispatch, without incurring that publicity which it was the policy of the common law to enforce. Whether it be desirable, for the sake of mercantile credit, to favour secrecy, or promote publicity, in the sale and disposition of property, has been lately much discussed: a general registry has been proposed, and a bill for establishing it thrown out of the House of Commons. [REGISTRATION.]

CONVICTION. [JUSTICE OF THE PEACE.]

CONVOCATION, the assembly of the clergy in form of parliament under the authority of the king's writ, which takes place at the commencement of every new parliament. The tendency of the western states of modern Europe in political relations to become thrown into the form of which king, lords, and commons is no inapt type, is apparent in the ecclesiastical constitution of almost every country in which Christianity has been received and professed. The archbishop has had his suffragan bishops, and the bishops each his canons, who formed his council, in some of whom have been vested peculiar functions, as dean, archdeacon, and the like; while the great body of the clergy have had their meetings under the form of diocesan synods or provincial assemblies, in which they have been accustomed to discuss matters pertaining to the common interest and benefit of themselves or of the whole church. [BISHOP, CANON, CHURCH, CLERGY.]

These meetings, resembling as they do in some points the convocation of the English clergy in later times, might easily be supposed to be that assembly in its primordial state. But writers on this subject trace out the origin of the convocation in something more special than this. It is supposed that originally the clergy were thus called together by the king's authority for the purpose of assessing themselves in levies of taxes at a time when they contended for exemption from the general taxation of the country imposed by the authority of parliament. Like many other questions in our early constitutional history (we mean by 'early' when we ascend beyond the reign of King Edward the First), this is perhaps one of presumption and probability rather than of evidence and certainty. Such, however, the convocation is generally understood to have been in the reign of King Edward the First, rather than an assembly of ecclesiastics summoned to consult on things pertaining to the church, as the purity of its doctrine, the regularity of its ordinances, and the influence of its teachings and administrations.

When such an assembly was called together under the supreme authority of the state, it was natural that such subjects should be introduced, discussed, and in some instances determined by it; and even now, though the convocation may be said to exist rather in name than in reality, it seems to form the proper constitutional assembly in which to legislate on such subjects, whenever legislation upon them is needed.

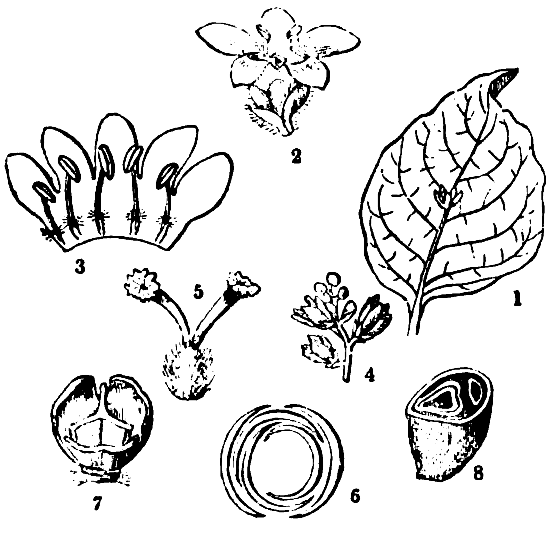
The crown, however, had always in its hands the power of controlling this assembly, possessing as it did the prerogative of proroguing and dissolving. But at the Reformation an act was passed (25 Henry VIII., c. 19,) which expressly deprived the convocation of the power of performing any act which could make such an assembly dangerous to the public. It was restricted by it from making any canon or ordinance which was opposed to the king's prerogative, or to the laws, customs, and statutes of the realm.

Again, in 1665, the clergy gave up the power of taxing themselves, consenting to fall within the scope of the statutes made in parliament for such purposes, like the laity, when they received a right of voting with the laity in the election of knights of the shire.

But though virtually the convocation thus became almost a nullity, yet the practice has been continued, and continues to the present day, of summoning the clergy to meet in convocation whenever a new parliament is called; and the forms of election are gone through in the dioceses, and the meeting is held, usually in St. Paul's Church, when the form is gone through of electing a prolocutor or speaker. The king's writ is directed to the archbishops, commanding them to summon the bishops and the inferior clergy. The archbishop complies with this writ, summoning the bishops, and commanding them to summon the archdeacons and deans in their respective dioceses, and to command the chapters to elect one proctor each, and the great body of the clergy in each diocese two proctors, to represent them in the convocation. When assembled, they form two houses. In the upper house sit the bishops; in the lower, the other clergy, in all 143; viz., 22 deans, 53 archdeacons, 24 canons, and 44 proctors of the inferior clergy. It is the usual practice for the king to prorogue the meeting when it is about to proceed to any business.

CONVOLVULA'CEÆ, a natural order of monopetalous exogens, with bell-shaped flowers, opening or contracting beneath the influence of light, a plaited æstivation of the corolla, five stamens, and a fruit with two or three cells, in which one or two ovules stand erect. The embryo is crumpled up in the midst of very firm albumen. The common bind-weeds of the hedges, the Ipomœas and Convolvuli of the gardens, offer illustrations of the ordinary state of this order, the species of which have purgative roots, and in the case of scammony, yielded by Convolvulus Scammonia, and of jalap, produced by various species of Ipomœa, are of great medicinal importance. Occasionally the purgative principle is so much diffused among the fæcula of the root as to be almost inappreciable, as is the case in the Convolvulus Batatas, or sweet potato of America, which was the forerunner of the common potato, and gave it its name, and which is still cultivated in the south of Spain and France.

In most instances the stems of this natural order are twining, and in such cases it is immediately recognized; but occasionally they are erect and more spiny, and when that happens it is not so easy to know the order. If however attention is paid to the very imbricated state of the calyx, two of the sepals being quite exterior with respect to the other three, no real difficulty in identifying it need be experienced. For illustration we have taken a singular East Indian genus called Neuropeltis, in which the flowers grow from the midrib of the bracteal leaves: it would be superfluous to figure a bind-weed.



1, a bracteal leaf of Neuropeltis racemosa, with a flower growing from its midrib; 2, one of its flowers magnified; 3, a corolla opened, showing the stamens; 4, a small cluster of flowers; 5, one of its ovaries with two styles; 6, a section of the calyx of a Convolvulus; 7, half a capsule, with valves separating by their edge from the dissepiments; 8, a transverse section of a seed, showing a part of the embryo lying in the albumen.

CONVO'LVULUS, the genus of plants upon which the natural order Convolvulaceæ is founded, is known by its style being divided into two linear arms, and its ovary having only two cells, in each of which stand two erect ovules. Many of the species are exceedingly beautiful; even C. arvensis, the common bind-weed, would be prized as a lovely flower, if it were not so common, and such a troublesome plant to eradicate on account of its creeping roots. C. althæoides, italicus, and scammonia are the three prettiest of the hardy exotic species of the genus.

CONVO'LVULUS JALAPPA, and **C. SCAMMONIA**. The resins of the Convolvulaceæ, upon which these and other species depend for their activity as medicines, appear to be of two distinct kinds; the one soluble in proof spirit and insoluble in æther (found in jalap, turbith, and bind-weed), the other soluble both in alcohol and æther (found in scammony and C. soldanella). Jalap is chiefly shipped from Vera Cruz, and takes its name from the town of Xalapa, or Jalapa, in the interior. It is best when collected in March or April, before the young shoots have begun to be developed. The large root, which often weighs 50 pounds, is divided into portions, which are hung in nets over a fire, and dried in ten or twelve days. It occurs in commerce in irregular round or pear-shaped masses, which, when good, are dry, hard, with a brown shining fracture, resinous, not light, somewhat tough. It is often adulterated with portions of the root of white bryony, which however are white, or when old, gray, not heavy, very brittle, fracture not resinous, spongy, without smell, but with very bitter taste. Dried pears are also often substituted for it; but they may be detected by being laid open, when the core will be seen, containing the seeds. Analysed by Cadet de Gassicourt, 100 parts of the dry root yielded resin 10, gummy extractive 44, woody fibre 29, starch, albumen, salts of lime, and potass, &c. Its excellence depends upon the quantity of resin; a white jalap (from C. Mechoacanna) is sometimes met with, which contains only 2 per cent. of resin; its dose must be five or six times as great as that of the genuine jalap.

Jalap is ranged with the drastic purgatives, and where one of a resinous kind is desired, is that usually selected. Its action is generally certain, and when in combination with other substances, mild and speedy. It does not seem greatly to influence the nerves of the abdomen, but rather the vascular system of the pelvis and lymphatic system of the intestines. It is given in obstruction of the liver, vena porta, and diseases connected with these organs, such as hypochondriasis, melancholia, jaundice, dropsy, and intermittent fevers; but at the commencement of common fevers, along with calomel, it is of great utility; also in the inflammatory or turgescent stage of hydrocephalus, and in the treatment of worm cases.

Scammony is of the same nature as jalap, but being the inspissated juice obtained by making incisions into the living root, it consists of a much larger proportion of resin, without any woody fibre. It is therefore much more powerful, and the dose requires much less than that of jalap. Three kinds are met with: the best from Aleppo contains 60 per cent. of resin, with 35 per cent. of impurities; second sort from Smyrna, contains only 29 per cent. of resin and 58 of impurities; the third sort, from Antioch, is very bad. In France a so-called scammony, obtained from the Cynanchum monspeliacum, is very bad, and dangerous to employ. Scammony is used in nearly the same cases as jalap, and the smaller bulk of the dose renders it in many instances preferable: it often sits better on the stomach; no medicine surpasses it in clearing away the mucous accumulations in the bowels of children, which harbour, if they do not generate, worms. It should not, however, be too frequently repeated, as its power in this respect renders it a source of danger, by abrading the inner coat of the intestines of its necessary mucous covering, and thereby causing it to become inflamed. [CATHARTICS.]

CONVOY, in the military service, is a detachment of troops appointed to guard supplies of money, ammunition, provisions, &c., while being conveyed to a distant town, or to an army in the field, through a country in which such supplies might be carried off by the peasantry or by parties of the enemy.

In the navy, the name is applied to one or more ships of war which are ordered to protect a fleet of merchant-vessels on their voyage.

CONVULSIONS, irregular (anormal) and violent contractions of muscular fibres with alternate relaxations. The muscles of the body are divided into two great classes, those which produce the motions necessary for the due exercise of the organic functions, and those which produce the motions necessary for the performance of one of the animal functions, namely locomotion. The first division comprehends the class of the involuntary, and the second that of the voluntary muscles. Contractility, the property of shortening itself on the application of a stimulus, is the proper function of the muscular fibre,; and by this property all vital motion of every kind which takes place in the living system is performed. [Muscle.]

The property of contractility is inherent in the muscle; but the manifestation of this property is wholly dependent on the nervous influence; for if the nervous influence be abstracted from a muscle, its fibres are incapable of contracting, whatever degree of stimulus be applied to them. When the muscular fibre is in a sound state, and is supplied with the nervous influence in proper quantity and of proper quality, the fibre contracts with a given degree of force on the application of a certain amount of stimulus. This degree of contraction constitutes its regular or normal action. Contraction, after it has continued a certain time, is succeeded by relaxation; relaxation, in its turn, yields after a given time to another contraction; this contraction to relaxation, and so on successively according to the order proper to muscular action when natural and sound. [Muscle.]

But when, on the application of a given stimulus, the muscular contraction is either more violent or more rapid, or longer continued than natural, that is, when it does not yield in proper time to the alternate state of relaxation, the muscular action is said to be convulsive, and the disease termed convulsion is induced. The state of convulsion is also produced when the muscular fibre is excited to inordinate action on the application of a stimulus not natural to it. The function ultimately deranged in convulsion is the muscular contractility; but the function proximately deranged is the nervous influence; the manifestation of disease is in the muscular, but its true and proper seat is in the nervous system.

Both divisions of the muscular system, the voluntary and the involuntary, are subject to this irregular and violent action. When the muscles of animal life, or those of voluntary motion, are thus affected, it constitutes the disease called convulsion in its true and proper sense; when the muscles of organic life, or those of involuntary motion, are thus affected, the disease is usually termed spasm. This distinction is not indeed invariably and universally observed by medical writers; but it would be very convenient if it were so. When the muscle is rigid and tense, and its contraction is persistent, not quickly alternating with relaxation, the contraction or spasm is called tonic; when the contractions rapidly alternate with relaxations, the convulsion or spasm is called clonic. In the first, the vital energy of the muscle is in excess; in the second it is deficient. When the convulsive or spasmodic action is of the clonic kind, but instead of being violent is slight, and when very slight contractions rapidly alternate with relaxations, it constitutes what is called *tremor*.

Convulsions differ, first, in kind, as dependent on an excess or a deficiency of vital energy; secondly, in degree; varying from the most powerful, violent, and persistent contractions, without perceptible relaxations, or with relaxations of very short duration, down to the feeblest contractions, with the most rapid alternate relaxations of the slightest tremor; thirdly, in their seat, affecting either the voluntary or the involuntary muscles, or both simultaneously or in succession; fourthly, in their cause, arising from a primary affection of the nervous system, or from irritation propagated to the nervous system from some other part (primary or secondary); fifthly, in their extent; affecting one part separately, or nearly the whole frame simultaneously (local or general); and sixthly, in their character (simple or specific): simple, when unattended with phenomena which give them a determinate type, that is, when the phenomena consist merely of convulsive or spasmodic action; specific, when the convulsive actions pursue a regular and determinate course, and when, moreover, some particular phenomenon is superadded to the series constituting a distinct form or type of disease. In this latter case the disease receives a generic name. The term epilepsy, for example, is given to the disease when the convulsions come on in a peculiar mode, and pursue a determinate course, and when there is present the superadded phenomenon of insensibility or sopor. On the other hand, in the affection called hysteria, the convulsions come on in a different mode, pursue a different course, and are attended with a different but still a determinate train of morbid phenomena. In these cases convulsions forming the species of disease, the series of determinate morbid phenomena constitute so many different genera under it.

Voluntary muscles are far more frequently the seat of convulsions, properly so called, than the involuntary muscles. The diaphragm, indeed, an involuntary muscle, next in importance to the heart, is often affected with a proper convulsive action, constituting the disease called singultus or hiccup; and the heart itself appears to be occasionally affected with a proper convulsive action, in some of the forms of palpitation, for example; but in general, when the organs of the organic life, as the bronchi, the stomach, the intestines, the urinary bladder, the uterus, &c., are attacked with an affection of this kind, it is much more closely allied, as has been stated, to the nature of spasm than of convulsion.

Of the voluntary muscles, whether those appropriated to locomotion, or those destined to act on foreign bodies under the command of the will, and also of certain muscles which, though not under the direct command of the will, still belong to the animal life, having a close relation either to sensation or emotion, there is not one which may not be the seat of convulsion, singly, or conjointly with many others.

The muscles of the eyelids, the muscles that move the ball of the eye, the muscular fibres of the iris, the muscles of the face, and more especially of the lips, the muscles of the tongue, the muscles of the pharynx, the muscles of the jaws, and particularly of the lower jaw, the muscles of the neck, the muscles of the chest, back, and abdomen, and the muscles of the upper and lower extremities, may be severally attacked singly or in combination, simultaneously or in succession, with every degree of convulsion, from the most violent tonic contractions to the slightest clonic tremors or twitching. The particular muscles affected, the particular combinations of the muscles affected, the particular order in which the muscular affections succeed each other, may be indicative of specific diseases of the nervous system or of diseases seated in particular parts of the nervous system. The study of these convulsive affections is therefore most important in a practical point of view, as indicating, at one time, the near approach or the actual existence of highly dangerous diseases, having their primary seat in the brain or in the spinal cord; and at another time pointing to no less formidable diseases of the brain and spinal cord excited by diseases of some distant organ.

When convulsions attack a single muscle, or a particular set of muscles, the convulsions are called partial or local; when they attack a great number of muscles simultaneously or in rapid succession, they are called general.

The accession of convulsions, whether local or general, is commonly, though not invariably, preceded by premonitory signs. An attention to such premonitory signs, when present, as they will almost always be found to be, if carefully looked for, is of the last importance; because it may lead to the adoption of means which may prevent the attack. Among the most common and decisive premonitory signs of an approaching attack of convulsions may be enumerated, flushing of the face, or the opposite state, an unusual pallidness of the countenance; giddiness; noise in the ears; spectra floating before the eyes; sudden and transient loss of sight or of hearing; unusual drowsiness, or the contrary state of sleeplessness and restlessness; a sensation of coldness creeping down the back or pervading the limbs; sickness or nausea at the stomach; palpitation of the heart; hurried irregular respiration; tendency to sigh; a sensation of faintness; torpor or despondency of mind, and an unusual irritability of temper. It is rare, that some one or more of these or of other analogous signs do not give warning of the approach of the paroxysm. The presence of such signs should therefore not only not be neglected, but, wherever there is a predisposition to the disease, should be carefully looked for, that measures appropriate to the particular nature of the case may be promptly taken to prevent an occurrence of the attack.

In the actual paroxysm, the features of the face are sometimes hideously distorted; the eyeballs are prominent, staring, vacant, wild, and are rolled in every direction; the teeth gnash; the mouth foams; the tongue protrudes; and the action of inspiration from the passage of the air through the clenched teeth, is attended with a hissing sound. So violent are the contractions, that occasionally the teeth and sometimes even the bones of the extremities are broken by the force. When the muscles of respiration are involved, and the respiratory function is much obstructed, the face becomes tumid, bloated, and of a dusky or purple colour; and sometimes even the entire surface of the body assumes a leaden hue, from the obstructed circulation through the lungs and the imperfect aëration of the blood. Such is the obstacle to the progress of the blood, that the blood-vessels sometimes give way, and the blood bursts from the nose, or is effused extensively beneath the skin, the effusion probably preventing irreparable mischief to the brain. At other times the face, instead of being red, is pallid and sunk, and then the pulse is feeble, small, and contracted; as in the former case it is full and strong, and attended with a violent beating of the carotids. The violent contractions of the muscles act upon the bladder and rectum, and expel their contents involuntarily and with force. In all the cases in which the current of the blood is much obstructed, the functions of the brain are proportionally impaired, the general sensibility is diminished, and there is sopor, or even coma; at other times consciousness is but little affected, and the violence of the contractions produces severe pain.

The duration of the paroxysm varies from a few minutes to as many hours. The moment the convulsions subside, the patient commonly falls into a long and profound sleep, from which he awakes suddenly, altogether unconscious of what has happened. The attack is generally succeeded by languor, lasitude, sickness, and a disordered state of the stomach.

The paroxysm commonly returns at uncertain intervals, preceded by the premonitory symptoms just enumerated. But sometimes it proves fatal at the very first attack, by producing apoplexy or asphyxia; and not unfrequently it leaves behind it either paralysis or some definite and permanent form of convulsive disease, as epilepsy, chorea, and so on. The frequent recurrence of the fits invariably impairs, and sometimes wholly destroys, the mental faculties.

In some peculiarly nervous and irritable temperaments, instead of the languor and lassitude which ordinarily follow a severe convulsive paroxysm, the exhaustion is so extreme that the patient falls into a state of profound syncope or fainting, which continues for so long a period as justly to excite alarm; and sometimes the patient actually dies in this fainting fit, the brain never recovering its functions. At other times, when the animal life is completely suspended, and the action of the organic life appears to have ceased, but the latter is not wholly extinguished, though its functions are performed so feebly as to afford no indication of their existence; and consequently, to all outward appearance the patient is dead; yet he may be only in a state of lethargy or torpor, and may ultimately revive. It is in cases of this kind that there is a real danger of premature interment. Several cases are on record in which this event is stated to have actually happened, and the evidence on which the truth of some of these narratives rests it is difficult to resist. At all events it is quite certain, that several persons who had fallen into the state of syncope, after the exhaustion of convulsions, have narrowly escaped being buried alive; and such cases should make the medical attendant persevere in the most careful examination of every instance of apparent death, after a convulsive paroxysm, until he has observed the most unequivocal evidence that death is real.

The preceding account of a paroxysm of convulsion, is the description of it only as it exists in its severest form. In general even the tonic seizure is a much more mild attack; the convulsions being not violent; affecting only a few muscles at a time, and rather passing in succession from one set of muscles to another, than attacking a great number simultaneously. In general too the convulsions are unattended with the obstruction of respiration; are without the abolition of sensation; in short, are without the permanent and dangerous interruption of any function, organic or animal. And more especially when the paroxysm is of a clonic character, the muscles are not rigid, the contractions are not vehement and long-continued, the face is not swollen and livid, but rather pale and sunk, the features are little distorted, the pulse is feeble and rapid, and the extremities are cold.

Convulsions are frequently excited in the progress of other diseases, towards the termination of continued fevers, for example, in which they are almost always of bad, and sometimes of fatal omen; at the commencement of eruptive fevers, as small-pox, measles, scarlet fever, &c., when, though generally indicative of a severe form of disease, they are not so alarming as at the close of continued fever; in inflammatory affections of the brain; in hooping-cough; in cramp; in disordered states of the reproductive organs, and more especially of the uterus, and in long-continued suppression or imperfect performance of the catamenial function.

The causes of convulsions are exceedingly numerous and varied. There is, without doubt, a constitutional predisposition to such affections. They occur far more frequently in the nervous temperament than in any other. The distinctive character of the nervous temperament is muscular mobility combined with nervous irritability. The muscular fibre is relaxed, delicate, and weak; the nervous fibre is peculiarly sensitive, while it is proportionally without energy. Other powerful causes are, peculiar conformation of the body, namely, a feeble frame, with a largely-developed head; a relaxed and delicate fibre; a full and plethoric habit; a constitution often manifestly propagated from parent to child; all circumstances capable of producing over-excitement, or in any other mode of inducing debility, physical or mental; as an idle and luxurious mode of life; too much indulgence in sleep; neglect of regular and active exercise, and, as would appear, certain electrical conditions of the air, by which the nervous system is rendered more susceptible of impressions, and its vital energy is more rapidly exhausted.

The exciting causes are those which act either upon the animal or upon the organic portion of the nervous system. It has been stated that contractility, though a property inherent in the muscular fibre, can be excited only through the agency of a stimulus derived from the nervous system. All the muscles which are under the control of the will, or which depend on an act of volition for the exercise of their function, derive their nervous stimulus from a particular portion of the nervous system, namely, the spinal cord. Modern physiology has demonstrated that the nervous fibres which supply the stimulus necessary to voluntary muscular motion are different from the nervous fibres which communicate sensation. The first, the motive nerves, communicate with a particular portion of the spinal cord; the second, the sentient nerves, communicate with another portion of the spinal cord. Now, it is found that whatever disturbing influences act immediately upon the motive nerves, or upon that portion of the spinal cord with which the motive nerves are in direct communication, constitute most powerful exciting causes of convulsions. But there is so close a sympathy between the sentient and the motive portion of the spinal cord, and between the spinal cord and the brain, that any disturbing influence which acts powerfully on the one is rapidly communicated to the other. It is indeed seldom that it is possible to trace the seat of the irritating cause either to the motive or to the sensitive portion of the nervous system exclusively; that would imply an accuracy and completeness of knowledge which pathologists are at present far from possessing. All that the present state of knowledge almost ever admits of is to trace the seat of the irritating cause to some portion of the spinal cord or brain; and this, which is nearly all that can be done in any other case, is sufficient to connect the morbid condition of the organ with its disordered function. There are then morbid conditions of the spinal cord and brain which are clearly ascertained to be immediately connected with that disorder of their functions of which convulsions are the result.

Such are, 1. A disordered state of the circulation of the blood through these organs. One of the conditions the most essential to the due performance of the functions of the nervous system is, that the spinal cord and brain receive a certain supply of arterial blood. If the quantity of blood which flows to these organs be deficient, syncope will be induced, with a diminution or loss of muscular power: of this state convulsions, always of a clonic character, are a constant result. If the blood transmitted to the spinal cord and brain do not circulate through the blood-vessels with a certain impetus and velocity, but be retained either in the capillary arteries or veins, or in both, the state termed congestion [Congestion] will be induced, of which convulsions, also in general of a clonic character, are a constant result. If the blood sent to the spinal cord and brain be in preternatural quantity, and if it circulate with preternatural energy, the state of inflammation will be induced, of which convulsions, always of a tonic character, are a constant result. Whether, then, the balance of the circulation be disturbed by deficiency or excess in the quantity of the circulating blood, or deficiency or excess in the motion of it, it will prove alike an exciting cause of convulsions. 2. Precisely the same results are produced if there circulate through the blood-vessels blood vitiated in quality, blood too much venalized, or too much arterialized, or impregnated with poison. The characters of the convulsions induced by exciting causes of this class vary essentially according to the nature and extent of the vitiation of the blood and the kind of poison with which it may be imbued. 3. Extravasation of blood upon the surface or into the substance of the spinal cord and brain, by the rupture of the blood-vessels; or the effusion of the serous portion of the blood, occasioning direct pressure on the nervous matter. 4. Organic changes in the constitution of the nervous substance, as a preternatural softening or a preternatural hardening of it. 5. Morbid growths within the nervous substance, forming tumours of various natures and sizes. 6. Mechanical injury of the nervous substance, from the irritation occasioned by the deposition of bony matter on the investing membranes of the nervous substance, or from spiculæ of bone growing out from the inner table of the osseous cases that inclose it. 7. Mechanical violence directly applied to the nervous substance, as from a blow or fall, by which a shock, exhaustive of its vitality, may be communicated to it, or its substance injured or its circulation disturbed. Such are the more powerful exciting causes which act directly on the animal portion of the nervous system.

But convulsions may be equally induced by the action of an irritating cause on the organic portion of the nervous system. The irritation excited in the organic nerves is transmitted to the communicating branches of the spinal and cerebral nerves, and is by these communicating branches conveyed to the spinal cord or brain. It is in this manner that irritating substances in the stomach or in the intestines induce convulsions, as indigestible or acrid substances taken as food, or acrid matters generated or evolved during the digestive process, or retained by long-continued constipation [Constipation] in some part of the alimentary canal; or the accumulation of acid, or the presence of worms, &c. Many other noxious agents which act upon one or other of these nervous circles, or upon both conjointly, might be enumerated as the exciting causes of convulsions; but those which have been stated may suffice to indicate the kind of noxious agents which induce this affection, by disturbing the functions of the nervous system.

The treatment in every case of convulsion must be directed to the subduing of the paroxysm and to the prevention of its return. There are certain things proper to be done the instant a person is seized with a fit of convulsions, with a knowledge of which it is desirable that every one should be familiar. The patient should be immediately surrounded as completely as possible with fresh cool air. If he be seized in a small heated and crowded room, circumstances of themselves sufficient to produce a paroxysm in a person strongly predisposed to it, he should be removed into a spacious apartment, the windows of which should be thrown open, and every one whose assistance is not absolutely required should be excluded from the room. In the male, the neckcloth should be immediately untied, and the face, neck, and bosom freely exposed to the air; in the female, the stays should be unlaced, and every thing tight about the body should be removed. If the skin be cool and the face pallid and sunk, the patient should be placed in the horizontal posture; if the skin be hot and the face flushed, he should be sustained in the sitting or the erect posture, in order, in the former case, to favour the flow of blood to the spinal cord and brain; and in the latter, to retard it.

The remedies employed to put an end to the fit must of course depend on the nature of the exciting cause, and on the pathological condition of the nervous system. If the vascular action of the nervous system be highly excited; if the pulse be rapid, full, and strong; if the skin be hot, and the face flushed; if the eye be injected, wild, and glistening, means must be taken the very opposite to those which are proper when the circulation is depressed, the pulse rapid and feeble, the skin cool, the face pallid and sunk, and the eye dull, heavy, and expressionless. The experienced eye of the observing and discriminating practitioner will gather at a single glance, from the presence or absence of sopor, from the presence or absence of the signs, familiar to him, of active or passive congestion [Congestion], from the action of the carotid arteries, from the temperature of the skin, from the plethoric habit of the body, and from the character of the convulsions, almost all the information necessary to determine the first steps to be taken. Whether it be necessary to employ the lancet vigorously, opening a large orifice in the vein of both arms at once, or opening the jugular vein, or the temporal artery, or whether it be more desirable to have recourse to revulsive bleeding, by opening the veins of the feet, retaining the feet in warm water, or to employ topical depletion, by cupping behind the ears, at the nape of the neck, or between the shoulders; or whether the very opposite treatment be required, and life itself depend, as it sometimes does, on the administration of stimulants, restoratives, antispasmodics, opiates, he will be clearly taught by symptoms, which only perplex and confound the ignorant and the undiscerning. Not only the shortening of the paroxysm, but the preservation of life, will constantly depend on his perception of the right, among apparently opposite indications; on the promptness of his decision, and the energy of his action. There are few departments of medicine in which more care and skill are required to make the proper selection, and to adopt the most advantageous mode of exhibiting even the auxiliary remedies, namely, the application of cold and heat, the administration of purgative medicines; the application of counter-irritants, &c. If possible, a still higher demand will be made on professional knowledge and judgment, to detect the organs whose altered structure or diminished function are the cause of the disease, and to discriminate their exact pathological condition. Unless a sound conclusion be arrived at on these points, no rational course of treatment can be pursued, and it is more than probable that the very agents employed to cut short the paroxysm will increase the danger, and that the course adopted to prevent the return of the fit will facilitate and hasten its recurrence. It is impossible in this place to enter on a field of professional investigation so extensive and important; it is one on which the labours of modern pathologists have shed great light; and it is the duty of every medical practitioner diligently to study their works, that he may collect every scattered ray to guide him through a course in itself difficult and intricate, and in which, if he err, the consequence must always be mischievous and often fatal.

CONWY. [Caernarvonshire.]

COOCH BAHAR, a principality occupying the north-east extremity of the province of Bengal, and lying between 26° and 26° 30′ N. lat., and between 88° 52′ and 89° 52′ E. long. This principality, which once formed the western division of the antient kingdom of Camroop, has long been in a state of absolute dependence on the English government, to which an annual tribute is paid to the amount of half the revenue, and for the purpose of securing this tribute, the principality has been placed under the controul of the collector of the adjoining district, Rungpore. The extreme length of the principality from east to west is sixty miles, and its mean breadth about twenty-two miles, the total area being 1302 square miles.

The distinctive name, Cooch, has been given in order to mark the difference between this principality and the province of Bahar (described vol. iii., p. 276). This name, Cooch, is derived from that given to the majority of the inhabitants. The name of Cooch Bahar is displeasing to the chiefs of the country, who repudiate all connexion with the Cooch, and call themselves *Rajbangsies* (descendants of princes). Many of the Cooch tribes have relinquished the practices of their ancestors, which were characterized by various impurities, and have adopted the Brahminical faith; while others who inhabit the northern quarter of the principality, near to the frontier of Bootan, continue rude and barbarous in their habits. Their religion allows them to eat pork, mutton, venison, and poultry, but not beef; some of the more barbarous among the tribes not only eat beef, but frogs, cats, dogs, and snakes.

The southern parts of the principality are much improved by culture, and of considerable fertility; but in the north the country is low and marshy, and contains abundance of thick jungle. A considerable quantity of opium is produced, as well as indigo, and some cotton. Wheat is cultivated, and a little barley. Trade between the principality and the adjoining British territory is perfectly free, and the people have also commercial dealings with Asam and Bootan. Among the more indigent classes in the north, it is customary for the people to sell their children for slaves, although this traffic is much discountenanced by the English government.

The sovereign of this country is described in the Ayin Akbari as having been a powerful chief, at the head of an army of 1000 horse and 100,000 foot soldiers, and having Asam and the whole kingdom of Camroop under his sway, his territory being bounded on the east by the Bramahpootra river, on the south by Gorhaghaut, on the west by Tirhoot, and on the north by the Thibet mountains. This country was conquered by the Moguls about the year 1660, and subjected to an annual tribute of ten lacs of rupees. In 1772, when the East India Company had succeeded to the rights of the Mogul emperor, the rajah of Cooch Bahar applied to the collector of Rungpore for protection against the attacks of the Bootaners, by whom he had been reduced to great extremities. It was on this occasion that the rajah offered to pay an annual tribute to the English equal to one-half of his revenue, which offer being accepted, a British force was despatched to his assistance, and the Bootaners were made to retire precipitately. The tribute having fallen into arrear, and the internal affairs of the country being greatly disorganised, an English commissioner was appointed in 1789 to collect the revenues and controul the public expenditure, retaining the amount of the tribute, and paying over the surplus to the rajah. At this time the rajah was a minor, and when he attained his majority in 1801, the commissioner was withdrawn, but the right of superintendence was still retained in the hands of the collector of Rungpore. During the residence of the commissioner, the finances of the country were rescued from the state of disorder in which they were found, the tribute was regularly paid, and a considerable surplus accrued, which was invested for the benefit of the rajah in the English funds. No sooner however had the commissioner been withdrawn, than the old irregularities were again experienced, the tribute was obtained with great difficulty, and the rajah himself was kept in a state of poverty, while his ministers by a system of extortion and embezzlement were amassing fortunes. This state of affairs continued until 1813, when the tribute being withheld, and the country generally in a state of complete anarchy, a resident English commissioner was again appointed by the governor-general, the rajah was compelled to dismss his ministers, and appoint others on the nomination of the English government, and a system of criminal jurisprudence was established, and administered through the agency of the British commissioner. The amount of annual tribute paid to the Bengal government is between 60,000 and 70,000 rupees. (*Ayin-i-Akbari;* Rennell's *Memoir of a Map of Hindustan;* Mill's *History of British India.*)

COOK, CAPTAIN JAMES, was the son of an agricultural labourer and farm-bailiff, resident at Marton, six miles from Stockton-upon-Tees, in Yorkshire, and was born October 27, 1728. At an early age he was apprenticed to an haberdasher at the fishing town of Staiths, near Whitby. Here his genius soon showed its true bent; and having procured a discharge from his master, he apprenticed himself to a firm engaged in the coal trade at Whitby, in whose service he continued, rising gradually, till he attained the situation of mate. Being in the Thames in 1755, when men were greatly sought after, he resolved to take his chance as a volunteer in the royal navy. He was soon distinguished as a skilful and trustworthy seaman: and such effectual interest, backed by the favourable testimony of Captain, afterwards Sir Hugh Palliser, was made in his behalf at the Admiralty by some Yorkshire gentlemen, that in May, 1759, he was appointed master, first of the Grampus sloop, afterwards of the Mercury, in which he was present at the siege and capture of Quebec, by Wolfe. He gave eminent proofs of skill and resolution, in taking soundings of the river opposite to the French fortified camp, preparatory to an attack thereon, a difficult and dangerous service, which he performed so well, that he was afterwards employed to lay down a chart of the river from Quebec to the sea. This chart was published, and for a long time was the only one in use. His success in these employments is the more remarkable, as he appears never to have been taught surveying, nor even accustomed to use the pencil.

In the same autumn he was promoted to be master of the Northumberland man-of-war, in which he served till 1762, when the ship returned to England. During the winter of 1759-60, which he passed at Halifax in Nova Scotia, he employed the leisure which the season gave him in beginning the study of mathematics, with a view to qualify himself for the higher departments of his profession. In 1763 he went out to survey the Newfoundland islands; and in 1764, on the appointment of Sir Hugh Palliser to be Governor, Cook was appointed Marine Surveyor of Newfoundland and Labrador. The fruit of his labours during the four years in which he held that office, was embodied in his valuable charts of those countries.

The credit which he acquired in the discharge of his functions at Newfoundland, was the cause of his selection, in 1767, as a fit person to conduct a voyage undertaken into the South Pacific Ocean, for astronomical and geographical purposes. On this occasion Mr. Cook was promoted to the rank of lieutenant. For an account of the origin and objects of this undertaking, and the course of the voyagers as far as Otaheite, we refer to the article BANKS, SIR JOSEPH. The transit of Venus having been satisfactorily observed on the third of June, Cook resumed his voyage July 13, 1769, and after cruising for a month among the other Society Islands, sailed southwards in quest of the unknown continent, *Terra Australis Incognita*, which was formerly supposed to exist somewhere, as a counterpoise to the great mass of land in the northern hemisphere. Lofty mountains were seen October 6, and it was supposed that the object of their search was found. The land however proved to be New Zealand, which had not been visited by Europeans since it was discovered by Tasman in 1642. Cook spent six months in sailing round it, and found it to consist of two large islands, divided by a narrow channel: the warlike and savage temper of the natives hindered him from doing much to explore the interior. Sailing westward, he reached New Holland April 19, 1770, and ran down its eastern side from lat. 38° to its northern extremity at Torres Strait, lat. 10½°, where he took possession of the coast which he had explored in the name of Great Britain, and denominated it New South Wales. He then shaped his course towards New Guinea, and by passing between them proved what had been disputed, that New Holland and New Guinea were distinct islands. Of the various interesting adventures and narrow escapes which occurred to the navigators during their long sojourn among savage tribes and unknown seas, especially that difficult and tedious navigation of near 2000 miles along one of the most dangerous coasts in the world, we have no room to speak. Cook continued his voyage by Timor and the south coast of Java to Batavia (Oct. 9), where he was compelled to stay two months and a half to repair the ship, which had received most dangerous injuries among the coral reefs of New South Wales. The pestilential climate of Batavia proved very fatal to the ship's crew, already weakened by the hardships of their long voyage. Seven died at Batavia, and twenty-three more on the voyage to the Cape of Good Hope. June 12, 1771, the Endeavour anchored in the Downs.

Shortly after his return Cook was promoted to the rank of Commander. His journal and the papers of Mr. Banks were entrusted to Dr. Hawkesworth, who from these documents, and the materials of Captains Byron, Wallis, and Carteret, published an account of the several voyages of discovery undertaken during the reign of George III. into the Pacific, illustrated with plates and charts at the expense of government.

This voyage proved two things: first, that neither New Zealand nor New Holland were parts of the supposed southern continent; secondly, that no such continent could exist to the northward of 40° S. lat. It was now determined to send out a second expedition under Cook to explore the higher latitudes, and the Resolution, of 460 tons, and a smaller ship, the Adventure, Captain Furneaux—which parted company in the second year of the voyage—were commissioned for this purpose. Cook was instructed to circumnavigate the globe in high southern latitudes, prosecuting his discoveries as near the South Pole as possible, and making such traverses, from time to time, into every corner of the Pacific Ocean not before examined, as might finally and effectually resolve the much agitated question about the existence of a southern continent in any part of the southern hemisphere to which access could be had by the efforts of the boldest and most skilful navigator.

The two ships sailed from Plymouth, July 13, 1772, quitted the Cape of Good Hope Nov. 22, and traversed the Southern Ocean in high latitudes during near four months, between the limits of E. long. 20° and 170°, the extreme point to the southward being lat. 57° 15′. Having satisfied himself that no land of great extent could exist between these limits, Captain Cook made sail for New Zealand, which he reached March 26, 1773. After spending the winter months (our summer) among the Society Islands, he resumed his quest of the southern continent in November, proceeding eastward, principally between the 60th and 70th parallels of latitude, and from E. lon. 170° to W. lon. 106° 54′, where he reached his extreme southing, lat. 71°10′, where he was finally stopped by ice. Returning northwards, during the winter months he traversed the Pacific Ocean in the southern tropic, from Easter Island to the New Hebrides, and discovered another island, the largest in the Pacific except New Zealand, which he called New Caledonia. Thence he returned to New Zealand, to refresh the crew, and resumed his quest of a southern continent, November 10. Having sailed in different latitudes, between 43° and 56°, till the 27th, when he was in W. lon. 138° 56′, he gave up all hope of finding any more land in this ocean; and determined to steer direct for the western entrance of the straits of Magalhaens, with a view of coasting the south side of Tierra del Fuego, which at that time was very imperfectly known. December 29 he passed Cape Horn, and standing southward, discovered Sandwich Land, a desolate coast, the extreme point of which was named by him the Southern Thule, lat. 59° 13′, W. lon. about 22°, as being the most southern land which had been then discovered. Thence he ran to the eastward, nearly to the longitude of the Cape of Good Hope, and having thus encompassed the globe in a high latitude, and satisfied himself that no land of considerable magnitude could exist between the 50th and 70th parallels, he thought it inexpedient to prosecute his discoveries in those tempestuous seas with a worn ship and nearly exhausted provisions. Accordingly he made sail for the Cape, which he reached March 22, 1774, having sailed no less than 20,000 leagues since he left it, without meeting even with so trifling an accident as the loss of a mast or yard. July 30 he anchored at Spithead.

He was immediately raised to the rank of Post Captain, and received a more substantial reward for his services in being appointed a Captain of Greenwich Hospital. Men of science were powerfully interested, not only by his geographical discoveries, but by his unprecedented success during this voyage in preserving the health of his ship's company, of whom he lost only four, and only one of these by any sickness. His method consisted chiefly in a strict attention to diet, and to keeping the ship clean, well-aired, and dry. Much however was found to depend upon the care and influence of the commanding officer; for the crew of the Adventure, fitted out with the same provisions, had suffered considerably even at an early period of the voyage. On the day of Cook's admission to the Royal Society, March 7, 1775, a paper of his was read, giving an account of the methods. April 18, he communicated a second paper, relative to the tides in the South Seas; both of these are printed in the Philosophical Transactions, vol. lxvi. For the former the Society gave him the Copley medal, which is bestowed for the best experimental paper of the year. Of this second voyage he published his own journal, illustrated by maps and engravings; a supplementary volume containing the astronomical observations was published at the expense of the Commissioners of Longitude. The style is unpretending, clear, and manly, and, considering the imperfection of his education, does credit to his sense and ability.

While Cook was exploring the Southern Ocean, the attention of government was also turned towards discoveries in the Arctic regions. [North-West Passage.] It was not thought fair, after so many years of labour and anxiety, to request him immediately to forego his honourable ease; but when he volunteered his services, they were gladly accepted. Two ships, the Resolution and Discovery, the latter commanded by Captain Clerke, who had sailed with Cook in both his former voyages, were fitted out with every thing that could promote the health and comfort of the crews and the scientific objects of the voyage. They sailed from Plymouth July 12, 1776. Cook's instructions were to the following effect:—he was to proceed by the Cape of Good Hope to the Pacific, and to revisit the chain of islands lying along the southern tropic, in which he was to endeavour to disseminate and naturalize a variety of useful animals, to be carried from England and the Cape. He was then to bend his course northwards, and on reaching the western coast of America, to proceed with as little delay as possible to the latitude of 65°, and then to use his best endeavours to return to the Atlantic by the high northern latitudes, between Asia and America, thus reversing the usual course of Arctic voyagers. He arrived at the Friendly Islands too late in the spring of 1777 to attempt anything in the Arctic Seas that year. In December he took a final leave of the Polynesian Archipelago, and January 18, 1778, came in sight of an unknown group, to which he gave the name of Sandwich Islands, about 20° N. lat. Making no long stay, he reached the coast of America March 7, being then in 44° 33′ N. lat. In Nootka Sound, lat. 49° 33′, he stopped a month to put the ships in perfect repair before encountering the dangers of the Polar Seas, and proceeded, April 26, keeping near the coast whenever the state of the weather permitted. Following this course to the extreme northern point of the Pacific, he there examined a deep bay, afterwards named Cook's Inlet, concerning which strong hopes were entertained that it might lead to the long-sought discovery. These proving unfounded, he ran to the southward, along the narrow peninsula which forms the western boundary of the Kamtchatkan Sea; and after touching at Oonalashka, made sail for Behring's Straits. There he determined the position of the most westerly point of America, lat. 65° 40′, long. 168° 15′ W.; and ascertained it to be distant from the coast of Asia only thirteen leagues. August 18, he reached his extreme latitude, 70° 41′, where he was stopped by an impenetrable wall of ice. He continued to prosecute his search until August 29, when the daily increase of ice warned him to return. Before proceeding to the south, however, he spent some time in examining the sea and coasts in the neighbourhood of Behring's Strait, during which he had satisfactory proof of the correctness of that navigator, and made valuable additions to our geographical knowledge of that region.

Returning to winter at the Sandwich Islands, he discovered two which he had not before visited, Mowee and Owhyhee, the largest of the group. In sailing round the latter he spent ten weeks, from December 1 to February 13, 1779, without any serious disagreement with the natives, who, on the contrary, treated the English with the utmost respect. Speaking of the disappointment in not finding a northern passage, he uses the following words, which conclude his journal:—'To this disappointment we owed our having it in our power to revisit the Sandwich Islands, and to enrich our voyage with a discovery, which, though the last, seemed in many respects to be the most important that had hitherto been made by Europeans throughout the extent of the Pacific Ocean.' These pleasant anticipations were cut short by his tragical death. On the night of February 13, one of the Discovery's boats was stolen. Cook went ashore on the 14th to try to recover it; the natives became alarmed, blows were struck, and Cook was obliged to fire in self-defence. In retreating to the boats, four of the marines who attended him were killed, and Cook, who was the last person left on shore, was struck down from behind. He struggled vigorously; but the confusion of the boat's crews was such, that no assistance was given, and he was soon overpowered. His body having been left in the possession of the natives, his bones only were recovered, the flesh having probably been devoured. His remains were committed to the deep with military honours. Mr. Samwell, an eye-witness, has given the fullest account of this melancholy event, which he ascribed to no scheme of premeditated treachery, but to a sudden impulse, arising from the belief that the loss of the boat would be revenged by hostile measures. Captain Clerke succeeded to the chief command, and returned in the following summer to the Polar Sea; but he was unable to advance as far as in the former year: the voyage therefore failed in its chief object. The ships returned by China and the Cape to England, which they reached in October, 1780. An account of the voyage was published from Cook's Journal, continued by Lieutenant King. Charts and plates were executed at the expense of government, and one-half of the profits of the work were bestowed upon Cook's widow and children, upon whom a pension was settled.

As a navigator, Cook's merits were of the first order. He was thoroughly acquainted both with the practical and scientific parts of his profession, and possessed the qualities which fit men for responsible situations—a mind inventive, and full of resources, sagacity, self-possession, and decision, and an intuitive readiness of perception in professional matters; so that his first opinion as to a course to be pursued, the nature of an opening, tides, currents, &c., was seldom found to be incorrect. His perseverance was unremitting, and needed no relaxation nor respite. He was a strict disciplinarian, but watchful and solicitous in an uncommon degree for the health and comfort of his crews; and to this constant care and to his moral influence, as much as to his judgment, we must attribute that remarkable exemption from disease which his men enjoyed, in his two last voyages, through every variety of climate. He may be said to have banished that horrible disease, scurvy, from our naval service; and it is observed by Mr. Samwell, that his success in this respect afforded him more satisfaction than the reputatoin which attended his discoveries. [ANTISCORBUTICS, p. 119.] But that which we wish to point out in his character as most rare and truly estimable, was his scrupulous justice and humanity towards the rude tribes whom he visited. For their propensity to thieving he found a candid apology; and any offences committed against their persons or property by his own crew, he strictly punished; making it a rule to pay liberally, if required, for the slightest articles, even to grass, wood, and water. Nor did he give way to the gratifying of a natural curiosity, when by doing so he was likely to provoke a hostile collision. Once only he was betrayed into an unjust aggression, which ended in bloodshed; an act which he remembered with pain, and in his journal acknowledged to be an error, while explaining the motives which led to the commission of it. The same benevolence and steady principle which he displayed in public, he carried into the private relations of life. His constitution was robust, inured to fatigue, and patient of self-denial.

(See Kippis's *Life of Cook*, which is inserted, entire we believe, in the *Biographia Britannica;* the several voyages to the Pacific Ocean; Samwell's *Narrative of the Death of Captain Cook*, which is printed in the *Biographia.*)

COOKE, BENJAMIN, a highly-distinguished composer and organist, who during the latter half of the last century supported and advanced the science of music, both by his works and precepts. He was the son of Benjamin Cooke, a music-publisher in New-Street, Covent Garden, and before he had attained his ninth year became the pupil of the celebrated Dr. Pepusch, under whom he made such progress, that when only twelve years old he was found capable of doing the duty of organist at Westminster Abbey, as deputy of Mr. Robinson, son-in-law and successor to Dr. Croft. On the death of Pepusch in 1752, Cooke was chosen as conductor of the *Academy of Antient Music*, which office he held till the year 1789, when he relinquished it to Dr. Arnold. In 1757 he succeeded Bernard Gates as lay-clerk and master of the choristers at Westminster Abbey, and in 1762 was appointed organist of that venerable church. In 1777 the University of Cambridge conferred on him the degree of Doctor in Music. In 1782, after a severe contest, in which Dr. Burney was his chief opponent, he was elected organist of St. Martin-in-the-Fields. In 1784 he was nominated by George III. as one of the sub-directors of the famous Commemoration of Handel. He died in 1793, leaving two sons—Henry, still living, who formerly held a very respectable situation in the Post Office, and Robert, who followed his father's profession, and became organist of the Abbey on the decease of Dr. Arnold; but shortly after, in a fit of insanity, threw himself into the Thames, and was drowned, to the grief of his numerous friends, by whom he was much valued, both for his talents and moral qualities.

Dr. Cooke's compositions were chiefly for the Academy of Antient Music, the Church, and the Catch Club. For the first he made the important additions, so well known to connoisseurs, to Galliard's Morning Hymn. For the second he wrote a charming service and two lovely anthems. To the highly-distinguished Catch Club, he contributed his fine glees, 'In the merry month of May,' 'How sleep the brave,' 'Hark! the lark,' 'As now the shades of eve,' &c.; and obtained seven of the gold prize medals given by that elegant and useful society. He was the intimate friend of Sir John Hawkins, the musical historian—who profited much by the occasional hints of so learned a professor—and the master of some of the deservedly celebrated musicians of the last and present age, among whom it would be an act of injustice to Dr. Cooke not to name Parsons, Greatorex, Knyvett senior, Crosdill, Spofforth, Bartleman, Beale, Walmisley, &c. (*Harmonicon*, vol. ix.)

COOKE, GEORGE FREDERICK, a popular actor, was born in the city of Westminster, April 17th, 1755. He was the son of an officer in the army, and his mother's maiden name was Renton. On the death of her husband she went to reside at Berwick upon Tweed, where George was educated. At the usual age he was articled to a printer; but having imbibed a strong passion for the stage, he appeared, after various essays in private, as a professed actor at Brentford, in the character of Dumont in the tragedy of 'Jane Shore.' In 1778 he made his debut in London, at the Haymarket theatre, for a benefit, but without attracting any particular attention. After a period of two-and-twenty years, during which he became the hero of the Dublin stage, he returned to London, and made his first appearance at Covent Garden theatre, Oct. 31, 1800, in the character of Richard III.: his success was decided; and for ten years he divided the favour of the town with Mr. John Kemble. In 1810 he sailed for America, and arrived at New York on the 16th of November, in which city, intemperance having been long undermining a wonderfully strong constitution, he expired on the 26th of September, 1812, aged 57 years and 5 months. His most popular characters were, in tragedy, Richard III., Iago, and Shylock; and in comedy, Kitely, Sir Archy Macsarcasm, and Sir Pertinax Macsycophant. Mr. Kean, in one of his visits to America, caused a monument to be erected over his grave. His memoirs were published by his friend Mr. Dunlop from a MS. journal kept by Mr. Cooke for many years, and other equally authentic documents, in 2 vols., 8vo., London, 1813.

COOLER. Various contrivances have been adopted by brewers and distillers for cooling their worts. This has been done by exposing the hot liquor in shallow wooden vessels to the air, and by the use of stirrers or fans to keep the liquor in motion, and thus expose fresh surfaces to the air.

The plan has also been adopted of passing spring-water, which in deep wells is usually about 52° even in summer time, through metal pipes placed in the liquor to be cooled.

Wine-coolers are made of porous earthenware, which being soaked in and saturated with water, by its gradual and copious evaporation occasions cold; and in Spain water-coolers, called alcarrazas, are made on the same principle. Coolers of this kind, made of porous clay, lightly baked, and rather thin, are also common in Egypt, where they are often represented on the antient monuments in a form very much resembling both those now used in Egypt, and such as we see in use at Cadiz and other places in the South of Spain. On the monuments of Egypt we sometimes observe a man fanning these earthen vessels with a palm-leaf, in order to promote the evaporation. The Arabs of Egypt are well acquainted with the practice of fanning their earthen vessels to quicken the evaporation. M. Costaz, when in Egypt, made the following experiment on the refrigerating power of these earthen vessels. The thermometer in the shade, but exposed to the air, marked 110°.75 Fahrenheit during the greater part of the day. At sunset the Nile water was 82°.6; an earthen vessel filled with this water was placed on the deck of the boat in which M. Costaz passed the night on the Nile. At day-break the temperature of the river was the same, but that of the water in the jar was only 61°.25, and more than half of the water was evaporated.

COOPER. [SHAFTESBURY, EARL OF.]

COORDINATES mean lines, angles, &c. ranged in order. The notion from which the word arose was this, that when the positions of consecutive points on a curve are referred to given points or lines by means of lines (as in ABSCISSA) or angles, those lines or angles present a succession of *arranged* data, by which the several points of the curve may be treated *in order*. It was Descartes who first used coordinates in the second book of his geometry, and the words in which this now all-pervading method of expression was announced are as follows: 'Eligo rectam aliquam lineam, veluti AB, ut ad diversa ejus puncta referam omnia puncta hujus curvæ lineæ CE; deinde eligo etiam punctum aliquod in AB, veluti A, ad *ordiendum* ab eo calculum.' We do not find the word in Schooten, Beaune, or others of the immediate school of Des Cartes. De Witt calls the abscissa *crus patiens*, and the ordinate *crus efficiens*. Coordinates (so called) are used in the writings of John Bernoulli, but in Newton the phrase for them is 'lineæ ordinatim applicatæ:' in later times the use of the word has become universal. Coordinates either determine the position of a point in space, or in a plane which is understood to contain all the figure under consideration, as in the first six books of Euclid. They determine position either by straight lines only, or by a straight line and angles: in the latter case they are called *polar* coordinates.

1. Rectilinear coordinates in a plane. In the given plane draw two straight lines meeting in a point O (called the *origin*). From any point P draw parallels to the two lines just named: the parts intercepted between P and these lines (called *axes*) are the coordinates of the point. When the axes are at right angles, the coordinates are said to be *rectangular;* when at any other angle, *oblique*. [ABSCISSA.]

2. Rectilinear coordinates in space. Through any point O (the origin) draw three planes which intersect in right lines (the axes). Through any point P draw parallels to the axes: the parts intercepted between P and the coordinate planes (three in number) are the coordinates of P.

3. Polar coordinates in a plane. Choose any point O in the plane, and any right line O A passing through O. Then taking any point P, the distance O P (called the *radius vector*) and the angle P O A (which has no distinct name, but might be called the *vectorial* angle) are the polar coordinates of P.

4. Polar coordinates in space. Choose a plane (M), a point O, and a line O A, in the plane M. Take any point P above or below the plane, and let fall P B, a perpendicular on (M) meeting (M) in B. Then the radius vector O P, and the angles P O B and B O A are the polar coordinates of P. In astronomy, if O be the earth's centre, O A the line passing through the equinox, and (M) the plane of the ecliptic; then B O A is the longitude of P, and P O B its latitude. But if (M) be the plane of the equator, then B O A is the right ascension of P, and P O B its declination.

COORG, or **CADUGA**, a small principality which occupies the eastern part of the mountain range called the Western Ghauts, and extends from the Tamberacherry pass, on the south, in 11° 25′ N. lat. and 76° 20′ E. long., to the river Hennavutty, on the confines of Bedune, on the north, in 12° 42′ N. lat. The greatest length is about 70 miles, and the mean breadth about 22 miles. On the north it is bounded by Canara and Mysore, on the west and south by the province of Malabar, and on the east by Mysore. The country presents a succession of hills and valleys, placed at a medium elevation between the sultry plains and the tempestuous tops of the mountains; it enjoys a temperate climate, and has a fertile soil: in many parts it is well cultivated, but in others is overrun with jungle, which is the resort of wild elephants and many beasts of prey: some considerable forests also occur, and from these a good deal of sandal-wood is obtained. The Tungha and Bhadra, which after their junction are called the Toombuddra and the Cavery, have their sources in the Coorg country, which is so well watered and subject to so much rain, that rice is produced in sufficient abundance, not only for the inhabitants, whose principal food it forms, but also for exportation to Mysore: a considerable quantity of cardamom seeds are raised and exported. There is besides abundance of excellent pasturage, and great numbers of cattle are reared. The manufactures of the country are confined to a coarse kind of blanket, which forms part of the dress of the common people: the cotton cloths which they use are all imported. Periapatam, in 12° 22′ N. lat. and 76° 11′ E. long., was formerly the capital of the principality, but its proximity to the Mysore territory, the distance from Seringapatam being only 37 miles, occasioned it to be abandoned in favour of Mercara, which is now the residence of the rajah and the seat of his government. This town stands surrounded by an amphitheatre of hills, in 12° 26′ N. lat. and 75° 30′ E. long. The fort is a pentagon, with towers and bastions; within this is the rajah's palace, which is handsomely furnished in the European style.

The rajah of Coorg is mentioned by Ferishta as an independent prince in 1583. Many vain attempts were made by the Mysore rajah to subgugate the country, but a dispute about the succession having arisen between two brothers, Hyder Ali offered his mediation, and this being accepted, he by treacherous means obtained possession of the territory. One of the brothers he destroyed, together with his family, and the other he kept prisoner in the fort of Cuddoor, on the eastern frontier of Bednore. This rajah dying in 1779, Hyder put aside his son, whom he confined in Periapatam, and parcelled out the country into jaghires among several petty Mohammedan chiefs. After a confinement of eight years, the young rajah, Beer Rajindra, was released from his confinement by twelve of his subjects, chiefs of villages, who for that purpose repaired in disguise to the place of his confinement. His standard was immediately joined by all ranks of his people, and the invaders were with some difficulty driven out. This prince, Beer Rajindra, was a man of enlarged mind and noble disposition, and during his reign he succeeded in preserving order within his dominions, and in conciliating the affection of his subjects. At his death, in 1808, he left the succession to an infant daughter, to the exclusion of his brother, to whom of right it belonged according to antient usages; but the young ranny or princess having abdicated in favour of her uncle, with the sanction of the British government and to the satisfaction of the Coorg people, the country has since remained tranquil and prosperous. (Mill's *History of British India;* Buchanan's *Journey through Mysore, Canara, and Malabar;* Heyne's *Statistical Tracts on India.*)

COPAIBA or **COPAIVA**, an oleo-resin or turpentine (incorrectly termed a balsam, since it is destitute of benzoic acid), is procured not merely from the Copaifera officinalis (Willd.), a native of Venezuela, also naturalized in the Antilles, but from ten or twelve species, chiefly natives of Brazil. It varies in appearance and qualities according to the species from which it has been procured, and likewise according to the age of the tree and the time of the year. Incisions are made in the tree, from which flows a liquid differing little in consistence from thick sap. It is collected in calabashes, after which the incisions are closed with wax or clay. The incisions are repeated in general three times each season. The fluid is brighter or darker in colour, more or less rich in volatile oil, more acrid or more bitter, according to circumstances. It is mostly of a light yellow colour, clear and transparent, seldom turbid or cloudy; odour peculiar, volatile; taste oily, mild, slightly aromatic, at last acridly bitter. Specific gravity 0.966 to 0.997, according to its age. Exposed to heat in a platinum spoon, it is entirely consumed with a white smoke. In a state of purity, it consists of a volatile oil, in the proportion of 40 to 45 per cent., and 50 per cent. of an acid crystallizable resin. The oil may be separated by distillation, or by means of mixing equal parts of copaiba with alcohol of specific gravity 0.837, shaking them diligently, then mixing 100 parts of the copaiva which has been so treated with 37½ parts of a ley of caustic soda, to be again well shaken; after which 150 parts of water are to be thoroughly agitated with it, and the whole left to rest. The specific gravity of the oil thus obtained is 0.900. A slight difference exists between the oil thus procured and that by distillation. Both are used in medicine; indeed the oil is the active principle of copaiva, the resin being of very secondary importance. The oil is destitute of oxygen, and may be employed for the preservation of potassium.

Copaiva is frequently adulterated: the presence of any extraneous matters may be known by the manner in which the suspected portion conducts itself towards solvents and re-agents. Copaiva is occasionally mixed with castor-oil, almond, poppy, nut-oil, and the finer sorts of turpentines. All fixed oils (except castor-oil, the presence of which may be detected by sulphuric acid, but the accuracy of this test is called in question by Brandes) separate from it by being allowed to remain at rest. Good copaiva should be perfectly soluble in alcohol of the strength of 90 per cent. It is soluble in all known æthers, and in the volatile and fixed oils. Three parts of copaiva with one of caustic ammonia of specific gravity 0.950 form by agitation a clear soap. The simplest test of the purity of copaiva is to heat a small quantity in a watch-glass, when, if good, a hard brittle resin remains, which has considerable analogy with styracin. The crystals which form in this resin are six-sided prisms, and have the property of polarizing light.

A kind of copaiva is obtained in St. Domingo from the

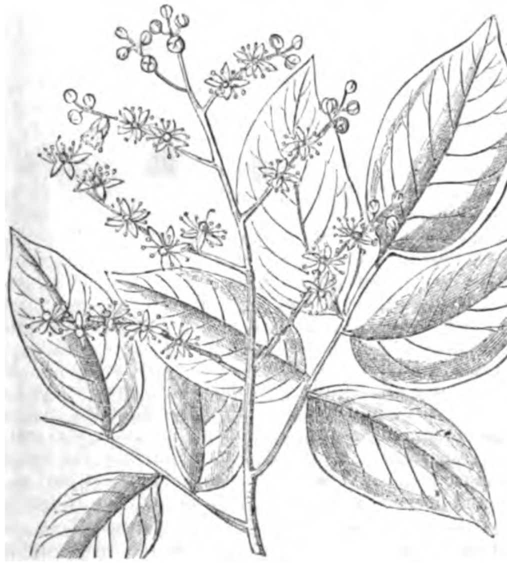
Croton origanifolius (Lamarck); in Java and elsewhere the juice of the Canarium commune (Linn.) is found to possess similar properties.

Copaiva acts as a stimulant to the mucous surfaces, especially of the rectum and urino-genital passages: when the dose is small, it influences the kidneys and urethra; but if large, the rectum. It is chiefly used to lessen increased discharges from those organs, and if judiciously employed, generally effects this object; but if given prematurely or in too large a dose, it seldom fails to aggravate the complaints and occasion other serious symptoms. It has likewise been beneficially given in affections of the mucous membrane of the lungs, such as chronic bronchitis, which must be carefully distinguished from true phthisis pulmonalis or consumption, a disease in which it cannot fail to prove injurious.

Various means have been devised to conceal the disagreeable nauseous taste of copaiva without impairing its qualities. Calcined magnesia thickens it, and permits it being made into pills; an ætherial or alkaline solution will also retain the virtues, and lessen the repulsive taste.

COPAI'FERA OFFICINA'LIS, the plant from which balsam of copaiva is procured, is a tall handsome tree, with a fine head, found wild in the Spanish Main, and occasionally seen in Martinique, where it has been introduced. The leaves are pinnated, alternate, with lanceolate-ovate leaflets of a somewhat leathery texture and a shining surface, perfectly entire, and two or three inches long. The flowers grow in axillary panicles, densely collected towards the ends of the branchlets, white, and about eight in a cluster.

The tree, according to Jacquin, is common about the town of Tolu, thirty leagues from Carthagena, growing promiscuously with the species that yield balsam of Tolu, balsam of Peru, and similar secretions.



COPAL, a resin possessed of peculiar properties, the produce of the Rhus copallinum, a native of Mexico; it is in rounded masses, smooth and brittle, transparent or nearly so, without colour, or having a slight tinge of yellow: it has but little taste, and is nearly inodorous; it is insoluble in water, fusible, and inflammable. It differs from most other resins in its very sparing solubility in alcohol; and of the little that dissolves with the assistance of heat the greater part is deposited as the solution cools. It is dissolved by æther and some essential oils.

COPAL VARNISH, is the substance for preparing which this resin is most employed. It is probable that every manufacturer has his peculiar mode of proceeding: Tingry prepares the simple copal varnish by heating eight ounces of oil of turpentine in a matrass with the heat of a salt-water bath; as soon as this reaches its boiling point, he gradually throws in an ounce and a half of copal reduced to powder, keeping the vessel in a state of circular motion. This author further states that to obtain this varnish colourless, the rectified oil is to be exposed previously to the sun for some months in bottles, leaving an interval of some inches between the cork and the surface of the liquid; by this the oil undergoes some change, which renders it a better solvent of copal.

The varnish thus prepared is stated to be exceedingly durable and brilliant; it resists scratches, and is susceptible of a fine polish. Tingry particularly recommends it to be applied to philosophical instruments. There are several modifications of this varnish used for particular purposes, as with the addition of oil of lavender and oil of lavender and camphor, an account of which may be seen in the author above named.

COPENHAGEN, or KIOEBENHAVN, one of the six royal districts into which the Danish province of Seeland is divided, comprises the centre of the eastern portion of the island of Seeland and the islands of Amager (Amak) and Saltholm. It is bounded on the north, south, and west by other districts of Seeland, and on the east by the Sound and the Baltic. It contains an area of about 525 square miles, which are divided into three probsteien or provostships, each of which contains two harden or circles. Exclusive of the capital, the population is about 40,000; inclusive of it, the numbers are about 156,000; it has 78 parishes, 4 towns, besides the capital, and 197 villages. This circle is on the whole very fertile.

COPENHAGEN, the metropolis of the kingdom of Denmark, is situated partly on the eastern coast of the island of Seeland, and at the southern extremity of a gulf in that narrow channel of the Baltic called the Sound, which is here about 14 miles broad, and partly on the northern coast of the small island of Amager or Amak. It lies in 55° 42′ N. lat., and 12° 34′ E. long., is about 5 miles in circumference, 1⅞ in length, and 1¼ in breadth; and is divided into three principal districts—the Old Town or Aldstadt, the New Town or Friedrickstadt, and Christianshavn. These three quarters are surrounded by ramparts and ditches, and defended by 24 bastions, besides outworks, and towards the sea by a very strong citadel. Without these lines are the three suburbs of the North Bridge, East Bridge, and West Bridge. Altogether Copenhagen is one of the finest capitals in Europe. It is divided into 12 quarters, and contains 10 public squares, 5 market-places, 3 royal palaces, 9 parochial churches, a Roman Catholic chapel, 5 synagogues, 3 religious foundations, 13 hospitals, a foundling asylum, and 30 poorhouses. Its aspect, on emerging from the narrow entrance into the port, which is capable of containing 500 merchant vessels, besides the whole navy, is very grand and striking.

The Old Town, or what is called the City, is the most southern quarter. It is separated from the New Town by a canal and the 'Gothic Street,' and united to Christianshavn by a bridge; it is large and populous, has a fine appearance, and contains the spacious area called the New Market, which is embellished by the palace of Charlottenburg. Here also is the royal palace of Christianberg, built by Christian between 1732 and 1740. It was burnt down in 1795, but is now nearly restored, and is one of the finest buildings in Europe. It contains a magnificent palace-church, the royal galleries of paintings, natural history, &c., in a series of twelve saloons; the library, in which are 400,000 volumes, a valuable collection of engravings, and the marble sculptures and casts of Thorwaldsen. The other remarkable buildings in this quarter are Prince Frederick's palace; the palace of Charlottenburg, above mentioned, and now occupied by the Academy of Arts, a picture gallery, and a repository for the artillery, &c.; the bank, exchange, new town-hall, and Trinity church, on the top of whose singularly constructed round tower, which is 115 feet high, an observatory is erected; and the university with four colleges, which was founded in 1478 by Christian I. This university is attended on an average by 700 students, and has a library of 60,000 volumes, a collection of MSS. relative to northern and Icelandic history, a museum of northern antiquities, a botanical garden, a cabinet of natural history, a theatre of anatomy, &c.

The New Town, which is the most northern quarter of the city, and of which Fredrickstadt is the finest portion, is laid out in broad streets, and contains the handsomest buildings in Copenhagen. Here is the antient royal palace of Rosenberg, in which are deposited the crown jewels, a beautiful collection of antiquities, and a cabinet of coins and medals; its ample gardens form a public promenade. Frederick's place, a noble octagonal space, is chiefly formed by the Amalienborg, a structure composed of four large palaces—those of the king, the prince royal, the king's brother, and the naval school; one of the sides is open, and is embellished with a beautiful equestrian statue of Frederick V.

The third division of Copenhagen is Christianshavn, situated on the island of Amager, and united to the town by two bridges thrown across the narrow arm of the sea which separates Amager from Seeland; it forms an admirable harbour, which is the great naval station of Denmark, and is capable of containing above 500 ships. In this quarter, which presents regular well-built streets and handsome squares, is St. Saviour's church, the finest in Copenhagen, with its singular tower, 288 feet in height; the beautiful Frederick's church; and the warehouses of the Danish East India Company. In this direction are situated the two smaller islands of Old and New Holm, which contain the stores, dockyard, slips, and arsenals of the fleet, &c.

Copenhagen is the seat of a bishopric. It contains altogether 29 Protestant churches, a Roman Catholic chapel, 3 synagogues, 22 hospitals, (one of which accommodates above 2000 patients,) a naval hospital for 1000, and other benevolent institutions for human infirmities. The city possesses also a museum for northern antiquities, the Claasen library for mathematics, natural history, &c., containing above 34,000 volumes; a royal museum of the arts, cabinets of coins, mechanical objects, &c.; a naval and military cadet academy, 114 schools of various descriptions, a mechanics' institute, conservatory of music, &c. The principal learned societies are the Royal Academy, the Society for promoting Northern History and Languages, a Society of National Economy, Societies for Icelandic Literature and for Northern Antiquities, a Bible Society, &c.

The population in 1797 amounted to 85,161; in 1829 to 111,997, of whom 54,950 were males and 57,047 females; and at present it is about 116,000, including 2600 Jews. The chief source of employment is commerce and navigation, which is greatly promoted by the East India Company and various commercial associations. Though Denmark is rather an agricultural than a manufacturing country, there are a great number of manufactories in Copenhagen, which afford occupation to above 3000 persons; among them are 242 brandy distilleries, 50 breweries, 5 vinegar distilleries, 9 sugar refineries, 8 soap-boilers' works, 32 manufactories of tobacco, 21 of cloth, 23 of cotton goods, 18 of hats, 24 of gloves, 29 of linen and cordage, 3 of silk, 29 tanneries, 5 iron-founderies, &c. General trade has much declined, principally in consequence of Altona being a free port, which Copenhagen is not. The East and West India trades are however still pursued to much advantage.

Copenhagen is said to have been founded by Bishop Axel in 1168, when it was only a poor hamlet of fishermen; but as a town Copenhagen dates only from the thirteenth century, and as a city since 1443 only, when, having been much enlarged, it received municipal privileges, and became the royal residence. On the 27th of May, 1660, the peace of Copenhagen was concluded in the camp of Copenhagen, after the Swedes had in vain endeavoured to reduce it by a siege: on the 2nd of April, 1801, Lord Nelson gained here a great naval victory over the Danish fleet. It has frequently suffered much from conflagrations as well as from hostile bombardments, especially during that by Lord Cathcart, in 1807, when 308 houses were totally burnt, 2000 considerably injured, and 1106 inhabitants killed; but it has nearly recovered from these disasters.

The climate is damp and unhealthy; the water is of a bad quality; and the mortality is said to be greater than in any other town in Denmark. In the neighbourhood of Copenhagen are the king's summer palace of Fredericksberg, a splendid structure with delightful gardens, in the church attached to which the kings of Denmark are anointed: another royal palace, a fine specimen of the architecture of the middle ages, is at Roeskilde, a small town where the royal remains, particularly of the Oldenburg line, are deposited; and at Jaeger Preis is another royal residence, where many great men of the north are interred—among others, Bernstorf, the celebrated Danish statesman, and Tycho Brahé.

COPE'RNICUS, NICOLA'US. The real name was Copernik, or, according to others, Zepernic. We shall not discuss either this, or the somewhat more important question, whether he was born, as Junctinus asserts, at 38 minutes past four on the 19th of January, 1472, or, as Mœstlinus asserts, at 48 minutes past four in the afternoon, February 19, 1473. Morin adopts the date of the latter, but remarks that the horoscope was a most happy one for talent, as appears by the nativity given by the former.

The principal authorities for the life of Copernicus are the account of Gassendi, published with the life of Tycho Brahé [BRAHE', TYCHO]; the *Narratio*, &c. of RHETICUS, and an account prefixed to his Ephemeris for 1551. The latter two we have not seen, but Gassendi cites abundantly from them. Weidler also mentions Adamus, *Vit. Phil. Germ.* There is nearly a literal translation of a large part of Gassendi's life in Martin's *Biographia Philosophica*; a sufficient abstract in Weidler, and a full account of the writings of Copernicus in Delambre's *Hist. de l'Art Mod.*, vol. i.

Copernicus was born at Thorn, in Prussia, a town on the Vistula, near the place where it crosses the Polish frontier. His family was not noble; but his uncle, Lucas Watzelrode, was bishop of Warmia (episcopus Warmiensis), whence it is frequently stated that Copernicus afterwards settled at a town of that name; whereas the cathedral was situated at Frauenburg, a town on the coast, near the mouth of the Vistula, and, as to social position, about 50 miles both from Königsberg and Danzig. Copernicus was educated first at home, and then at the university of Cracow, where he became doctor of medicine. He paid more than usual attention to mathematics, and afterwards to perspective and painting. A portrait of himself, painted by himself, passed into the possession of Tycho Brahé, (see his *Epistles*, p. 240,) who wrote an epigram on it, the point of which appears to be (the portrait being a half-length) that the whole earth would not contain the whole of the man who whirled the earth itself in ether. After the completion of his studies at Cracow, Copernicus went to Italy, and stayed some time at Bologna, under the instruction of Dominico Maria. His turn for unusual speculation began to appear in his having at this time the notion that the altitude of the pole was not always the same at the same place. He was certainly at Bologna in 1497, and by the year 1500 he had settled himself at Rome, as appears by astronomical observations which he is recorded as having made. At Rome he gave public instructions, and [in some official capacity (magno applausu factus mathematum professor): he is said, while thus engaged, to have established a reputation hardly less than that of Regiomontanus. In a few years, but the date is not precisely stated, he returned to his native country, where (having taken orders, we suppose, in Italy) his uncle gave him a canonry in his diocesan church of Frauenburg. There, after some contests in defence of his rights, not very intelligibly described, he passed the rest of his days in a three-fold occupation—his ecclesiastical duties, his gratuitous medical practice among the poor, and astronomical researches. He went very little into the world; he considered all conversation as fruitless, except that of a serious and learned cast; so that he formed no intimacies except with grave and learned men, among whom are particularly recorded Gysius, bishop of Culm, and his pupil and follower, the celebrated Rheticus. A large mass of his epistles is said by Gassendi to have fallen into the hands of Broscius, professor at Cracow, but none have been published. He was all this time engaged as well in actual observation as in speculation. His instrumental means, however, were not superior to those of Ptolemy; and he perfectly well knew the necessity of improvement in this department. 'If' (said he to Rheticus, whose Latin has certainly been misprinted, but in a manner which leaves the meaning sufficiently clear,) 'I could determine the true places of the heavenly bodies within ten seconds of a degree, I should not glory less in this than in the rule which Pythagoras has left us.'

Copernicus was struck by the complexity of the Ptolemaic system, and searched all antient authors to find one of a more simple character. The earth stationary in the centre of the universe, the planets moving round it carried on enormous crystalline spheres, (for though many might use this as mere hypothesis, the refutation of Tycho Brahé from the nature of the orbits of comets shows that he considered the *material* spheres as one of the opinions of his day,) and finally the enormous sphere of the fixed stars, carried round once in every 24 hours, struck him with a feeling that such a system could not be that of nature.

He found in Martianus Capella and others proofs that an opinion had formerly prevailed to some extent that Mercury and Venus, at least, moved round the sun; that the Pythagoreans held the rotation of the earth; and that Philolaus had even imagined the earth to have an orbit round the sun. It is very doubtful to what point these several opinions were carried, or on what grounds they were supported: it is sufficient for our purpose here that Copernicus found such doctrines attributed to the sects and persons above mentioned, and took them into consideration, with a view to see how far phenomena could be made to follow from them with more simplicity than in the system of Ptolemy. At what time he finally adopted his own system is not very clear; his work was completely written in 1530, and from that time he did nothing except to add and alter. And since Copernicus says, in his epistle to Paul III., that he had been very long pressed by his friends to publish, the above date is not improbable. In the mean while his opinion was circulated even among the vulgar; and he was satirized on the stage at Elburg. His reasons had convinced Reinhold, Rheticus, Gysius, and others; and upon the representations made to him, Cardinal Schonberg was desirous of having the work printed, and wrote to Copernicus to that effect from Rome in 1536. But though backed by a cardinal, a bishop, and two of the most learned astronomers of the age, Copernicus was well aware of the odium which an attempt to disturb established opinions would excite; and it was not, it seems, till about 1541, that a tardy consent was extorted from him. The work was accordingly delivered to Gysius, and by him to Rheticus, who, thinking that it would be best printed at Nuremberg, entrusted it to Andrew Osiander, who superintended the printing, and wrote the remarkable preface, which is always attributed, and even by Delambre, to Copernicus himself. This is explicitly stated by Gassendi, and the reason assigned is the obvious one that Osiander (besides thinking it necessary to print the cardinal's request) was afraid of shocking public opinion, and thought it best to represent the scope of the work, not as actually affirming the motion of the earth, but as using such an hypothesis for the more simple and ready calculation of the heavenly motions.

He says, 'It is not necessary that hypotheses should be true or even probable; it is sufficient that they lead to results of calculation which agree with observations.' He points out the admitted defects, and admitted unlikelihood, of several points of the Ptolemaic system; requires that the new hypothesis should be admitted on the same footing as the antient ones, and ends thus—'Neither let any one, so far as hypotheses are concerned, expect anything certain from astronomy, since that science can afford nothing of the kind; lest, in case he should adopt for truth things feigned for another purpose, he should leave this study more foolish than he came.'

With such safeguards, headed by the urgent request of a cardinal, and dedicated, probably by permission, to the pope, the work was ushered into the world, of which it was the ultimate destiny to help largely in overthrowing submission to authority in matters of science, whether to the doctrines of the Greeks or to the reputed interpretation of the sacred writings. The title-page is as follows:—

NICOLAI CO-
PERNICI TORINENSIS
DE REVOLVTIONIBVS ORBI-
um cœlestium libri vi.

Habes in hoc opere iam recens nato & ædito, studiose lector, Motus stellarum, tam fixarum quàm erraticarum, cum ex ueteribus tum etiam ex recentibus obseruationibus restitutos: & nouis insuper ac admirabilibus hypothesibus ornatos. Habes etiam tabulas expeditissimas, ex quibus eosdem ad quoduis tempus quàm facilli me calculare poteris. Igitur eme, lege, fruere.

'Αγεωμέτρητος ἐδεὶς εἰσίτω

Norimbergæ apud Ioh. Petreium.
Anno M. D. XLIII.

The taste of what we should now call the puff in the title-page is doubtless that of Osiander, to whom it is due that the great work of Copernicus contains an expression of recommendation to *buy* it in the title-page, being the only instance of the kind we know. The second edition, edited by Rheticus, was published at Basle, 1566, and is little esteemed; the third, edited by Muler, was printed at Amsterdam in 1617, and again in 1640, with notes: it is the most correct of the three. This same Muler, in his Tabulæ Frisicæ, Alcmaar, 1611, has reduced the hypotheses of Copernicus to the form of tables.

We now come to the description of the *Copernican* system, by which we mean, the system actually promulgated by Copernicus, and not the Keplerian, Galilean, Newtonian, Halleian, Laplacian, &c., system which bears the name. We have before remarked [BRAHE', TYCHO], that it is customary to call all existing notions on the system of the world, Copernican. This matters little, considered as a mere method of expression; but it becomes of consequence when, by means of it, a degree of lustre is thrown on the speculations of Copernicus, which, properly considered, they do not need, and, critically examined, they will not bear. We are accustomed to see Copernicus represented as a man so far in advance of his age, that in the main points of his system nothing has been added and nothing subtracted. The plates in our elementary works show, under the heading of 'the Copernican system,' planets, satellites, and comets, all with orbits such as the latest discoveries have assigned. We shall therefore exhibit the 'Copernican system' as far as we can in the words of its author (translated, of course), and at greater length than would have been necessary had no misconception prevailed. It will hardly be supposed that we intend an absolute depreciation of the merits of one of the most original talents that ever existed. Copernicus was a mathematician of the first order, a sincere lover of truth, a mind free from trammels to an extent which was then almost unknown, and which we should have deemed almost incredible had we not had the proof before us. It is no easy thing for us to conceive the state of a head furnished in youth with theories upon all things in heaven or earth, proved in as many words by the assertion that Aristotle said it.

The work 'De Revolutionibus,' &c., consists of an introductory dedication to Paul III., and six books. In the former Copernicus distinctly informs us that, being discontented with the complexity of the prevailing systems, he closely examined all the writings of the ancients, to see if he could find anything better. He found the testimony of Cicero and Plutarch, as to the opinions of Nicetas, Pythagoras, and Philolaus. He thereupon claims for himself the same licence, adverts to his hypothesis as purely fictitious, and says, 'Quamvis absurda opinio videbatur, tamen quia sciebam aliis ante me concessam libertatem, ut quoslibet fingerent circulos ad demonstrandum phenomena astrorum. Existimavi mihi quoque facile permitti, ut experirem, an posito terræ aliquo motu firmiores demonstrationes quàm illorum essent, inveniri in revolutione orbium cœlestium possent.' With regard to the word demonstration, it must be particularly remembered that at this period the term, as applied to astronomy, always meant a showing how the thing would happen if the supposition were true, not a proof of the supposition itself. Thus, in this sense, the supposition of a daily motion of the sun round the earth may be made to yield a perfect *demonstration* of the phenomena of day and night; and it would be legitimate to say that of two hypotheses, one false and one true, the false one might give *truer demonstrations* of the celestial motions than the other.

The first book contains the propositions—1. That the universe is spherical; which is proved by old reasons, such as that a sphere is the most perfect figure, &c. 2. That the earth is spherical; for which he gives the same reasons as are now given. 3. That the earth and sea make one globe. 4. That the motions of all the heavenly bodies must be either uniform and circular, or compounded of uniform and circular motions. Nothing but circular motion, he asserts, could reproduce phenomena periodically; and he maintains that a *simple* body must move circularly. 5. He examines the questions whether the earth can have an axical and an orbital motion, and satisfactorily shows that, supposing the distance of the fixed stars to be immense, there is no astronomical reason to the contrary. 6. He gives what he imagines to be a proof that the sphere of the fixed stars is immensely distant. It must be observed that he has no notion of a universe of stars unequally distributed throughout space. 7 and 8. He examines and argues against the reasons of the antients for placing the earth in the centre of the universe, by considerations which are as purely imaginary as those against which he was contending. He says that circular motion must be that of a whole, rectilinear motion that of a part separated from its whole; and from this assumption he deduces the falling of a body to the earth. That rectilinear and circular motion can exist together is, according to him, a thing of the same kind as the notion of a horse existing with that of an animal. He is throughout possessed by the opinion that there must be a *centrum mundi*, or fixed point in the middle of the universe, which, however, he considers to be the sun, not the earth. It is needless to say that the centrum mundi forms no part of the Newtonian system. 9. He contends for the possibility of the earth having several motions. 10. He establishes the order of the planets, remarks that it is impossible to explain the motion of Mercury and Venus upon the supposition of the earth being their centre, and observes that the motion of the other planets round the sun is perfectly possible, consistently with that of the earth, if the radii of their orbits be made large enough. He draws a diagram of the system in the manner now usual, and concludes with the following words, which must be considered as the first announcement of the system:—'Proinde non pudet nos fateri hoc totum, quod luna præcingit, ac centrum terræ per orbem illum magnum inter cæteras errantes stellas annuâ revolutione circa solem transire, et circa ipsum esse centrum mundi: quo etiam sole immobili permanente, quicquid de motu solis apparet, hoc potiùs in mobilitate terræ verificari, &c.' It must be observed that he lays down a sphere for the fixed stars so distinctly, that his commentator Muler finds it necessary to remind the reader that he does not *name* the spheres of the planets. But we shall presently see that he could not divest himself of the idea that the primitive motions of the planets were such as would be caused by their being fixed in immense crystal spheres which revolve round the sun.

Before proceeding further it will help us here to observe, that Copernicus does not in the smallest degree attempt to answer the mechanical objections to the earth's motion, which were urged with success against his system till the time of Galileo. The laws of motion, as then explained, and as admitted by Copernicus himself, were altogether insufficient to explain why, if the earth moved, a stone should fall directly under the point from which it is dropped. No explanation of such difficulties is given by Copernicus, nor can we find (nor did Delambre find) that they are even alluded to as an element of the question. If the mechanics of Copernicus had been true, the system of Copernicus would have been physically impossible. Now this is an essential element in the character of a discovery, which is materially altered if that which is advanced as true be advanced on false grounds. It is true that fire burns, and it is true that two and two make four; but it is false that two and two make four *because* fire burns. We give no credit to the Pythagoreans, if it be true, as asserted, that they placed the sun in the centre of the planets because they thought fire the most excellent of all things. We may consider the omission of Copernicus in two different lights. The first is, that he saw the mechanical difficulties, but was so struck by the simplicity of his astronomical system that he thought it more probable than the mechanics of his day, and suspected that future researches would produce laws of motion which should allow of the possibility of his system; and thinking thus, he judged it more wise not to enter upon the mechanical question, so as thereby to shock two sets of received opinions at once. This would do honour to his sagacity; but unfortunately, the single sentence above alluded to, the equestrian simile, prevents us from supposing that if he considered the subject mechanically at all, he was other than satisfied with his own conclusion, 'Cum ergo motus circularis sit universorum, partium vero etiam rectus, dicere possumus manere cum recto circularem, sicut cum *ægro* animal.' The word in italics must be a misprint for *equo*, as remarked by Muler. The latter distinctly points out that this is meant to explain the difficulty of a falling stone, and adds, 'Sententiæ hujus veritas dependet ex hypothesi Coperniciana;' that is, the truth of the proof depends upon that of the thing proved. He should have said (and possibly did mean), that upon the truth of this sentence the Copernican hypothesis depends, so far as it was proved by Copernicus himself. Our readers now must begin to have an idea how great an injustice has been done to those who found better reasons for the coexistence of rectilinear and circular motion, by the attachment of the name of Copernicus to the present cosmical system.

The second method by which we may suppose Copernicus to have reconciled difficulties, is the actual assertion made both by himself and Osiander, that the hypothesis of terrestrial motion was nothing *but* an hypothesis, valuable only so far as it explained phenomena, and not considered with reference to absolute truth or falsehood. It is usual to consider the expressions in question entirely as a concession to general opinion, and as intended either to avoid the Inquisition, or to induce those to look into the book who would otherwise have put it aside as anti-Mosaical and heretical. And though there may be some truth in this, we are on the whole inclined to suspect that the hypothetical hypothesis, as we may term it, really did bias the mind of Copernicus much more than has been supposed. We do not at all concede that the interference of ecclesiastical power was as likely in the case of the Prussian priest of 1540, as in that of the Italian layman of 1633. Nothing is more common that to view the middle ages as a whole, without noticing the ebbs and floods of power and opinion. The epoch contained between the last Lateran Council and that of Trent, in which the work of Copernicus was written, printed, and published, was sufficiently occupied by diocesan councils, both against Luther, and on the reformations in discipline of which the necessity began to be perceived. It appears to us far the most likely that the mind of Copernicus must have balanced between the two views we have described, and probably must have inclined different ways at different times.

We now come to the brightest jewel in the crown of Copernicus, the method in which he explained, for the first time and with brilliant success, (so far as *demonstration* went, as before described,) the variation of the seasons, the precession of the equinoxes (book i. cap. 2, book iii., and book vi. cap. 35), and the stations and retrogradations of the planets. The latter point is fully made out, and in the manner now adopted, so far as the *qualities* of the phenomena are concerned: we shall presently see the method of rectifying the *quantities*. With regard to the variation of the seasons, Copernicus explains it rightly, from the continual parallelism of the earth's axis. But he cannot obtain this parallelism from his mechanics. He imagines that if the globe of the earth move round the sun, and also round its own axis, the axis of rotation must always preserve the same inclination to the line joining the centre of the earth and sun: just as when a ball fastened by a string is made to spin, and a conical motion is simultaneously given to the string and ball. It is most evident that he got this idea from the solid crystal spheres. If the earth's axis were fixed in an immense sphere, with which it turned round the sun, and if in the first instance the axis produced would pass through the axis of the sphere, the complete phenomenon of Copernicus would be produced. The earth's axis would then describe a cone yearly. To produce parallelism, Copernicus imagines what we may call an anticonical motion, namely, that the earth's axis is itself endued with such motion, independent of its motion in the sphere, as would, did it act alone, carry the axis round the same cone in a year, but the contrary way. The effect of the two motions is to destroy each other, and the axis remains parallel in all its positions. Then, by supposing the anticonical motion to be a little greater than the direct conical motion, by 50″ in a year, he produces the phenomenon of the precession of the equinoxes. If we consider that even Newton himself, in tracing the effect of the forces which cause the precession, is thought to have misconceived his own laws of motion, it is not at this part of the mechanics of Copernicus that we need express surprise: and this explanation of the cause of the seasons and of the precession, together with that of the stations, &c. of the planets, must always place him among cosmical discoverers of the first order of sagacity.

All that we have hitherto described will explain the mean motions of the solar system, and the mean motions only. To account for all irregularities, Copernicus (hampered with the notion that all motions must be compounded of circular ones) is obliged to introduce a system of epicycles entirely resembling that of Ptolemy, and which will be most conveniently described under the head [Ptolemaic System.] It will surprise many readers to hear that the greater part of the work of Copernicus is taken up with this description of this most essential branch of the real 'Copernican system.' But it must be added that the Copernican epicycles are more successful than the Ptolemaic. The latter were utterly insufficient as a means of *demonstrating* the changes of distance of the planets and earth. The former, founded upon a basis which brought this point not very far from the truth at the outset, made a much nearer approximation to a correct representation of the inequalities. But as the epicyclic system is not now connected with the name of Copernicus, we need pursue this subject no further, satisfied that what we have done will have a tendency to put the reputation of that sagacious investigator in its proper place, and that no mean one, though lower than the one usually assigned to it.

Of the tables of Copernicus, his trigonometrical formulæ, &c., we shall have to speak in their proper places; they are more connected with the sciences they belong to than with his biography.

While Copernicus was in daily expectation of receiving a complete copy of his work from Rheticus, he was seized with hemorrhage, followed by paralysis. The book actually arrived May 23, 1543, and, as Gysius wrote to Rheticus, Copernicus saw it, and touched it, but was too near his end to do more. He died in a few hours after, and was buried in the cathedral to which he belonged.

We copy the following references to sources of information from the 'Bibliog. Astron.' of Lalande, p. 595: Adam, 'Vitæ Phil. Germ.;' Tycho Brahé, 'Orat. de Math.;' Jovius, 'Elog. Doct. Vir.;' Bullialdus, 'Proleg. Astr. Phil.;' Vossius, 'De Sci. Math.;' Crasso, 'Elog. d'Uom. Letter.;' Ghilini, 'Teatro,' tom. ii.; Freherus, tom. ii.; Blount, 'Cens. Cel. Auct.;' Paschius, 'De Invent. Nov. Ant.;' 'Actu Phil.,' part v., p. 884; Zernecke, 'Chronik von Thorn,' 2 ed., Berlin, 1727; 'Pantheon der Deutschen,' 1796; 'Berlin. Monatschrifft,' August, 1792, March, 1793; 'Preussiches Archiv.,' December, 1796; Wieland, 'Teutscher Merkur,' November, 1776. We may here notice that Ghilini asserts an epistle 'De Motu Octavæ Sphæræ' to have been printed; but as Gassendi had never seen it, and we can find no mention of it, we conclude no such epistle was published, though one with that name was certainly written.

COPING, the stone or brick covering of a wall, a term perhaps derived from the Italian *coprire*, to cover. Some think it is derived from the German *kopf*, or Dutch *kop*, the head. Coping-stones are placed on the tops of walls to protect them from the weather. Flat coping is called *parallel coping*, and is used upon inclined surfaces, as on the gables and parapets of houses, and also on the tops of garden and other walls. *Feather-edged* coping has one edge thinner than the other. *Saddle-back* coping is thicker in the middle than at the edges. Coping-stones should project over the walls which they cover, and should have a groove or *throating* underneath the projected part to throw off the water. The coping of Gothic battlements and the walls of churches, castles, and dwellings in the Gothic style of architecture, have a deep throating in the form of a bold cavetto in front, and are sometimes decorated with mouldings. [Battlement.] York stone is much used for parallel coping, and also Portland, but the latter is more expensive and not so durable. Bath stone coping is often used for Gothic works, but it is not calculated to withstand long the constant action of the weather.

COPLEY, JOHN SINGLETON, was born at Boston, in the United States, July 3, 1737. His father, who was of English extraction, resided in Ireland until his removal to America, which took place so immediately before his son was born, that Ireland has claimed him as a native. He was educated in America; and without the aid of instructors, simply by studying from nature in the groups around him and the neighbouring woods, he taught himself to paint. In 1760 he sent a picture of a 'Boy and Tame Squirrel' to the exhibition of the Royal Academy, which was universally admired. By the year 1767 he was in the receipt of a considerable income as a portrait painter, and was well known both by his works and by name to his brother painters on this side of the Atlantic. In 1774 he indulged a long-felt wish to visit Italy, which he reached by way of London. In the following year he returned to London, and established himself in George Street, Hanover Square. In 1777 he was elected an associate of the Roya Academy; and in 1783 he became a member. He died in 1815. One of his children, now Lord Lyndhurst, possesses some of his father's best paintings.

The best known of Copley's works is the 'Death of Lord Chatham,' which includes some valuable portraits. It was engraved by Bartolozzi on a plate of an unusual size, and the engraving was extensively sold. The painter sent an impression to General Washington, and another to John Adams. He painted many historical subjects, some sacred, and not a few illustrating the history of England, particularly the period of the Revolution. Perhaps the most spirited design from his pencil is the death of Major Pierson, a young officer who died in the defence of St. Helier's, in Jersey, against the French, at the moment when his troops gained a victory over an enemy of superior numbers. There is a dryness and stiffness of manner in Copley's paintings generally, which is less observable in this picture. It is among those in the possession of Lord Lyndhurst. (A. Cunningham.)

COPPER is one of the metals with which the Greeks were acquainted, under the name of χαλκός (chalcus): it was used by them, alloyed with tin, for cutting and warlike instruments, before iron was known, or at any rate before it was common.

The word copper is said to be derived from the Island of *Cyprus*.

Copper has a red colour, and is capable of receiving a good polish; when warmed or rubbed it emits a disagreeable smell, and it imparts a nauseous taste: all its preparations are poisonous. Its density varies according to circumstances; Berzelius states that he found the specific gravity of fused copper to be 8·83, the same when drawn into a cylinder of two lines in thickness 8·946, and when laminated 8·958. Copper is malleable both when hot and when cold, and it may be reduced to very thin leaves; it is also very ductile, and may be drawn into fine wire. After iron and platinum it is the most tenacious metal: a wire $\frac{78}{1000}$ of an inch in diameter supports a weight of 302 pounds without breaking; it is extremely sonorous, and is a good conductor of heat and electricity. It melts at a temperature intermediate as to the fusing points of silver and gold, or, according to Professor Daniell, at a temperature equal to about 1196° Fahr. In pure dry air it does not readily tarnish or oxidize; but if the air be moist, by long exposure it is first oxidized and then converted into green carbonate.

This metal is one of those which occurs in the greatest number of places and in the largest quantity. It is found, though not in large proportion compared with the whole quantity actually obtained, in a metallic state, and is either amorphous, crystallized in cubes, octahedrons, or dendritic. Its ores are too numerous to admit of a detailed account, and as a mere catalogue would convey but little information, we shall only mention some of the more important. It occurs combined with sulphur, forming black sulphuret of copper, or vitreous copper ore; but principally with sulphur and iron, forming a double sulphuret, commonly called copper pyrites or yellow copper ore: this constitutes nearly the whole of the ore raised in Cornwall. It is found also combined with oxygen, forming the red, or suboxide of copper, or ruby copper ore, and less frequently it occurs as black oxide. It occurs also in the state of combination with some acids, as blue and green carbonate of copper, phosphate, sulphate, and silicate of copper.

Copper pyrites occurs in the north of Europe, in England, especially in Cornwall, Devonshire, and Anglesey, and in many parts of Asia and Africa, and the American continents.

We shall now give a brief statement of the mode of treating this ore, from an account given by J. H. Vivian, Esq., M. P., and published in the 21st vol. of the 'Annals of Philosophy.

The ores are conveyed from Cornwall and Devonshire to Wales, to be smelted, on account of the supply of fuel in South Wales. By this arrangement the vessels not only carry the smaller quantity of material to the greater, but load back with coal for the use of the engines of the mines.

The principal smelting works are situated on the navigable rivers of Swansea and Neath. The furnaces in which the operations are conducted, are reverberating and of the usual construction; they are of different uses for different purposes. Thus the calcining furnaces or calciners are from seventeen to nineteen feet long, and fourteen to sixteen wide, and the melting furnaces are from eleven to eleven and a half feet long, and seven and a half to eight feet wide; the form of the calciner is hexagonal; the melting furnaces are oval flattened at one end.

The processes are eight in number, and the first is:

The calcination of the ore.—The charge of ore usually put into the calciner weighs about three to three and a half tons; it is distributed equally over the brick bottom of the furnace. The process continues twelve hours, and towards the end of it the heat is as great as the ore will bear without fusion. To prevent this, it is frequently stirred during the operation. When this process is over, the charge is drawn out through holes in the bottom of the calciner, and if it has been well conducted the ore is black and powdery. During the calcination the arsenic is expelled and the sulphur is got rid of in the state both of sulphurous and sulphuric acid, and the copper and iron are both oxidized.

Melting of the calcined ore.—The furnace is charged through an aperture placed on the top of it. When the charge is spread over the bottom of the furnace, the door is put up and well luted. Some slags from the fusion of what is called the waste metal are added, not only on account of the copper they contain, but to assist in the fusion of the ore.

In this operation, unlike the first, the object is to melt the charge, and when this has taken place, the door of the furnace is taken down, and the liquid mass is well *rabbled*, or stirred, to allow the metallic sulphuret to separate from the earthy matter. When the latter flows on the former, it is skimmed off, and this being done, fresh charges of calcined ore are added till the metal collected at the bottom of the furnace is as high as the furnace will admit without flowing out at the door; the tapping-hole is then opened, in the side of the furnace, through which the metal flows into a pit of water. It thus becomes granulated, and collects in a pan, which is raised by a crane.

In this process a great proportion of the earthy matter and iron of the ore is got rid of. The granulated metal generally contains about one-third of copper, or is about four times as rich as the average ore; it now consists chiefly of copper, iron, and sulphur. When the ores are refractory they are rendered more fusible by the addition of fluor spar. In this state it is called *coarse metal.*

The slags obtained in this operation are broken up to examine whether they contain any copper, and if so, they are returned to the smelter to be remelted.

Calcination of the coarse metal.—This operation is conducted precisely in the same manner as the calcination of the ore; the charge is nearly of the same weight; it remains twenty-four hours in the furnace; the great object is to oxidize the iron; the heat during the first six hours should be moderate, and afterwards increased to the end of the operation. This is the *calcined coarse metal.*

Melting of the calcined coarse metal.—This is performed in furnaces similar to the melting furnace. To the calcined metal are added some slags from the last operations in the works which contain some oxide of copper, as likewise pieces of furnace bottom impregnated with metal.

In this operation the oxide of copper in the slags becomes reduced by a portion of the sulphur which combines with the oxygen, and passes off as sulphurous acid gas, while the metal thus reduced enters into combination with the sulphuret; sometimes a little uncalcined ore is added to assist the operation, which it does by the sulphur that it contains.

The metal, after the slag is skimmed off, is either tapped into water or into sand beds, according to the mode of treatment to which it is to be subjected in subsequent operations. In the granulated state it is called fine metal; in the solid form, blue metal, from the colour of its surface. The former method is practised when the metal is to be brought forward by calcination; it then contains about sixty per cent. of copper, and it is called fine metal.

Calcination of the fine metal is performed in the same manner as the calcination of the coarse metal.

Melting of the calcined fine metal.—This is effected in the same manner as the melting of the coarse metal; the resulting product contains eighty to ninety per cent. of copper, and is called coarse copper.

Roasting.—This is chiefly an oxidizing process. The furnaces in which it is performed are called roasters, and are of the same kind as the melting furnaces. The pigs of coarse copper obtained by the last process are put into the furnace and exposed to the action of the air at a high temperature, which is gradually raised to the melting point; by this process the expulsion of volatile matter is completed, and the metals are oxidized; each charge is from twenty-five to thirty hundred weight. The metal is fused towards the end of the operation, which is continued for twelve or twenty-four hours, according to the state of forwardness when filled into the furnace, and is tapped into sand beds. The pigs are then covered with black blisters, in which state the copper is known by the name of blistered copper. In the interior of the pigs the metal has a porous honeycombed appearance, occasioned by the gas liberated during the ebullition which takes place in the sand beds on tapping. It is in this state fit for the refinery, the copper being freed nearly from all the sulphur, iron, and other substances with which it was combined.

Refining or Toughening.—The refining furnace is similar in construction to the melting furnaces, and differs only in the arrangement of the bottom, which is made of sand, and laid with an inclination to the front door instead of to one side, as is the case in those furnaces in which the metal is flowed out. The refined copper is taken out in ladles from a pool formed in the bottom near the front door. The pigs from the roasters are filled into the furnace through a large door in the side. The heat at first is moderate, so as to complete the roasting or oxidizing process, in case the copper should not be quite fine. After the charge is run down, if there is a good heat on the furnace, the front door is taken down, and the slags skimmed off. An assay is then taken out by the refiner with a small ladle, and broken in the vice; and from the general appearance of the metal in and out of the furnace, the state of the fire, &c., he judges whether the toughening process may be proceeded with, and can form some opinion as to the quantity of poles and charcoal requisite to render it malleable, or, as it is termed, to bring it to the *proper pitch.* The copper in this state is what is termed *dry.* It is brittle, of a deep red colour inclining to purple, of an open grain, and a crystalline structure. In the process of toughening, the surface of the metal in the furnace is first well covered with charcoal; a pole, commonly of birch, is then held in the liquid metal, which causes considerable ebullition, owing to the evolution of gaseous matter. This operation of *poling* is continued, with the occasional addition of fresh charcoal, so that the surface of the metal may be kept covered, until, from the assays which the refiner from time to time takes, he perceives the grain, which gradually becomes finer, to be perfectly closed, to assume a silky polished appearance in the assays when half cut through and broken, and to be of a light-red colour. He then makes further trial of its malleability by taking out a small quantity in a ladle and pouring it into an iron mould, and when *set*, beating it out while hot on the anvil with a sledge. If it is soft under the hammer, and does not crack at the edges, he is satisfied as to its malleability, or, as they term it, that it is *in its proper place.* He then directs the men to lade it out, which they do in iron ladles coated with clay, pouring it into pots or moulds of the size required by the manufacturer. The usual size of the cakes for common purposes is 12 inches wide by 18 in length.

The process of refining or toughening copper is a delicate operation, and requires great care and attention on the part of the refiner to keep the metal in the malleable state. Its surface should be kept covered with charcoal, otherwise it will go back between the rounds of lading, in which case fresh poling must be had recourse to: the cakes are allowed to cool in the pot, and others are laded thereon. Overpoling is to be avoided, as the metal is thereby rendered even more brittle than when in the dry state: its colour also becomes a light yellowish-red, and its structure fibrous. When this is found to be the case, or, as they say, it is *gone too far*, the refiner directs the charcoal to be drawn off the surface of the metal, and thus by taking down the side door and exposing the copper to the action of the air, it is brought back to its proper pitch; that is, it again becomes malleable.

Copper for brass-making is granulated, in order that its surface may be increased, and it may thus combine more readily with the zinc or calamine. This is effected by pouring metal from the ladles in which it is taken out of the furnace into a large ladle pierced in the bottom with holes, and supported over a cistern of water. The water may be either hot or cold, according to the form to be given to the metal. When warm, the copper assumes a round form, and is called *bean shot*. When a constant supply of cold water is kept up, the metal has a light ragged appearance, and is called *feathered shot*. The former is the state in which it is prepared for brass wire making. Another form into which copper is cast, chiefly for export to the East Indies, is in pieces of the length of six inches, weighing about eight ounces each: these are called *japan copper*. The copper is dropped from the moulds immediately on its becoming solid into a cistern of cold water, and thus, by a slight oxidation of the metal, the sticks of copper acquire a rich red colour on the surface.

Various important applications are made of copper in the state of sheets or rolled copper. Copper, like most of the unmixed metals, is generally rolled hot, being malleable at all degrees of heat till it approaches its melting point. Most of its alloys with zinc, frequently called spelter, known in commerce by the general term brass, are malleable only when cold, with the exception of one or two lately brought into use, which are extremely malleable at a certain high temperature. Copper for the purpose of rolling leaves the smelting works in cakes about 12 × 18½ inches thick, each weighing about 90 lbs. The cakes are then put into *muffles*, where they are uniformly heated; the degree of temperature depends on the quality of the copper; in general it is something beyond a bright red heat. In this state they undergo the process technically called *breaking down*, which consists in passing them between strong cast-iron cylinders as in the rolling of iron, the rolls being forced nearer together so as to diminish the intermediate space after each passage of the cakes through them. This process is continued until the cake is lengthened about five fold, by which time it has become too cold for further procedure in that stage. It is then cut by strong shears into pieces, called blanks, of the required weight, which are heated in the muffle and rolled out till they are twice as long as broad. Being again heated, they are now doubled, and thus rolled crosswise till they reach the required lengths, though in this process of finishing it becomes necessary frequently to heat them, and when the sheets are thin to roll several thicknesses together. The oxide of copper, which has in process of rolling been pressed in the surface, must now be removed; to effect which each sheet is first dipped into a saline mixture, and then put into the muffle. When red hot it is withdrawn and plunged into cold water, where the scale or oxide is suddenly cooled, and by its contraction is separated from the sheet and falls to the bottom, leaving the surface of the copper clean. This process also softens the sheet, which is now fit to be worked into any form. The only remaining process is that of shearing the edges, which is effected by a pair of circular shears, which, when required, cut both edges at the same time. Copper is sometimes rolled cold after it has undergone the process of breaking down, as above described, in the same manner as brass; it is generally rolled thus when it is needed hard in texture and bright on the surface.

We shall now describe the more important compounds of copper.

Oxygen and copper may be readily made to combine, and in two proportions; when copper is merely heated, scales are formed upon it, which, when removed, are found to consist of a suboxide and protoxide of copper. If these scales be reduced to powder and heated in dilute sulphuric acid, a red powder is left and a blue solution is obtained. This red substance is the suboxide of copper, and is composed of

1 equivalent of oxygen	8
2 equivalents of copper 32 × 2	64
equivalent	72

it is therefore a dioxide.

This oxide exists in nature, and occurs in Cornwall in the form of beautiful transparent crystals of a fine red colour, and is hence frequently called *ruby copper*. This oxide is not soluble in acid unless it acquire additional oxygen by the act of solution Thus it is not acted upon by dilute sulphuric acid either hot or cold; but when heated with the concentrated acid, it is decomposed, sulphurous acid being evolved and oxide of copper formed with the oxygen of the decomposed acid. It undergoes the same change by nitric acid, which it decomposes, and combines with the oxygen of it. In muriatic acid it is soluble, but then becomes a chloride from which water throws down a white subchloride and potash yellow or orange dioxide. With ammonia it forms a colourless solution, which becomes speedily blue by the oxidizement that occurs on exposure to the air. This oxide, it is evident from what has been stated, forms no salt with any acid.

Oxide or protoxide of copper. When the scales which have been described as falling from copper by the application of heat and air, are subjected to a high temperature with access of air in a crucible, the whole quantity is converted into protoxide of copper; or when the blue solution, already mentioned as obtained from the scales, is boiled with excess of potash, first a blue precipitate, which is *hydrate of copper*, is obtained, and in a short time it loses water and becomes black—this is the protoxide of copper, consisting of

1 equivalent of oxygen	8
1 equivalent of copper	32
equivalent	40

It may also be obtained by means of potash from any other salt of copper. The properties of this oxide are that it is black, insoluble in water; it combines with acids in general, and is the base of all the salts of copper. It dissolves in ammonia, to which it imparts a splendid blue colour; but it is insoluble in the fixed alkalis. When the vapour of water is passed over ignited copper, the copper is not oxidized, and no hydrogen is consequently given out; it appears therefore that the affinity of copper for oxygen is not very great. This oxide is is not decomposed by the mere action of heat. It sometimes, though more rarely than the dioxide, occurs in nature. It imparts a green colour to glass generally, but by particular management may render it blue.

Azote, hydrogen, and copper do not combine.

Chlorine and copper unite to form two chlorides; the sub or dichloride may be obtained by exposing copper filings to the action of chlorine gas, not in excess; or by evaporating, with as little contact of air as possible, a solution of dioxide of copper in muriatic acid. It is a yellow, translucent, crystalline compound, which is insoluble in water, but dissolved by muriatic acid, from which water throws down a white precipitate, and potash a yellow one. It is applied to no use: it is composed of

1 equivalent of chlorine	36
2 equivalents of copper	64
equivalent	100

When this is exposed to the air it becomes green, and is probably converted into an oxichloride; the same substance is produced by exposing copper to the action of muriatic acid and the air. It is usually called submuriate of copper; this compound is also found in Peru, and is called the *green sand of Peru*, or *Atacamite*.

Chloride of copper may be formed by dissolving the oxide or protoxide of copper in muriatic acid, when a fine green coloured solution is procured, which by evaporation to dryness at a temperature not exceeding 400° leaves chloride of copper; this compound is yellow, and soluble in water, and composed of

1 equivalent of chlorine	36
1 equivalent of copper	32
equivalent	68

Sulphur and copper combine very readily at a moderate temperature. The compound occurs in nature, and is frequently called *vitreous copper*. It is composed of

1 equivalent of sulphur	16
2 equivalents of copper	64
equivalent	80

It is therefore a disulphuret of copper. It may be prepared artificially by heating a mixture of sulphur and copper. The native compound is black, frequently shining, and crystallizes in six-sided prisms, &c.; it is met with also amorphous. The artificial compound is brittle and brownish-black. When exposed to heat and air the sulphur is expelled and oxide of copper remains. Nitric acid converts it into sulphate of copper; the same effect is produced by exposing the artificial compound to air and moisture.

Sulphuret of copper is obtained by adding sulphuretted hydrogen gas to any salt of the oxide of copper, as the sulphate, nitrate, &c. A black precipitate is thrown down, which contains twice as much sulphur as the last mentioned, or it is composed of

1 equivalent of sulphur	16
1 equivalent of copper	32
equivalent	48

No use is made of this compound; it is converted into sulphate by treatment with nitric acid. It is not acted upon by dilute acids in general.

Bromine and copper.—This compound is in the form of small translucent plates. It is insoluble in water; muriatic acid dissolves without decomposing it; but neither sulphuric nor acetic acid, even when concentrated and boiling, has any action upon it. When heated out of the contact of air, it remains undecomposed; whereas, when the air is present, vapour is emitted, which gives the flame a green colour, and oxide of copper remains in the crucible. It is composed of—

1 equivalent of bromine	78
1 equivalent of copper	32
equivalent	110

Bibromide of copper may be formed by dissolving oxide of copper in hydrobromic acid; it is a deliquescent salt, which crystallizes in yellow needleform crystals. It contains two equivalents of bromine.

Iodine and copper combine to form iodide of copper. The compound is, however, but little known; when an alkaline iodide is poured into a solution of copper, a grey precipitate is obtained, which appears to be a mixture of iodine and iodide of copper.

Fluorine and copper. These substances combine; but little is known respecting the compound. When carbonate of copper is dissolved in hydrofluoric acid, carbonic acid is evolved, and an insoluble compound, which appears to be fluoride of copper, is formed.

Selenium and copper. When sileniuretted hydrogen gas is passed into a solution of copper, black seleniuret of copper is formed and precipitated; when dried, it has a deep grey colour, and is susceptible of a polish. When heated, it loses half of its selenium, and a button of seleniuret of copper remains.

Phosphorus and copper, when heated together, form a fusible white, crystalline, hard, brittle phosphuret. It is best obtained by passing the vapour of phosphorus over copper wire heated to redness. It is a diphosphuret composed of—

1 equivalent of phosphorus	16
2 equivalents of copper	64
equivalent	80

Copper and other metals form *alloys of copper;* those which result from its union with tin and with zinc are the most important. Some of the former have already been noticed under the head of bronze and bell-metal, and of the latter under that of brass. *Tutenag* is said to be an alloy of copper, zinc, and a little iron; and *tombac, Dutch gold, similor, Prince Rupert's metal,* and *Pinchbeck* are alloys containing more copper than exists in common brass. *Mannheim gold* is a peculiar alloy of copper and zinc, which is said to consist of three parts of copper and one part of zinc. The new standard measures made by Mr. Bate were formed from an alloy 57·6 parts copper, 5·9 tin, and 4·8 brass. This was preferred on account of its being less liable to oxidize than brass. *Packfong*, or the white copper of China, is an alloy of copper, nickel, and zinc, now extensively employed in this country under the name of *German silver;* it is nearly as white as silver, and takes a fine polish; it requires great caution in rolling. According to Dumas, that which is used for spoons and forks consists of copper 50, nickel 25, zinc 25; these proportions being slightly varied for different uses. The Chinese packfong, he says, consists of copper 40·4, nickel 31·6, zinc 25·4, iron 2·6 in 100 parts.

Copper and antimony, combined in the proportions 3 parts of the former to 1 part of the latter, is lamellar, brittle, and has a violet colour; but when equal quantities of the metals are used, the compound has not this colour, and it becomes whiter as the proportion of antimony is increased.

Copper and arsenic form a greyish white mixture, with a compact granular texture; it is not applied to any purpose whatever.

Acids and oxide of copper form salts, some of which occur in nature, and others are very extensively used in the arts. Our limits will permit the mention of the more important only.

Acetic acid and copper form two salts; namely, the acetate of copper, sometimes called *distilled verdigris*, and the diacetate of copper, or *common verdigris.* The diacetate was formerly prepared almost exclusively in France, by causing the husks and stalks of the grape after wine-making to ferment in contact with copper plates. It is now prepared in England by more direct processes. This salt, when pure, is in the form of light blue acicular crystals, of a silky lustre; they are decomposed by water into acetate, which remains dissolved, and a subsalt, which is precipitated. It is usually obtained in large masses, which have no crystalline form, having been packed while moist in leather bags. This salt is decomposed by the stronger acids, by the alkalis, and by heat. It is much employed as a pigment, and in hat-making, dyeing black, and several processes in the chemical arts. It consists of—

1 equivalent of acetic acid	51
2 equivalents of oxide of copper	80
6 equivalents of water	54
equivalent	185

Acetate of copper is prepared by dissolving the diacetate in acetic acid; twigs are put into the solution, upon which the salt crystallizes; it is of a beautiful deep green colour, and the form of the crystal is an oblique rhombic prism; it is soluble in five parts of boiling water, and but little soluble in alcohol. When submitted to destructive distillation, it yields very strong acetic acid, with some other products. It is composed of—

1 equivalent of acetic acid	51
1 equivalent of oxide of copper	40
1 equivalent of water	9
equivalent	100

Arsenious and arsenic acid both combine with oxide of copper. The arsenite of copper is employed as a pigment, under the name of mineral or Scheele's green. It is prepared by adding a solution of arsenite of potash to one of sulphate of copper, by which arsenite of copper is formed and precipitated. Arseniate of copper is found in Cornwall in various forms and composition, and constitutes a beautiful series of copper ores. It may be artificially prepared by mixing solutions of arseniate of potash and sulphate of copper.

Carbonic acid and copper combine in two proportions, which may be artificially prepared, and occur in nature. The green carbonate called malachite is found principally in Russia, and is of a fine green colour. It is artificially prepared by mixing hot solutions of sulphate of copper and carbonate of potash. It is composed of—

1 equivalent of carbonic acid	22
2 equivalents of oxide of copper	80
1 equivalent of water	9
equivalent	111

It is used as a pigment under the name of *green verditer;* it is decomposed by the stronger acids and by heat.

Blue carbonate of copper is found in France and Siberia beautifully crystallized, and is obtained artificially by decomposing nitrate of copper. It is of a fine light blue colour, and known by the name of *refiners' verditer.* It is employed as a pigment, especially as a water colour for paper-hangings. It is composed of—

2 equivalents of carbonic acid	44
3 equivalents of oxide of copper	120
1 equivalent of water	9
equivalent	173

It is decomposed in the same way as the green carbonate.]

Nitric acid and copper readily combine; the salt may be prepared either by dissolving the metal or the oxide of copper in the acid; it is a crystalline deliquescent salt, which dissolves readily in water and in alcohol. Much of this salt is formed by the silver refiners by precipitating silver from solution by copper; it is then used for making *blue verditer*. It is composed of—

1 equivalent of nitric acid	54
1 equivalent of oxide of copper	40
equivalent	94

When carbonate of lime is added to the solution, a subnitrate is precipitated.

Phosphoric acid and copper, from phosphate of copper. This salt occurs native in crystals, and may be artificially prepared by mixing nitrate of copper with phosphate of soda. It is a light blue precipitate, insoluble in water, and readily dissolved by acids. There probably exist two or three phosphates. It is not an important salt.

Sulphuric acid and copper form *sulphate of copper, blue vitriol*, or *Roman vitriol*, or *blue copperas*. It is prepared in large quantity for the use of the colour-maker and dyer, and is one of the most useful of the salts of this metal. It is readily prepared by dissolving the oxide in the dilute acid; by evaporation large and beautiful blue crystals are obtained, which have the form of rhombic prisms. This salt is soluble in about four parts of water at 60°, and in two parts at 212°. When heated, it loses the greater part of its water of crystallization, and becomes powdery and white; by a very strong heat the sulphuric acid is expelled, and oxide of copper is left; when solutions of the alkaline carbonates are added to a certain extent, subsulphate of copper is precipitated; and this is used as a pigment. It is composed of—

1 equivalent of sulphuric acid	40
1 equivalent of oxide of copper	40
5 equivalents of water	45
equivalent	125

These are the principal salts of copper; but many more may be prepared. These salts are all either blue or green when combined with water; they are all decomposed by potash and soda, which at first throw down blue hydrate of copper, which, when heat and the alkali are used in excess, becomes black oxide. The soluble salts of copper are all precipitated of a reddish-brown colour by the ferrocyanide of potassium, yield a black sulphuret with hydrosulphuric acid, are soluble in ammonia, and yield a precipitate of metallic copper when iron is put into their solutions.

The uses of copper are so numerous, that it would require a volume to describe them all. It is used for coin, for making boilers and numerous utensils, for covering the bottoms of ships and the tops of houses, and in the construction of voltaic batteries. Its various important alloys are mentioned under the heads of Brass, Bronze, Bell-metal, &c.

Copper, in a metallic state, produces no action in the human system. When in the form of oxide, its action is considerable, though variable, being dependent on the kind and quantity of acid which it may meet with in the stomach; but all its salts occasion peculiar effects, which may be fatal if the dose be large. It is not necessary that the substance should be introduced into the stomach, for the salts of copper act in whatever way they are introduced into the system, and the more energetically, the more directly they enter the blood. The greater the degree of solubility, the more rapidly are the formidable symptoms displayed. The preparations of copper used in medicine are, the sulphate, or blue vitriol, called also blue-stone; the ammoniated sulphate or ammoniuret; and the diacetate, or verdigris. The two former are used internally, the latter rarely; it and the sulphate being applied by surgeons to wounds and sores in particular states.

Sulphate of copper influences powerfully the nervous system, and acts as a tonic and antispasmodic: it has also some astringent properties. In a considerable dose it causes vomiting; in still larger doses it causes purging, accompanied with tenesmus, followed by convulsive agitation of the head, or rigidity amounting to tetanic, laborious respiration, pain and tightness of the head, insensibility, lethargy, and speedy death. In some instances the narcotic symptoms are the first to be displayed, those of irritation succeeding; jaundice, if the patient survive, or yellowness of the corpse is no uncommon occurrence; a fact to be borne in mind as a distinctive mark of poisoning by copper among metals: the same sign, however, occurs in poisoning from aconite and most ranunculaceous plants. If the effect of the poison when copper has been taken has been speedy, few traces of morbid action are found in the intestinal canal; and 'too much reliance ought not to be placed on mere bluish or greenish colouring of the membranes of the stomach; for Orfila and Guersent have both observed that the inside of the stomach as well as its contents may acquire these tints in a very remarkable degree in consequence of natural disease.' (Christison.)

In cases of slow poisoning by copper, such as happen when some of its salts in substance or solution have been taken daily for a considerable time, fatal results follow; and the copper may be detected accumulated in the liver, though not discoverable in any other organ of the body. The circumstance of the copper being carried to the liver explains the frequent occurrence of jaundice, as stated above.

In small medicinal doses, sulphate of copper has been employed in diarrhœa, which, when chronic, it often checks; even in Asiatic cholera it has proved useful. Indeed it seems to check augmented secretion from all mucous surfaces, on which account it may be used in chronic discharges from the urino-genital organs, and also of the lungs, to benefit which last organ it is usually given as an emetic. It may likewise be employed as an emetic in cases of poisoning by narcotic agents, in preference to tartrate of antimony or ipecacuanha, as its action is not preceded by nausea, which promotes the absorption of the poisonous agent.

Its chief internal use, however, is as a tonic and antispasmodic, in many convulsive and nervous diseases, such as epilepsy and chorea. In these last-named diseases the ammoniacal sulphate is often to be preferred, given in the form of pill. Sulphate of copper is however in most frequent use by surgeons as an external application to wounds, when indolent, or filled with the unhealthy kind of granulations termed 'proud flesh:' it is similarly used in some forms of ophthalmia, especially of the inner surfaces of the eyelids.

Diacetate of copper is rarely given internally; but it is the frequent source of accidental or intentional poisoning, when its general effects are nearly the same as those of the sulphate. In the form of a liniment it is of great utility in certain affections of the mouth and gums, applied by means of a camel's-hair brush. Likewise as an ointment to stimulate old and indolent ulcers it is superior to all other means.

Poisoning often results from the formation of verdigris in copper vessels used in cooking, or the more reprehensible practice of putting copper coins into pickles to make them a fine green colour. It seems that copper vessels, if kept clean, are not dangerous, provided whatever is boiled in them (unless of an acid nature, which will always form some dangerous compound,) be not allowed to stand to cool in the vessel, but be instantly poured out. Tinning the interior of copper vessels affords protection so long as the tinning remains entire. In case of poisoning, the best antidotes are whites of eggs, milk, or wheat flour; ferrocyanate of potass, or iron filings in gum-water, may be given; sugar or any syrup is useful. But liver of sulphur should never be given, and least of all should vinegar.

COPPER, STATISTICS OF. No effective attempt has ever been made to ascertain the actual productiveness of the mines in this country, and all that is hitherto known on that subject is derived from partial inquiries of individuals. By this means a tolerably accurate account has been taken of the produce of the copper mines in Cornwall, reaching back to 1771, with the exception of a few intermediate years, the returns of which are wanting. Since 1821 similar accounts have been procured of the produce of other mines in the United Kingdom. The average annual produce of the Cornish mines at different periods between 1771 and 1820, was as follows: 1771 to 1775, 3450 tons; 1776 to 1780, 3310 tons; 1781 to 1785, 3990 tons; 1796 to to 1800, 5174 tons; 1801 to 1805, 5544 tons; 1806 to 1810, 6575 tons; 1811 to 1815, 7181 tons; 1816 to 1820, 7018 tons. Since then the annual produce has been as follows:—

Years.	Copper produced from Ores sold in Cornwall.	Copper produced from ores sold at Swansea.	Produce of Devonshire and Staffordshire.	Produce of Isle of Anglesey.	Total.
	Tons.	Tons.	Tons.	Tons.	Tons.
1821	8,515	344	871	558	10,288
1822	9,140	388	716	774	11,018
1823	7,927	353	694	705	9,679
1824	7,823	605	654	623	9,705
1825	8,226	729	667	736	10,358
1826	9,026	668	615	784	11,093
1827	10,311	772	562	681	12,326
1828	9,921	977	533	757	12,188
1829	9,656	1,221	454	726	12,057
1830	10,748	1,196	510	778	13,232
1831	12,044	1,240	486	915	14,685
1832	11,947	1,320	400	783	14,450
1833	11,191	1,158	406	505	13,260
1834	11,224	1,580	538	700	14,042
1835	12,270	2,832			

The copper yielded by the British mines being more than sufficient for the use of the kingdom, a considerable quantity is exported every year, both in its unwrought and in a manufactured state. The exports since 1820 have been:

Years.	Unwrought.	Coin.	Sheets, nails, &c.	Wire.	Other sorts of wrought copper.	Total quantity exported.
	cwts.	cwts.	cwts.	cwts.	cwts.	cwts.
1820	41,155	10	58,121	8	22,663	121,958
1821	34,543	155	66,676	21	24,035	125,431
1822	25,829		65,070	40	22,731	113,671
1823	24,082	802	56,146	98	25,387	106,516
1824	19,209	95	62,920	292	23,580	106,096
1825	10	2134	51,437	40	25,002	78,624
1826	2,604	1807	65,264	11	26,307	95,994
1827	26,583	1450	74,943	8	40,439	143,424
1828	21,591	1150	52,412	71	48,897	124,121
1829	52,978	15	59,871	13	46,643	159,521
1830	59,722	640	66,331	16	56,443	183,154
1831	67,200	96	70,477	149	32,690	170,613
1832	77,497	2	79,944	13	37,155	194,612
1833	47,887	15	91,366	16	16,947	156,233
1834	81,978		81,363	44	14,344	177,731
1835	63,252	·	103,433	56	15,197	182,225

In the accounts of exports of English produce and manufactures exported, the Custom House statements include brass and copper manufactures together; the total quantity and declared value of these shipments in each year, from 1827 to 1835, have been as follows:

	cwts.	Decl. Value.		cwts.	Decl. Value.
1827	147,222	786,955*l*.	1832	213,482	916,563*l*.
1828	128,106	678,786*l*.	1833	192,974	884,149*l*.
1829	161,241	812,366*l*.	1834	205,960	961,823*l*.
1830	189,592	867,344*l*.	1835	242,095	1,094,749*l*.
1831	181,951	803,124*l*.			

The principal shipments in 1835 were made to the following countries, viz.: India, 73,377 cwts., 316,120*l*.; France, 67,832 cwts., 298,903*l*.; United States of America, 35,626 cwts., 166,060*l*.; Netherlands, 16,409 cwts., 75,027*l*.; Brazil, 8265 cwts., 39,429*l*.; Italy, 8106 cwts., 35,902*l*.; British West Indies, 6080 cwts., 32,393*l*.; Foreign West Indies, 4595 cwts., 21,554*l*.; and British North American Colonies, 2571 cwts., 12,792*l*.

Within the last few years a considerable quantity of copper ore has been brought to England for the purpose of its being smelted and re-exported in the metallic state. These importations, which have come chiefly from Colombia and Chile, have been, 1825, 2 cwts.; 1826, 1297; 1827, 659; 1828, 6693; 1829, 24,258; 1830, 28,733; 1831, 50,919; 1832, 79,115; 1833, 118,632; 1834, 139,740; 1835, 278,900. (*Tables of Revenue, Population, Commerce, &c. of the United Kingdom, compiled at the Board of Trade*, parts 3, 4, and 5.)

COPPER, ALLOYS OF. [COPPER.]

COPPER, ORES OF. [COPPER.]

COPPER-NICKEL. [NICKEL.]

COPPER-PLATE. [ENGRAVING.]

COPPER-MINE RIVER is a river in North America, which falls into the Arctic Ocean. It rises in a rocky country, near 65° N. lat. and 112° W. long., where a series of lakes unite and form the river. The most southern of these lakes is Lake Providence (about 64° 50′ N. lat.). The river first runs nearly due north, until it has passed 66° 30′ N. lat., when it turns west and flows along the foot of a rocky, but not high chain of mountains. Having attained 116° 30′ W. long. it turns abruptly north, and breaking through the mountains continues its course in a northern direction to its mouth 65°50′ N. lat., and a few minutes east of 116° W. long. Its whole course may be about 300 miles. It contains numerous rapids, but none which form insuperable difficulties to canoes and boats which descend the river. The most difficult part is the Bloody Falls, about 10 miles from the mouth. Hearne discovered the mouth of this river in 1771, and it was the first place on the coast of the Arctic Sea of America which was visited by Europeans. Sir J. Franklin descended the greatest part of the river in his first journey. (Franklin and Richardson.)

COPPERAS. There are three metallic salts which are occasionally called copperas, as sulphate of copper (blue copperas), sulphate of iron (green copperas), and sulphate of zinc (white copperas).

COPPICE, a wood or plantation of various kinds of trees, which shoot up from the root when cut down, and which are periodically cut down before they acquire any considerable size. The most common trees planted or used for this purpose are the oak, the chestnut, the maple, the birch, the ash, and the willow. The hazel and the alder are also frequently planted in coppice, the former in dry and chalky soils, the latter in moist and marshy situations. Timber trees are generally allowed to grow in coppice, or more properly the coppice is the underwood where timber is the principal object. There is a doubt, however, whether it is judicious to allow many trees to stand where there is a ready sale for coppice wood. The quick return of the latter overbalances the greater price of old timber. In consequence of this opinion, large trees fit for ship-building, which require a long time to arrive at the required size, are become very scarce; and many woods, once thickly studded with majestic trees, are reduced to mere coppice wood. The value of a well-managed coppice is considerable where the produce can be readily manufactured into useful articles, and carried to a good market. Ash hoops, hop-poles, chestnut gate-hurdles, and sheep-hurdles are the principal articles manufactured or prepared in a newly-cut coppice. What is of no use for these purposes is made into faggots for fuel, where this is scarce, or converted into charcoal, which is more easily transported. A good coppice will bear to be cut down every eight or nine years, and will thus be worth, according to situation, from 6*l*. to 15*l*. per acre, or even more, when sold to those who undertake to cut and prepare the wood.

Little attention is generally paid to the coppice, except when it is fit to be cut, but this is a great mistake: with a little attention a coppice may be doubled in value in a few years. It should be carefully drained where the water has not a ready outlet. Where the most profitable kinds of wood are deficient fresh plants should be supplied. The whole should be kept well stocked, but not overstocked; and the pruning-knife should be used where it appears necessary, especially where hop-poles are in request, which usually bear a good price. Hop-poles require a longer time to attain the proper size, and more room to grow. For this purpose the coppice may be thinned out, without being entirely cut down. When a coppice is cut, attention must be paid to the manner in which the poles and rods are cut off from the stem. They should be divided by a clean slanting cut with a very sharp axe or bill-hook, so as not to shatter the stump which is left. The wound will then soon heal over, and the stump will not be injured by the wet and decay, as is too often the case. When fresh ground is planted for a coppice, it should always be previously trenched and drained. The extra expense of this will soon be repaid. Scotch firs may be planted at first as nurses and shelter to the oaks and other forest trees. In seven or eight years the firs will have acquired a considerable height, and may be thinned out or cut down: they never shoot again from the root. The other trees may be left to grow a few years longer before they are cut down. After the first cutting, attention must be paid to the stumps and all superfluous shoots removed. In seven or eight years a thick coppice will be formed, which will increase in value every time it is cut, and will produce a very good annual rent for land which would not have been profitable in cultivation, either as pasture or arable farms. The annual expense of a coppice is trifling, and the regular returns are certain and profitable. When a portion of coppice is cut every year, so as to have a regular rotation, the income is as regular as that of any other part of an estate. A proportion of coppice on an estate is essential to the production of game and to its preservation.

The ground most favourable for coppice is that which is too steep or rocky for cultivation, and where the climate will not allow of the vine. Where the land is flat, and can be well drained, arable farms will always be most profitable, unless in some poor sandy soils, where corn will not grow without extraordinary manuring, while the roots of some kinds of trees will sink to a great depth and find there the nourishment necessary to their growth. In such sandy soils the birch, the maple, and the acacia sometimes grow luxuriantly, when the grass on the surface scarcely shows signs of vegetation. On wet and boggy soils the willow and the alder are almost the only trees that will thrive. Whoever plants a coppice must be well acquainted with the soil to a considerable depth, and must choose his plants accordingly.

COPT, the name given to the Christian descendants of the antient Egyptians. It is correctly pronounced either Ckoobt or Ckibt, and it is generally believed that the name is derived from Coptos, once a great city in Upper Egypt, now called Ckooft or Gooft, to which, during their persecution by the Roman emperors, many of the Egyptian Christians retired. They are not an unmixed race, their ancestors in the earlier ages of Christianity having intermarried with Greeks, Nubians, and Abyssinians. The secession of the early Christians of Egypt from the Church of Constantinople occasioned bitter enmities to spring up between them and the Greeks, on which account they suffered so much persecution, that they united with the Arab invaders of their country to expel the Greeks; but though their revenge was gratified, they were compelled to bow to a heavier yoke. With the exception of a small proportion who profess the Romish or the Greek faith, the Copts are Christians of the sect called Jacobites, Eutychians, Monophysites, and Monothelites, whose creed was condemned by the council of Chalcedon A.D. 451. The number of churches and convents in ruins prove that the Copts were once far more numerous than at present: they do not now compose more than one-fourteenth part of the population of Egypt, their number not exceeding 150,000, about 10,000 of whom reside at Cairo. Conversions to the Mohammedan faith, and intermarriages with the Moslems, have occasioned this decrease in their numbers; to which may be added the persecutions which they endured from their Arabic invaders and subsequent rulers. They were forced to adopt distinctions of dress, and they still wear a turban of a black or blue, or a greyish or light brown colour, in contradistinction to the red or white turban. The distinction is generally carefully observed in the towns, but less so in the villages. Under the dominion of the present Báshaw of Egypt, the Copts are not now the despised race they once were: some of them have even been raised to the rank of Beys. The male adults pay a tribute, besides the income tax which they pay in common with the rest of the inhabitants; but they are exempt from military service. This immunity is the result of Moslem prejudice.

In some parts of Upper Egypt there are villages exclusively inhabited by the Copts, and in every village of moderate size is a Mo'al'lim (a title given to all Copts except those of the poor class or peasants), who keeps the register of the taxes. Most of the Copts in Cairo are employed as secretaries and accountants, or tradesmen; they are chiefly engaged in the government offices; and as merchants, goldsmiths, silversmiths, jewellers, architects, builders, and carpenters, they are generally considered more skilful than the Moslems. In the villages they are employed in agriculture, like the rest of the peasantry. The patriarch, or head of the Coptic church, judges petty causes among his people in the metropolis, and the inferior clergy do the same in other places; but an appeal may be made to the cadi. A Moslem aggrieved by a Copt may demand justice either from the patriarch or cadi, but a Copt who seeks redress from a Moslem must apply to the cadi. The Copts are somewhat under the middle size. They are extremely bigoted, and bear a bitter hatred to all other Christians; they are of a sullen temper, extremely avaricious, great dissemblers, ignorant, and faithless. In their habits they scarcely differ from their fellow-countrymen. Their dress, with the exceptions already noticed, is similar. The women veil their faces, according to the custom of the country. The Copts frequently indulge in excessive drinking; but in their meals, their mode of eating, the manner in which they pass their hours of leisure, which is chiefly in smoking their pipes and drinking coffee, they resemble the other inhabitants of the country.

The Coptic language is now understood by few persons, and the Arabic being adopted in its stead, it may be considered a dead language. There are numerous schools, but for boys only; very few females among them can read, and those have been instructed at home. The boys are taught the Psalms of David, the Gospels, and the Apostolical Epistles, in Arabic; and then the Gospels and Epistles in Coptic. The antient language is not understood grammatically; and there are scarcely any who can do more than repeat what they have committed to memory of the Scriptures and Liturgy. The Coptic fell gradually into disuse after the Arab conquest; in Lower Egypt the inhabitants had ceased to speak and to understand it before the tenth century, but in Upper Egypt it lingered several centuries longer. All the Copts who have been instructed at school still pray, both in the church and in private, in Coptic; and the Scriptures are always read in the churches in that language; but they are explained from books in Arabic. The British and Foreign Bible Society has printed the Psalter and Gospels in Coptic and Arabic.

The Coptic hierarchy consists of a patriarch, a metropolitan of the Abyssinians, bishops, arch-priests, priests, deacons, and monks. The patriarch is styled 'Patriarch of Alexandria,' but generally resides in Cairo. He is usually chosen by lot, and always from several monks of the convent of St. Anthony, in the Eastern Desert, who are nominated by the superior. He continues to observe the monastic regulations, one of which is to remain unmarried. The metropolitan of Abyssinia, who always resides within his diocese, is appointed by the patriarch, and retains his office for life. The number of bishops is twelve, who are generally chosen from the monastic order. The arch-priests are numerous, and are selected from among the priests. The priests are required to be of the age of thirty-three years at the least, and are not permitted to marry, though they may have married before taking the priesthood; but if the wife dies they cannot marry again; and the widow of a priest is not allowed to marry a second husband. The priests are supported only by alms and by what they obtain by their own industry. A deacon must be either a person unmarried, or have been only once married to a virgin bride. By taking a second wife he loses his office. The monks undergo a severe novitiate, and take the vow of celibacy. The churches contain ill-executed and gaudy pictures of various saints, but no images are admitted. The number of Coptic churches and convents is said to amount to 146, but the former are few in comparison with the latter. The form of service is not characterized by much solemnity, and the conduct of the priests is often somewhat indecorous. Baptism is practised under a belief that if the ceremony be omitted the child will be blind in the next world. The children are generally circumcised; but in Cairo the custom is less strictly observed than in other parts of the country. Confession is required of all members of the Coptic church, and is indispensable before receiving the Lord's supper. Wednesday and Friday are observed as fast-days, except during the fifty days immediately following the Great Fast. The seven great festivals are as follows:—the Nativity of Christ, Baptism, the Annunciation, Palm Sunday, Easter, the Ascension, and Whit-Sunday. The Copts are not allowed by their church to intermarry with persons of any other sect.

The most recent notice of this people (from whence the above statements are taken) is contained in the second volume of *An Account of the Manners and Customs of the Modern Egyptians, written in Egypt during the years* 1833-34 and 1835, by Edward William Lane; 2 vols., London, 1836.

COPTIC LANGUAGE. We designate by the term Coptic the language spoken and written by the inhabitants of Egypt since the introduction of the Christian religion into that country; and we distinguish it from the more antient Egyptian language, which was in use under the Pharaohs and the Ptolemies. The origin of the word *Copt* is doubtful; some have derived it from the name of the city Coptus: we are inclined to recognise in *Copt* the main part of the antient name of the country Αἰγυπτος. The name *Copts* seems to have been used as the common designation of the Christians in Egypt from the time of the Emperor Heraclius, when the patriarch Benjamin was permitted to return from his exile in the Thebaïs (about A.D. 644) and to resume his functions as a bishop at Alexandria. (Le Quien, *Oriens Christianus*, ii. 481.) What was the relation of the antient to the more recent language of Egypt, we are as yet unable to determine, as our information respecting the former is very imperfect. From the analogy however of other languages, the successive changes of which can be traced with tolerable accuracy, we are warranted in supposing that the old Egyptian language bore a relation to the Coptic, similar to that which the Latin does to the Italian, the Zend to the modern Persian, or the Sanscrit to many of the vernacular dialects now spoken in India. Though we cannot here support the assertion by any direct evidence, we may consider it as an established fact, that the antient Egyptians possessed an extensive written literature, besides the monumental inscriptions which still exist. It is by no means probable, that the conquest of Egypt by Cambyses, or the period of Persian dominion which followed that event, should have materially injured the literature of the country; and the subsequent dynasty of the Ptolemies seems to have encouraged rather than to have checked the progress of literature in Egypt. Plutarch tells us (*Vit. Anton.*, c. 27), that Cleopatra spoke several barbaric languages fluently, and though he does not expressly mention the Egyptian, there can hardly be a doubt that it was among the number. Egypt lost much of its consequence when it became a Roman province; and when Alexandria ceased to be a royal residence, arts and literature would naturally fall into decay. Another cause which proved fatal to Egyptian literature was the early introduction of Christianity into Egypt. This event which contributed to extend the study of Greek literature and the use of the Greek language, at the same time deprived the antient literature of the country, as chiefly connected with the old religion, of the better part of its interest. Nor have intentional measures for destroying Egyptian books been wanting. The Emperor Severus collected as many of the Egyptian writings relative to the mysteries of the priests as he could obtain, and buried them in the tomb of Alexander (*Dion. Cass.*, lxxv., c. 13); and Diocletian ordered all books on alchemy to be destroyed, from an apprehension that by the cultivation of that science the Egyptians might again become wealthy, and thus find means to shake off their allegiance to the Roman empire. (Suidas, v. *χημεία* and *Διοκλητίανος*.) Notwithstanding these unfavourable circumstances, the language of the country continued in ordinary use, particularly in the interior provinces. Many hermits in the desert of Thebaïs, and many bishops of Upper and Lower Egypt, knew no other language; and the Egyptian, or as it is more appropriately called during these later times, the Coptic language survived for seven or eight centuries after the conquest of Egypt by the Arabs. We cannot be surprised if at last it entirely disappeared. Vexations of all kinds, religious persecutions, banishments, massacres, and devastations by fire and sword, had from century to century thinned the native population of the country, which had in the same proportion been replenished by settlers from different Arabic tribes of Africa and Asia. In the same manner the Coptic language gradually gave way to the Arabic, which is now the language generally in use throughout Egypt.

The literature extant in the Coptic language is by no means rich. The only part of any intrinsic value seem to be the Coptic translations of the Bible, probably made towards the close of the third and in the beginning of the fourth century, and following, as far as the Old Testament is concerned, the Septuagint version, the readings of which, as well as those of the Alexandrine text of the New Testament, they may serve to determine. Besides these, there exist Coptic translations of sermons from the Greek fathers, fragments of the decrees of councils, likewise generally translated from the Greek, liturgies, acts of martyrs, original mystic treatises on ethics, with numerous examples from the lives of pious hermits, and translations from the Greek of some apocryphal books of the New Testament. Coptic literature offers little or nothing of sufficient interest in itself to make the study of the Coptic language attractive; and, except its use in biblical criticism, its study is of importance only as furnishing the only means by which the inquiry into the hieroglyphic records of antient Egypt may with any chance of success be approached.

Such as we find it, the Coptic language exhibits evident traces of the fate of the country in which it was spoken. Under the Ptolemies, and afterwards under the Romans, new forms of government and administration were introduced into Egypt; and the inhabitants necessarily borrowed from their conquerors the names of public offices and other terms relating to political matters. The Coptic language received a further supply of foreign words in consequence of the introduction of Christianity. A great number of Greek words were retained in the Coptic versions, partly it seems from an apprehension of profaning the Christian doctrine by venturing to translate expressions deemed peculiarly holy in the Greek original text; but doubtless, in a great measure, also from ignorance or laziness, or from a desire to display learning by the use of Greek words. It has been remarked, that the proportion of Greek expressions is not the same in all Coptic writings; and that only a few occur, for which equivalents might not be found among the genuine Coptic words.

It is well known that the antient Egyptians, besides the hieroglyphics, possessed an alphabet or syllabic system of writing of their own. In the modern Coptic we find the Greek alphabet employed, with eight new letters added to it, to express certain articulations peculiar to the Copts. It is uncertain at what period the Greek alphabet came into use.

Athanasius, bishop of Kous, in an Arabic treatise on the grammar of the Coptic language, a manuscript of which is preserved in the Royal Library at Paris, informs us that there were three dialects of Coptic; namely, the dialect of Misr or Upper Egypt, commonly called the Sahidic; the Bahiric, so denominated from Bahirah, or Lower Egypt, and usually called the Memphitic; and the Bashmuric, spoken in the district of Bashmur, in the Delta. In the Bahiric, or Memphitic dialect, as well as in the Sahidic, we possess manuscripts of nearly the whole of the Bible and of the services of the Coptic church, besides some other less important works; but in the Bashmuric dialect only a few fragments have hitherto been discovered and published. The character common to all these dialects is that of a language which, having lost its original power of expressing by grammatical inflection the relations of notions in sentences, has, like most other modern languages, resorted to particles and auxiliary words to supply that deficiency. The precision with which these auxiliary words are employed, and the extent to which they can be combined in forming derivative words, are remarkable, and may well be compared with the use of letters and other symbols in an algebraical formula. The plural of nouns is distinguished from the singular by a monosyllabic prefix: the genders of substantives are seldom marked by a peculiar termination, but are determined either by the article, or by the addition of a word implying 'male' and 'female.' There are no terminations of case; and all changes of declension must be expressed by means of particles. There is a definite and an indefinite article. The definite article has in the singular distinct forms for the masculine and feminine genders, but does not distinguish the gender in the plural; the indefinite article admits of a distinction of number only. The degrees of comparison are expressed by subjoining auxiliary words to the adjective. The personal pronouns are almost the only part of speech that has preserved some traces of inflection: besides these, the Coptic has separate forms for the possessive, the demonstrative, the relative, and the interrogative pronouns, and it has pronominal suffixes and insertions (infixes) which are applied to nominal and verbal inflexions. Ordinal numbers are formed by prefixing various auxiliary words to the cardinal numbers. The verb has only an active voice, and the passive must be expressed by circumlocution, usually by the third person of the plural (as in Latin, *ferunt = fertur*, or in English, *they say = it is said.*) The imperative generally exhibits the root of the verb in its pure state. The conjugation of verbs is accomplished by adding pronominal prefixes to the root, which vary to a certain extent in the different tenses; if a verb in the third person singular is preceded by a relative pronoun, its pronominal prefix is usually dropped; there are no participles in the strict sense of that term. The number of prepositions in the Coptic language is considerable.

Of the three dialects, the Memphitic, Sahidic, and Bashmuric, the first appears to be the most polished. The Sahidic has admitted a greater number of Greek expressions. Words which in Memphitic end in *i*, have in Sahidic *e* for their termination. The Sahidic substitutes the sound *h* for the Memphitic *kh*, and the tenues *π*, *κ*, *τ*, for the aspiratæ *θ*, *χ*, *ϑ*, also sometimes *oo* for *ω*, and *sh* for *j*. The Bashmuric agrees with the Sahidic in preferring the tenues *π*, *κ*, *τ*, to the corresponding aspiratæ, and *h* to *kh*; moreover, it substitutes the vowel *a* for the Memphitic *o*, and *e* for the Memphitic *a*, *ei* often for *i*, *au* for *ov*, *b* for *f*, and particularly *l* for *r*.

(Henry Tattam, *A Compendious Grammar of the*

Egyptian Language, London, 1830, 8vo., and *Lexicon Ægyptiaco-Latinum*, Oxford, 1835, 8vo.; Am. Peyron, *Lexicon Linguæ Copticæ*, Turin, 1835, 4to.; Quatremère, *Récherches Critiques et Historiques sur la Langue et la Littérature de l'Egypte*, Paris, 1808, 8vo.)

CO'PULA. In logic the word copula means the term which connects the subject with its predicate, as in the sentences 'I *am* a Christian,' and 'the tree *is* green,' the expressions 'I' and 'tree' respectively denote the subject, and the verbs 'am' and 'is' serve for the copula.

Philosophers have endeavoured to explain how the copula effects by its interposition one judgment of two ideas, and forms it into a whole. The erroneous modern theories of philosophers otherwise celebrated, such as Kant and Fichte, on this obscure part of metaphysics, greatly influenced the whole of their systems. The following remarks will be found calculated to elucidate this interesting topic.

Knowledge and science consist in the transferring of the truth in nature (in the universe, including the mind and even what is logically possible) to the sphere of human perception; and the whole universe may thus be converted into a countless number of real and lasting impressions. To effect this there must be faculties as numerous as there are classes of truth in nature. Of the latter there is, 1st, the truth of the *identity* of things; every thing resembles and corresponds to itself. This appears so plain that it might be deemed superfluous to mention it, the contrary being indeed impossible. But such is the case in every instance of truth, though each particular instance is not so apparent as this fundamental axiom of A = A. 2ndly, The truth of *unity* in the variety of things—things differ in their accidents, but are substantially the same; for instance, all trees are comprised under the same idea of trees, but they differ in their accidents, such as leaves, flowers, fruits, &c. 3rdly, The truth of *synthesis* of substance and accident—accidents are found closely blended with substance; for instance, in a mineral we cannot separate its colour, gravity, crystalline form, taste, &c.; we cannot put the substance in one place and the accidents in another. 4thly, The truth of *cause* and *effect*—each effect has its cause. 5thly, The truth of *relations of aptness* and *progress* in nature. 6thly, The truth that there exists in nature the *infinitely small*. 7thly, The truth that in nature there is the *infinitely great*. First existed nature with its truth; next creatures existed, and received their faculties of perceiving certain descriptions of truth. Plants are destitute of those faculties; animals in general possess two; those animals which form the transition to man have three; and man has five. In the Deity alone can the whole seven be united.

The first faculty (of perceiving the identity of things) is that of *consciousness* in its general acceptation. It grows into memory, when the brain is developed. (Imagination or phantasy arises from spontaneity, and has no truth in nature corresponding to itself; it is the faculty of blending what is merely probable, and its product is art.) The second faculty is that of *abstraction*, by which unity is perceived in the variety of things: it is found in all animals that have a brain. 3rdly, The faculty of *relation* (intellect), effecting by means of the copula a judgment, in which substance and accidence (in logic called subject and predicate) are connected. As mysterious as this connection is in nature, so mysterious is the copula: the instrument by which the process is performed is the brain. The fourth faculty is that of *drawing conclusions*, or of forming from two judgments (A is B, B is C) a third (C is A). This faculty leads to a communicative language; man only possesses it, and therefore he only, even when deaf and dumb, is capable of speaking. This faculty forms the solitary and certainly important difference between man and the superior animals which form the transition to man. By means of this faculty, man readily attains the fifth, namely, that of discovering *the relation of aptness in nature*; these relations are *ideas*, whence this faculty is called the faculty of *idealizing*. The seventh faculty, of forming an idea of the *infinitely great*, can be attributed to an Almighty God alone. In opposition to what we have explained, the system of Kant asserts, that we cannot know whether or not the truth referred to exists in nature, which we construe merely from our intuitive and mental powers, and which therefore may turn out to be different from what it appears to us.

COPYHOLD, a term in English law applied to lands held by what is called tenure by copy of court roll, the nature of which is thus described by Littleton (§ 73, 4, 5), 'Tenant by copy of court roll is as if a man be seised of a manor, within which manor there is a custom which hath been used time out of mind of man, that certain tenants within the same manor have used to have lands and tenements to hold to them and their heirs in fee-simple or fee-tail, or for term of life, at the will of the lord, according to the custom of the same manor. And such a tenant may not alien his land by deed, for then the lord may enter as into a thing forfeited unto him. But if he will alien his land to another, it behoveth him after the custom to surrender the tenements in court into the hands of the lord to the use of him that shall have the estate. And these tenants are called tenants by copy of court roll, because they have no other evidence concerning their tenements, but only the copies of court rolls.' From this it appears that the title to copyhold lands is not only modified but altogether constituted by custom; subject to the estates in them which the custom confers they are held by the lord under the common law as part of the demesnes of his manor. For these customary estates were in their origin mere tenancies at will, though by long indulgence they have in many instances acquired the character of a permanent inheritance descendible (except where otherwise modified by custom) according to the rules of the common law; and as tenancies at will they continue to be considered in all questions relating to the *legal* as distinguished from the customary property in the land.

The origin of copyholds is involved in great obscurity. The opinion generally adopted among our lawyers and antiquarians, and supported by the authority of Littleton, Coke, Sir Martin Wright, and Mr. Justice Blackstone, is, that copyholders have gradually arisen out of the villeins or tenants in villeinage who composed the mass of the agricultural population of England for some centuries after the Norman conquest, through the commutation of base services into specific rents either in money or money's-worth. (See Co. Litt., 58 a—61 a; Blackstone's *Comm.*, ii., p. 92; Wright *on Tenures*, 3rd edit., p. 215.) See also Hallam's *Middle Ages*, vol. iii., p. 254. [VILLEINAGE.]

Although the revolution in the condition of these classes of persons was accomplished gradually, it seems in the middle of the 13th century to have begun to assume a more decided character. There are proofs of as early a date as the reign of Henry III. of a limitation of the services of villeins to certain specified acts which were recorded in the lord's book. The descendants of persons so privileged began to claim a customary right to be entered on the court roll on the same terms as their predecessors, and, in process of time, prevailed so far as to obtain a copy of the roll for their security. It is said in the year-book of the 42nd of Edw. III. to be 'admitted for clear law that if the customary tenant or copyholder did not perform his services the lord might seize his land as forfeited,' which seems to imply a permanent interest in the copyholder, so long as he performed the services. This view of the law is confirmed by Britton in a passage cited by Lord Coke (Co. Litt., 61 a) and was adopted by the judges in Edward IV.'s time, who held that a copyholder might maintain an action of trespass against the lord for dispossession.

The two great essentials of copyhold tenure, according to Blackstone, are: 1. That lands be parcel of and situate within that manor under which they are held; and 2. That they have been demised or demisable by copy of court roll immemorially. 'For immemorial custom, says that author, ii., p. 96, is the life of all tenures by copy; so that no new copyhold can, strictly speaking, be granted at this day.'

The burdens to which a copyhold tenure is liable in common with free tenures, are fealty, services, reliefs, and escheats; besides which it has certain liabilities peculiar to itself in the shape of heriots and fines. A heriot is the render of the best beast or other chattel (as the custom may be) to the lord on the death of a tenant.

Of fines, some are due on the death of a tenant and others on the alienation of the land; they are sometimes fixed by the custom, sometimes arbitrary; but in the latter case it is an established rule of law that the lord cannot demand by way of fine upon the descent or alienation of the land more than the amount of two years improved value of the property, after deduction of the quit-rents to which it is liable. The ordinary mode of alienating a copyhold estate in fee-simple is by *surrender and admittance*, which is effected in the following manner:—The copyholder appears in court and professes to surrender or deliver up his land to the lord (either in person, or which is more usual, as represented by his steward), expressing the surrender to be to the use of A, and his heirs; and thereupon A is *admitted* tenant of the land to hold it to him and his heirs at the will of the lord according to the custom of the manor. He then pays a fine, and also (if required) does fealty. All these circumstances, or at least the surrender and admittance are entered on the court rolls; and the new tenant, paying his fees to the steward, receives a copy of this fundamental document of his title. Surrenders are made in various forms, as by the delivery of a rod, glove, or other symbol, to the steward or other person taking the surrender. Surrenders may also be made to the lord in person out of court; to the steward; and by special custom to the lord's bailiff; to two or three copyholders, or into the hands of a tenant in the presence of other persons. But when a surrender is taken out of court it must be presented by the homage or jury of copyholders at the next general court, except where a special custom authorizes a presentment at some other court. Admittances also may be made out of court and even out of the manor.

The words in the admittance 'to hold at the will of the lord,' are characteristic of those customary estates to which the term copyhold is in ordinary legal language exclusively appropriated, in contradistinction to what are sometimes called 'customary freeholds' (which estates are very common in the north of England), and antient demesne lands. These are all included under the term copyhold in the statute 12 Car. II. c. 24, which abolished all the old tenures in England except common soccage, copyhold, and some other specified tenures. Though customary freeholds and antient demesne lands for the most part pass by surrender and admittance, the admittance is expressed to be 'to hold according to the custom of the manor.'

The Statutes of Wills (32 Henry VIII. c. 1, and 34 and 35 Henry VIII. c. 5) do not include copyholds, and therefore formerly it was necessary in order to enable a person to dispose of copyholds by will that he should first have surrendered them 'to the use of his will,' as it was called. This ceremony was rendered unnecessary by the statute 55 Geo. III, c. 192, which however does not extend to customary freeholds. A devise of copyholds by will may be made without observing the formalities prescribed by the statute of frauds (29 Car. II. c. 3), the terms of that statute not extending to copyholds. The Statute of Entails (13 Ed. I.), commonly called the Statute of Westminster the 2d, does not extend to copyholds; but in most manors a custom of entailing copyholds has prevailed. These entails might formerly be barred by a proceeding in the Lord's Court, analogous to a common recovery, or in the absence of a custom authorizing such a proceeding, by a mere surrender. And now by statute (3 & 4 Wm. IV. c. 74, § 50-54 inclusive) entails of copyholds may be barred by assurances made in pursuance of the provisions of that act. It is a general rule that no statute relating to lands or tenements in which those of a customary tenure are not expressly mentioned, shall be applied to customary estates, if such application would be derogatory to the customary rights of the lord or tenant. Hence neither the provision in the Stat. of Westm. the 2d, (13 Ed. I. c. 18) rendering debtors' lands liable to process of execution by writ of elegit, nor the Statute of Uses (27 Henry VIII. c. 10), nor the Statutes of Partition (31 Henry VIII. c. 1, and 32 Henry VIII. c. 32), nor the statute enabling persons having certain limited interests in lands, to grant valid leases (32 Henry VIII. c. 28), nor any of the local Registry Acts are applicable to copyholds.

Copyholds cannot be seized upon an outlawry, nor are they assets for payment of specialty debts at law, nor are they even liable for debts due to the crown, although they have always been subject to sequestration under the decree of a court of equity. But copyhold lands belonging to traders have been subjected to the operation of the bankrupt laws (v. stat. 6 Geo. IV. c. 16, sec. 68 and 69; 3 and 4 Wm. IV. c. 74, sec. 66;) and by stat. 3 and 4 Wm. IV. c. 104, copyhold lands of all persons whatever which have not been devised for payment of debts, are rendered assets to be administered in a court of equity for the payment of specialty and simple contract debts. Copyholds are not liable (except by special custom) to the incidents of curtesy or dower. The latter, where authorized by the custom, is called the widow's 'free bench.' These estates being considered continuations of that of the deceased tenant, are perfected without admittance. A purchaser or devisee of copyholds has an incomplete title until admittance; but the customary heir is so far legal owner of the land *before admittance* that he can surrender or devise it, or maintain an action of trespass or ejectment in respect of it. The lord may by a temporary seizure of the land compel an heir or devisee to come in and be admitted; and he is himself compellable by a mandamus of the Court of King's Bench to admit any tenant, whether claiming by descent or otherwise.

By the general custom of all manors, every copyholder may make a lease for any term of years, if he can obtain a license from the lord, and even without such license he may demise for one year, and in some manors for a longer term, and the interest thus created is not of a customary nature, but a legal estate for years, of the same kind as if it had been created out of a freehold interest. But every demise without license for a longer period than the custom warrants, and in general, every alienation contrary to the nature of customary tenure, as a feoffment with livery of seisin, is followed by a forfeiture to the lord. A copyhold estate may also be forfeited by waste; as by cutting down timber, or opening mines, when such acts are not warranted by the custom. In the absence of such special custom, the general rule seems to be that the right of property both in trees and mines, belongs to the lord, while only a possessory interest is vested in the tenant; but neither can the lord without the consent of the tenant, nor the tenant without the license of the lord, cut down trees, or open and work new mines. In like manner forfeiture may be incurred by an inclosure or other alteration of the boundaries of an estate, refusal to attend the customary courts, or to perform the services, or to pay the rent or fine incident to the tenure. The 9th section of the 1st Wm. IV. c. 65, protects infants, lunatics, and married women from the last mentioned cause of forfeiture. In case of felony or treason being committed by a copyholder, the lord has the absolute benefit of the forfeiture, unless it has been expressly provided otherwise by act of parliament. In all cases of forfeiture the lord may recover the forfeited estate by ejectment, without prejudice to the rights of the copyholders (if any there be) in reversion or remainder. He may waive the forfeiture by a subsequent act of recognition of the tenure. If he does not take advantage of the forfeiture for twenty years, his right to do so is barred by the act for the Limitation of Actions, 3 and 4 Wm. IV. And if he neglect to take advantage of the forfeiture in his life-time, his heir cannot avail himself of it.

The lord may also become entitled to a customary tenement by escheat for want of heirs. Formerly where a copyhold was surrendered to a mortgagee and his heirs, and no condition was expressed in the surrender, and the mortgagee died intestate and without an heir, the lord was entitled to enter for escheat. To remedy this, the 4 & 5 Wm. IV. c. 23, enacts that where a trustee or mortgagee of lands of any tenure whatsoever, dies without an heir, the Court of Chancery may appoint a person to convey or surrender the legal estate for the benefit of the persons entitled to the equitable interest in the property, and provides against the future escheat or forfeiture of lands by reason of the attainder or conviction of trustees or mortgagees who have no beneficial interest therein.

If the lord (having acquired a copyhold tenement by forfeiture, escheat, or surrender to his own use) afterwards grant it away by an assurance unauthorized by the custom, the customary tenure is for ever destroyed. And if he makes a legal conveyance in fee-simple of a copyhold tenement to the tenant, the tenement is said to be enfranchised, *i. e.* converted into freehold.

Copyholders were till very lately incapable of serving on juries, or voting at county elections of members of parliament; but the former disability was removed by 6 Geo. IV. c. 50, sec. 1, and the latter by the 2 & 3 Wm. IV. c. 45, sec. 19. As to the qualification for killing game under 22 and 23 Car. II. c. 25, sec. 3, there seems to be no distinction between freeholders and copyholders.

There are no lands of a copyhold tenure in Ireland.
